The present paper deals primarily with the activity of the catalysts. A satisfactory measure of activity, as has been pointed out in earlier papers^{2,4}, is the efficiency of the catalyst at a given temperature, or is the temperature corresponding to a given efficiency, when a "steady state" has been attained. It was found that a definite efficiency could be obtained for each catalyst provided that certain experimental conditions, as the temperature and volume of the catalyst, the rate of flow of the gas, and the partial pressure of water vapor, were kept constant. The results of the measurements, under controlled conditions, and in general with dry gas, are given in the form of efficiency-temperature curves, the efficiency being expressed as the percentage of the carbon monoxide oxidized in passing through the catalyst. The curves do not intersect, and their positions with reference to the temperature axis give a convenient measure of the relative activities of the catalysts.

In general, a very low concentration of carbon monoxide in air, approximately 0.2%, was used in these tests. Higher concentrations would have introduced a complication due to the greater heat of combustion in the mass of the catalyst. However, the precaution of measuring the temperature within the catalyst, when operating under constant conditions, prevented any error due to this heating effect. In fact, it was proved for one catalyst that the same efficiency-temperature curve was obtained when the carbon monoxide concentration was varied between 0.1% and 0.6%.

Preparation of the Catalysts

The manganese dioxide and copper oxide were prepared according to the directions of Merrill and Scalione⁷ except that larger quantities were used. However, we believe that products of this type made by different investigators or at different times may vary greatly in properties.

In the preparation of the *basic copper carbonate*, the directions of Merrill and Scalione⁸ were followed except that it was not precipitated on the manganese dioxide. The product was a fine, green precipitate and settled rapidly.

Three series of catalysts were prepared. Each consisted of six members, the pure components, and four mixtures of the following approximate compositions: 80% MnO₂, 20% CuO; 60% MnO₂, 40% CuO; 40% MnO₂, 60% CuO; 20% MnO₂, 80% CuO. The catalysts of each series will be referred to later by numbers from 1 to 6, in the order of decreasing manganese dioxide content.

In each series the moist constituents were mixed in the desired proportions, drained on a filter, and the six samples in the form of filter cakes dried slowly at about 75° for 72 hours in an electric oven. In each case the resulting material was broken up, and granules which passed a 10-mesh screen and were retained on a 20-mesh screen were collected and stored in well-stoppered bottles. Before these granules were tested or analyzed, they were given a final drying for half an hour at 175° under a pressure of about 1/3 atmosphere.

The catalysts of Series 1 were later found to contain soluble sulfates, and in some cases seemed not to have been well mixed. Accordingly, in the two later series the constituents were washed more carefully during their preparation, and the mixing was done by grinding the moist oxides in a large mortar until a uniform paste resulted. The basic copper carbonate (No 6, Series 3) had a tendency to pulverize on drying and did not give satisfactory granules. No. 5 in the same series gave very soft granules.

Three catalysts prepared by the Washington investigators were also tested: manganese dioxide, a 60% (MnO₂) mixture, and copper oxide. Portions of the original samples were given the usual half-hour heat treatment under diminished pressure at 175° before being tested. These catalysts are numbered W1, W3, and W6 respectively, but do not constitute a related series. The methods of preparation of the two oxides, W1 and W6, were similar to those used by us; but the mixture, W3, is not directly comparable with any of our mixtures. It is probably closely related to or identical with that used by Lamb, Scalione and Edgar. Its properties, which will be presented later, indicate that its constituents differed from those of the other mixtures, but may be partly accounted for by the pressure treatment to which the moist filter cake was subjected.

Apparatus and Experimental Method

The general method of testing consisted in passing a mixture of carbon monoxide and air of known composition through the catalysts at a definite constant rate and determining the percentage of the carbon monoxide oxidized by analyzing the effluent gas. Since it was desirable to make analyses continuously, use was made of a calorimetric device developed by Lamb and Larson, with a modification essentially like that described by Larson and White¹¹ for the prevention of premature combustion on the thermocouple leads.

The flowmeter, A, gave a head of 35.8 cm. of water for a rate of flow of $^{5}/_{12}$ liters per minute. This corresponds to the space velocity of 5000 for 5 cc. of catalyst which was used in these tests.

E is a bead tower through which concd. sulfuric acid dripped and G is a tower containing solid sodium hydroxide for removing acid spray.

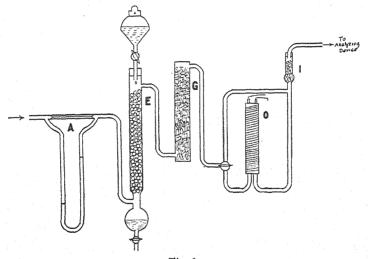

Fig. 1

The catalyst to be tested was placed in a tube at O. The testing tube was of 1 cm. cross section and the catalyst was placed therein on a perforated plate, to a depth of 5 cm. The gas passed up inside of the outer jacket and down through the catalyst contained in the inner tube. For tests above room temperature, heating was accomplished by a coil of resistance wire wound on asbestos paper around the outer tube, and the temperature was controlled by means of a lamp bank and a rheostat. The temperature within the catalyst and that just above it was measured by means of two copper-constantan thermocouples. Readings were made on a commercial potentiometer indicator to within 1° . When the catalyst was operating at 100% efficiency with 0.2% carbon monoxide air mixture, its temperature was 4° or 5° higher than that of the entering gas; but at 20% or lower efficiency the difference was not measurable. For tests below room

¹⁰ Lamb and Larson, This Journal, 41, 1908 (1919); compare Figs. 3 and 4, p. 1914.

¹¹ Larson and White, ibid., 44, 20 (1922).

temperature the entering gas was precooled before reaching the catalyst by passing through a copper tube, closely wound around the glass jacket. The apparatus was immersed in a Dewar tube containing a suitable cooling mixture and the temperature of the catalyst was measured as before.

In Fig. 1, I represents a calcium chloride drying tube, placed beyond the catalyst, which was used in all our work. It is probable that the drying of the gas at this point was unnecessary, since there is no evidence that water vapor interferes with the performance of the analyzing device.

The mixture of carbon monoxide and air used for testing was kept in a 500-liter gasometer, built of tin-plated copper and equipped with an electric fan for stirring. The carbon monoxide was prepared by the action of concd. sulfuric acid on sodium formate.

Analytical Methods

Carbon Monoxide.—The iodine pentoxide method for the determination of carbon monoxide was employed to determine the composition of the gas used for testing. The procedure followed was essentially the same as that developed by Larson, Jayson and White, Defense Research Section, C. W. S.¹² When small corrections were made by means of blanks, an accuracy of 1 to 2% was obtained for samples containing about 0.2% of carbon monoxide.

The composition of the catalysts, as determined by the following analytical methods, is shown in Tables I–IV, which are placed in the following section near the efficiency-temperature diagrams, Figs. 2–6.

Water and Carbon Dioxide in the Catalysts.—A current of air, previously dried by passing over solid potassium hydroxide and phosphoric anhydride, was aspirated slowly through a Pyrex tube containing a weighed sample of the catalyst, and then through weighed U-tubes containing phosphorus pentoxide and potassium hydroxide. The tube containing the catalyst was heated almost to redness and allowed to cool in position. The amounts of water and carbon dioxide were determined by weighing the absorption U-tubes. It is interesting to note that even the manganese dioxide (before its use as a catalyst) contained some carbon dioxide although no carbonate was used in its preparation. The only explanation is that it was absorbed from the air.

In Tables I–IV the results of these analyses are expressed as the number of grams of water or carbon monoxide per 100 g. of the water-free sample. The calculations were made by subtracting the weight of water found from the weight of the original sample. In Series 1 (Table I) the carbon dioxide content was very small and was neglected.

Available Oxygen.—The oxidizing power of the catalysts was determined by their ability to liberate iodine from a solution of potassium iodide, which was slightly acid with sulfuric acid. The oxidizing power thus determined includes the reduction of the manganese dioxide to manganese oxide and of the cupric to cuprous oxide. The liberation of iodine was

¹² Compare Teague, J. Ind. Eng. Chem., 12, 964 (1920).

slow, especially with copper present, and was not complete in some cases in less than two or three days. To prevent the oxidation of the iodide by the air during this period the solutions were kept in glass-stoppered flasks from which air had been displaced by carbon dioxide. The iodine set free was titrated with $0.1\ N$ sodium thiosulfate solution. After titration the solution was allowed to stand for 24 hours and if no color developed, the reaction was regarded as complete.

In Tables I–IV the available oxygen is shown in the fifth column as the number of grams of oxygen per 100 g. of the anhydrous sample (that is, the original material minus the water content).

An attempt was made to check the method described above by comparison with a gravimetric one. A sample of the oxide was treated as described under the determination of water, and the catalyst was weighed after the heating. The weight lost by the oxide minus the weight of water and carbon dioxide was taken as the amount of oxygen lost on heating. The available oxygen content of the same oxide before and after heating was determined by the potassium iodide method and the difference between these should also be equal to the oxygen lost. In almost every case, the oxygen loss as determined by the latter method was slightly greater than that found by the direct weighing. The discrepancy was mainly due to the fact that the oxide after being heated was extremely hygroscopic and gained some weight before it could be weighed. It was found that a momentary exposure to the air produced an appreciable increase in weight, and that the discrepancy became less as precautions to prevent exposure were increased. It was concluded, therefore, that the iodide method was the better and could be relied upon to give satisfactory results on the relative available oxygen contents of the catalysts used.

Copper Oxide.—The mixed catalyst was treated with dil. sulfuric acid and solid sodium sulfite, in excess of that required for the reduction of the manganese dioxide, was added. The oxides dissolved rapidly and the solution was evaporated until fumes of sulfuric acid appeared, in order to expel the excess of sulfur dioxide. The acid concentration was reduced to about $0.2\,N$ by addition of water, and excess of potassium iodide was added. The liberated iodine was treated with $0.1\,N$ sodium thiosulfate solution in the usual manner.

In Tables I–IV the results of these copper determinations are shown in the third from the last column as percentage of cupric oxide in the anhydrous sample.

Manganese Oxides.—After correction had been made for the water content, 100 g. of the anhydrous sample contained known amounts of carbon dioxide and cupric oxide and the remainder was assumed to be manganese oxides, MnO_x , (except in Series I, where the impurities were not negligible); x was calculated from the available oxygen content, after the

amount corresponding to the cupric oxide present had been subtracted. The values of x, given in the last column of the Tables, are always less than 2, and are not constant within a single series. While they are evidently not very accurate, they serve to show approximately the state of oxidation of the manganese oxide. Another method of representing the composition of MnO_x is shown in the tables, namely, as a mixture of manganese dioxide and monoxide; the fourth from the last column shows the amount of dioxide corresponding to the available oxygen in MnO_x , and the remainder is given in the next to the last.

The presence of impurities in the catalysts of Series 1 interfered with the determination of the MnO_x content and of x. The impurity was 4.5% in the copper oxide; and it was probably as large in the manganese oxide, No. 1, as was shown by its behavior towards water (in experiments by Draper which will be described in a later article). The value of x for this sample (No. 1) is 1.65 when the impurity is assumed to be zero, and 1.69 for 4.5% impurity. The latter value was arbitrarily assumed, and the 4.5% correction for impurities was made on all the members of Series 1.

The composition of the catalysts with respect to MnO_x and cupric oxide is shown in the second and third columns of Tables I–IV.

Results of Standard Efficiency Tests with Dry Gas

In making a run, air was passed through the line until the galvanometer deflection remained constant at or near the zero point. This indicated that the two thermocouple junctions in the analyzing device were in temperature equilibrium. The dilute mixture of carbon monoxide and air was then drawn through at a rate of 5/12 liters per minute directly to the analyzer and a constant deflection was obtained in a few minutes. By changing the resistance in the galvanometer circuit this constant deflection was made to occur at a position between 20 and 25 cm. on the scale. The gas was then turned through the catalyst tube by means of a stopcock; the reading then varied between the above maximum and zero, depending on the efficiency of the catalyst. For this analyzing device Lamb and Larson found that the calibration curve, relating deflections to carbon monoxide concentrations, was a straight line up to 0.4% of carbon monoxide. From this it follows that at these low concentrations the percentage decrease in the deflection is equal to the percentage of carbon monoxide oxidized in the catalyst tube. This gives the efficiency of the catalyst under the given conditions directly, provided that sufficient time has been allowed for a steady state to be realized.

In a given run, after the steady state had once been attained, giving one point on the efficiency-temperature curve, the determination of the other points could be made comparatively rapidly. When the temperature of the catalyst was then maintained constant for half an hour the efficiency

remained constant for the last 15 minutes of this period. However, on starting a run, either with a fresh catalyst or with a sample which had been tested on the previous day, there was some delay in attaining the steady state, and the efficiency gradually increased at constant temperature. This was especially marked when the catalyst was operating at low efficiency. Accordingly, the most satisfactory procedure was first to operate at or above the temperature corresponding to 90–100% efficiency. Each of the points marked on Figs. 3, 4 and 5 was obtained at constant temperature and the efficiency remained constant for 10 minutes. The points were shown to be reproducible whether the catalyst had previously been operating at higher or lower efficiencies.

In making the tests on Series 1 the less satisfactory method was adopted of beginning the measurements at the lower temperature, and taking a large number of readings without definitely proving that the efficiency remained constant at a given temperature. The smooth curves drawn

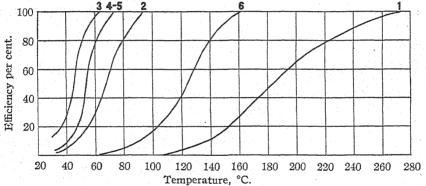

Fig. 2.—Efficiency data for Series I; compare Table I

through these points are shown in Fig. 2, but it is possible that the efficiency may be slightly low in some cases. However, when a second run was made with Catalyst 3 by the regular method, the steady-state points fell on or very close to the curve previously obtained.

The results in Fig. 2 show that the four mixtures were 100% efficient at temperatures below 90°, while the copper oxide, No. 6, and the manganese

dioxide, No. 1, did not reach this efficiency until the temperature was raised to 160° and 280°, respectively.

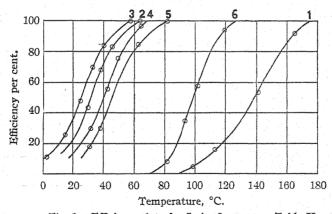

Fig. 3.—Efficiency data for Series 2; compare Table II

A comparison of Figs. 2 and 3 shows a distinct improvement in efficiency for the catalysts of Series 2, over the corresponding ones of Series 1. This is probably due to the fact that the oxides of Series 2 were washed free from soluble salts.

In Fig. 4 the results for Series 3, except for the poor efficiency of the basic copper carbonate, No. 6, are seen to be in close agreement with those for Series 2, Fig. 3. It is remarkable that the relatively high carbon dioxide content (see Table III) of the mixtures has so little effect. The water

content is also higher than in Series 2, but there is no reason to suspect that the catalysts were not operating in the region of maximum efficiency (compare the following section). In this series, as in the two earlier ones, the catalyst whose composition is closest to 60% of MnO_x and 40% of cupric oxide (No. 2 in this case) is the most active; but the difference between it and the other mixtures in the series is not great.

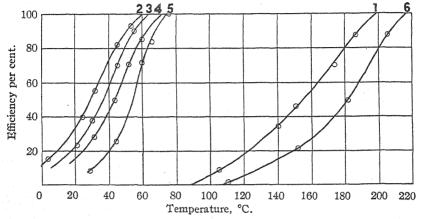

Fig. 4.—Efficiency data for Series 3; compare Table III

The efficiency-temperature curves for the Washington catalysts, Nos. 1 and 6, Fig. 5, correspond closely with those for Nos. 1 and 6 of Series 2, Fig. 3, for which the methods of preparation were similar. But the mixture, W3 (Curve 3), is a far more active catalyst than any of our mixtures;

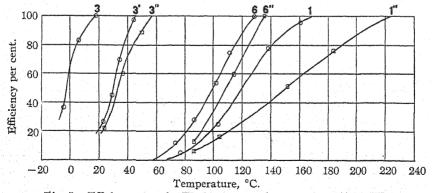

Fig. 5.—Efficiency data for Washington catalysts; compare Table IV

it operated at 100% efficiency below 20° , while no other did so below 55° . The analytical data in Table IV show that this catalyst is remarkable for the high content of oxygen in its MnO_x ; the value of x, 1.95, is higher than in any other sample. Its carbon dioxide content is relatively low (compare

Nos. 2 and 3, Table III). These facts suggest that there was some unknown but essential difference in the methods of preparing the constituents of this catalyst, but we do not know whether its high activity is to be attributed to such an explanation, or to the fact that the moist mixture of the constituents was subjected to high pressure. The data of Merrill and Scalione¹³ on the effect of pressure on the "life" of the catalyst in moist air probably do not throw any light on this question.

Variation of the Water and Oxygen Contents of the Catalysts

Other investigators have found that partial dehydration of the oxide catalysts is necessary in order to make them appreciably active. A rapid increase in activity is caused by the initial removal of water. This rate of increase, however, does not continue indefinitely, for a region is reached such that further slow dehydration causes a comparatively slight change in the activity. For example, in the case of Catalyst 3, Series 1 (approximately 60% of manganese dioxide and 40% of cupric oxide) a decrease in the water content from 12% to 7.5% (referred to the water-free material) reduced the temperature required for 50% efficiency only from $49\degree$ to $45\degree$. The removal of water up to this point did not cause an appreciable decrease in the oxygen content of the catalyst.

Reference to the tables of the preceding section shows that the water content of the mixed catalysts did not differ greatly within a given series, and was for each catalyst probably in the region where the change of activity with dehydration was slight. Since all were submitted to a similar drying process, the variation of the water content indicates the relative ease with which each lost water. In Series 1 and 2 the manganese dioxide was the more hydrated and the water content of the mixtures decreased with the manganese dioxide content. In Series 3 there was a trend in the opposite direction because the basic copper carbonate contained the more water.

¹³ Ref. 3, p. 1995, Table III.

It was found that continued drying of the catalyst, beyond the region referred to above, resulted in decreased activity, and loss of oxygen except in the case of copper oxide. A sample of the Washington mixture, No. 3" Table IV and Fig. 5, was dried over a moving flame for a short time. Comparison with No. 3 shows a great lowering of activity when the water content had been changed from 6.2 to 4.3 and the oxygen content lowered from 13.6 to 12.8. Another example of the loss of a small amount of oxygen in drying is furnished by the results for No. 3, Series 1 in Table V below. Data for the Washington samples of copper oxide and manganese dioxide are given in Table IV and Fig. 5. The efficiency of a sample of copper oxide, No. 6', which contained 3.7% of water was found to be coincident with Curve 6 (2.9% of water); but the activity was ultimately reduced by further drying at a higher temperature (compare No. 6"). The oxygen content was unchanged. In the case of the manganese dioxide loss of oxygen occurred before the decrease in activity. Thus, No. 1', which had been dried under suction for two hours at 200° and contained 10.5% of water, showed an efficiency corresponding to Curve 1 (15.2% of water), although its oxygen content had been changed from 15.6 to 14.6. Continued drying at higher temperature reduced the efficiency to that represented by Curve 1", and lowered the oxygen content to 13.4. It seems probable from these results that the decrease in activity finally obtained is due to a change of structure. The active mixed catalyst is sensitive to loss of oxygen, while the much less active manganese dioxide is not.

The high oxygen content of the most active catalyst, W3, has already been referred to and, as implied in the preceding paragraph, it is possible that there is a relation between the content of available oxygen of a mixed catalyst and its activity. However, even if this should prove to be true, oxygen comparisons would have to be restricted to samples of the same catalyst which had been subjected to various treatments. From our data for Series 1 to 3 we have found no relation between the values of x, Tables I to III, and the relative activities of the various catalysts.

Merrill and Scalione considered that the oxygen content of a catalyst is one of the variables at the steady state, and reported¹⁴ that the catalyst, when operating at low efficiency with either dry or wet gas, lost oxygen which was restored by operation at higher efficiency. We, however, have been unable to check this result. In each of the four sets of experiments in Table V, the oxygen content is seen to be practically the same whether the catalyst was operated at low or high efficiency. In each experiment the catalyst was operated for from one hour to two hours with dry gas at the efficiency stated before a sample was taken for analysis. These results are not conclusive, since the amount of oxygen that could be removed in one hour from a catalyst operating at low efficiency with 0.2% to 0.4% of

¹⁴ Ref. 3, pp. 1993 and 1997.

carbon monoxide does not exceed the possible limit of error in the analysis. But our failure to detect an increase of the oxygen content in any sample of a catalyst operating at high efficiency, and the result given in a later section that the speed of reduction is slower than the speed of catalysis, make it probable that there is no appreciable change in the oxygen content of the catalyst.

Tests with Moist Gas

The effect of moisture on the operation of these catalysts has been studied extensively by the earlier investigators. For example, Merrill and

Scalione¹⁵ gave efficiency-temperature curves for gas of varying humidity, which show that the water vapor causes a decided decrease in activity. From these and other results, they concluded that the moisture absorbed from the gas remains for the most part as a film on the surface of the catalyst, hindering the adsorption of carbon monoxide and oxygen, and does not re-hydrate the oxides to any considerable extent. This film was removed by Fig. 6.—Efficiency-temperature curves for dry operation with dry gas at higher

and moist gas

temperatures and the catalyst gradually regained its former activity.

In order to check these observations and to obtain comparable efficiency-temperature curves for dry and moist gas, some tests were made on Catalyst 2 of Series 2. Vapor pressures of 11.5 mm. and 5.1 mm. were obtained by allowing 44% and 58% sulfuric acid solutions to drip through the bead tower. The steady-state points were obtained as in the dry gas tests

¹⁵ Ref. 3, p. 1998.

and were found to be quite reproducible whether approached from higher or lower efficiencies. Contrary to the results of Merrill and Scalione, no decrease in the oxygen content was detected for samples which had been operating at low efficiencies. In Fig. 6, A represents the efficiency for dry gas, B for water-vapor pressure of 5.1 mm. and C for vapor pressure of 11.5 mm.

The fact that water vapor is strongly adsorbed and tends to form a film on the surface of the catalyst, indicates that this equilibrium film is the retarding factor which accounts for the decreased efficiency of the catalyst with moist gas. The similar form of the curves for moist gas and dry gas suggested the presence of a strongly adsorbed film, when operating with dry gas also, which might be the limiting factor in the catalysis. It seemed likely that carbon dioxide would be the more strongly adsorbed, of the gases concerned and would, therefore, be more apt to exert such a covering action. It was thought that the addition of carbon dioxide to the testing gas might cause a decrease in efficiency, if the catalyst had a tendency to take on such a film of carbon dioxide. However, the results of some experiments on Catalyst 3 of Series 2, with a partial pressure of carbon dioxide of 1/3 atmosphere, indicated that there was no marked effect. Since in the absence of added carbon dioxide the partial pressure of carbon dioxide in the gas leaving a catalyst operating at 100% efficiency would be only 0.002 atmosphere, it follows that an increase in the carbon dioxide pressure of 167 fold (or more when the catalyst is operating at lower efficiency) has little or no effect. This result does not prove that there is no protective film of carbon dioxide, but simply that such a film, if it exists, is not in equilibrium with the surrounding gas. In other words, this is a question of rate and not of equilibrium, and it is possible that the carbon dioxide is given off so slowly by a catalyst operating at low efficiency that a film is built up at the steady state. Definite evidence in favor of this mechanism will be presented in a later paper.

The Reduction of the Catalyst by Carbon Monoxide

The probability that the oxygen content of a catalyst remains practically constant has already been mentioned. In order to obtain data on the ease of reduction of the catalysts some runs were made with a mixture of about 1% of carbon monoxide in nitrogen. Oxygen was removed by means of yellow phosphorus, and the mixture was passed through the catalyst at the rate of 300 cc. per minute. Air was admitted to the gas stream after passing the catalyst in order that the analyzing device might be used to measure the change in the carbon monoxide content of the gas; the rate of flow of air was maintained constant at about 420 cc. per minute by means of another flowmeter. Before an experiment was begun nitrogen was passed through the system for half an hour to sweep out oxygen.

The behavior of Catalyst 3 of Series 2 was typical for all experiments started at a temperature close to that at which the catalyst operated at 99-100% efficiency with carbon monoxide in air, and will be described in detail. The experiment was begun with the catalyst at a temperature of 56° (compare Fig. 3), and its behavior is shown graphically in Fig. 7.

The initial reading of 23.0 corresponds to the concentration of carbon monoxide in the nitrogen mixture, which was 0.86% as determined by the iodine pentoxide method. When the gas was turned through the catalyst (fourth minute) the drop in the reading indicated a very rapid reaction and the temperature of the catalyst rose from 56° to 63° during the first 9 minutes. As shown by the curve the rate of carbon monoxide oxidation then became progressively slower and seemed to be practically constant between the times 40 and 65 minutes. The catalyst temperature had now returned to 58° . Between the times 65 and 85 minutes the temperature of the catalyst was raised to 86° and the decreasing deflections showed that

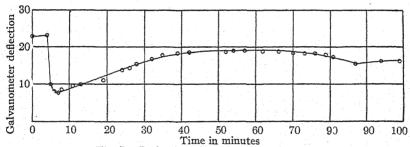

Fig. 7.—Reduction of catalyst by carbon monoxide

carbon monoxide was then being oxidized, at the expense of the catalyst, more rapidly at the higher temperatures. While the rate of this reaction and the temperature were still increasing the input of heat was decreased; this corresponded to the gradual rise of the curve, indicating at the end of the experiment 22% oxidation at a temperature of 84° .

A sample of the catalyst taken immediately after the run showed a loss of 16.3 mg. of oxygen per gram of the anhydrous sample, which corresponds to about 10% of the available oxygen originally present. From the amount of carbon monoxide oxidized during the run, and the weight of the sample, 1.38 g., an approximate calculation of the oxygen loss was made, which agreed fairly well with the above figure, thus showing that the gas mixture was practically free from oxygen. It was found that, unless extreme precautions were taken to remove all the oxygen, the carbon monoxide combined with this oxygen in preference to reducing the catalyst.

The partially reduced catalyst was then treated with the usual mixture of carbon monoxide and air for two hours. It then showed an efficiency of but 10% at 55° and of 80% at 82° , while the same catalyst before reduction

was 100% efficient at 60°. Analysis of the sample showed that over half of the lost oxygen had been restored by this air treatment. The failure of the catalyst to return to its former state of activity, in spite of the partial restoration of oxygen, suggests that it had suffered a change of structure. The efficiency of the more active mixed Washington catalyst was also found to be permanently impaired by similar reduction (at 30–38°) with carbon monoxide, but in this case there was little evidence to indicate that any of the lost oxygen was regained in the subsequent operation of the catalyst with carbon monoxide in air. These results support the suggestion made in a previous section that the oxygen contents of samples of a given mixed catalyst may indicate the relative activity.

A similar experiment at a higher temperature (150–166°) with the manganese dioxide of Series 2 showed that its efficiency was not permanently lessened by reduction to the extent of 7% of its available oxygen. It returned to its former activity when treated with carbon monoxide and air, and analysis showed that most of the lost oxygen had been restored. It has already been pointed out above that the active manganese dioxide catalyst is not very sensitive with respect to a change in the oxygen content. Whether this fact and the restoration of the oxygen lost in reduction are due simply to the high temperature necessary for operation as a catalyst, or can be taken as evidence that the mixed catalysts possess a structure different from that of the one-component catalysts, we are unable to decide.

In the reduction experiment begun at a temperature at which the catalyst could act with 99 to 100% efficiency as a catalyst, there action was very fast only for the first few minutes, after which its speed decreased fairly rapidly. It follows that there is only a small supply of "active" oxygen at the surface of the catalyst, and that the removal of oxygen from the catalyst becomes increasingly difficult as the reaction proceeds. The speed of the latter slow reaction increases rapidly with the temperature, and hence must be negligible at low efficiency. Similarly, the initial reaction is slow when the experiment is started at these lower temperatures. The simplest explanation of the decrease of the rate as the reaction proceeds and as the temperature is lowered is that the solid surface is protected by a film which is then held more firmly.

Our results show that at a given temperature the catalytic process cannot be replaced by a series of alternate treatments with carbon monoxide and air, at least unless the duration of each single treatment is made very short. The simultaneous reaction of the catalyst with carbon monoxide and oxygen takes place more rapidly than the reaction with carbon monoxide alone at the same temperature.

Discussion of the Mixture Effect

The relation of the compositions of the catalysts to their activity is best shown by the temperature-composition diagram, Fig. 8. Here the ordinate

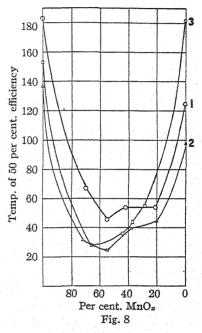

represents the temperature corresponding to 50% efficiency and the abscissa gives the percentage of MnO_x in the anhydrous mixture. The values of MnO_x were given in Tables I to III and the temperatures of 50% efficiency were read from Figs. 2 to 4. The numbers 1, 2 and 3 at the right-hand side of the figure refer to the three different series.

The striking result is the rapid increase, in all cases, of the activity of the one-component catalyst on the addition of small amounts of the second component. Evidence is therefore lacking of any fundamental difference between this example of co-activation of catalysts, and the promoter action

of an inert substance on a catalyst. Our results also indicate that the mixture of 60% of MnO_x and 40% of cupric oxide is but slightly more active than other mixtures, and that basic copper carbonate as a component has little, if any, advantage over copper hydroxide.

The following theory of the mixture effect in this case, which was developed early in the investigation, proved useful throughout our work, and will be discussed in connection with additional evidence in a later paper.

By the action of carbon monoxide and oxygen a protective film is formed on the catalyst which interferes with further action, unless it can be rapidly desorbed as carbon dioxide. The film builds up to a lesser extent for mixtures than for the one-component catalysts at the same temperature.

The slow limiting reaction may be the rate of desorption of carbon dioxide or the rate of a transformation within the film. We could stop with the statement that this is a question of the structure of the catalyst, but it seemed worth while to seek an interpretation in terms of valence theory.

The porous granules are believed to consist of a network of chains of atoms held together by valence forces. ¹⁶ The forces that come into play

16 Compare Langmuir, This Journal, 38, 2285 (1916).

The formation of the firm porous granule from the hydrated oxide or oxides may be thought of as follows. Each hydrated oxide is precipitated in the form of minute particles, the size of which is determined by the method of precipitation, but is greater than molecular dimensions. The filter cake, before it is dried consists of particles surrounded by films of water, which enable the relative positions of the particles to be easily changed for example, in a kneading process. In the preliminary drying as the water is slowly expelled, the particles are gradually drawn together, and in many places contact is suffi-

at or in the film are also valence forces. When the catalyst contains the two oxides, they will tend to neutralize each other's valence forces, since they differ in basicity or polarity, and the strength of the valence forces at the film may be expected to be less than for a one-component catalyst. In other words, an increase in the rate of desorption, or increase in the rate of a reaction within the film, is attributed to what may be considered a partial chemical reaction between the two oxides.

Summary

Temperature-efficiency curves have been obtained for three series of partially hydrated, porous catalysts of manganese dioxide and cupric oxide. Pronounced improvement in activity is caused by the addition of a small amount of either oxide to the other.

Partial dehydration is necessary to bring a catalyst to the region of maximum activity, but the water content may then be lowered to a relatively small value by slow dehydration with but little change in the efficiency. Continued dehydration, however, finally lowers the efficiency, and causes loss of oxygen (except in the case of copper oxide).

The efficiency of a catalyst is independent of the carbon monoxide concentration between 0.1 and 0.6%, and is practically unchanged by the presence at high concentration of carbon dioxide, the product of the reaction.

Water vapor has a marked poisoning effect, which is reversible.

It is probable that under steady-state conditions the oxygen content of a catalyst is practically constant whether the catalyst is operating at low or high efficiency.

A catalyst is reduced when treated with carbon monoxide in the absence of oxygen at a temperature at which it would act as a catalyst. The activity of a mixed catalyst is permanently impaired by this reduction, even when much of the lost oxygen is restored on subsequent operation as a catalyst.

A theory for the mixture effect in this case has been suggested.

BERKELEY, CALIFORNIA

ciently close to allow valence forces to come into play between the molecules of different particles. The plastic material has now been transformed into a solid. Finally, as the water of hydration is gradually expelled, the body becomes porous.

THE VAPOR PRESSURE OF MONATOMIC ELEMENTS

By Russell W. Millar Received July 23, 1923

The differential equation, $\frac{dp}{dT} = \frac{\Delta H}{T\Delta V}$, which expresses the change of va-

por pressure with the temperature in terms of the heat of vaporization and the change of volume, has been integrated heretofore for the purpose of obtaining a vapor-pressure equation. The equation derived contained a "chemical constant" which depended only upon the element under consideration. This constant was determined from the quantum theory, from the relation of Nernst, $C = -1.60 + 1.5 \log w$, where w is the molecular weight of the monatomic gas, or most accurately from two vapor-pressure measurements. It was then possible, using either of the first two methods of determining the chemical constant, to construct an entire vapor-pressure curve from specific heat data of the condensed phase and one point on the vapor-pressure curve.

Investigators² who have provided us with a method of calculating the entropy of a monatomic gas have made possible a simple and straightforward integration of the differential equation. The expression obtained is probably more convenient than that of Nernst for the purpose of calculating vapor pressures in unexplored ranges of temperature.

If we neglect the volume of the condensed phase and let V represent the molar volume of the gas, and assume that pV = RT, we have, from the above

$$\frac{\mathrm{d}\ln p}{\mathrm{d}\ln T} = \frac{\Delta H}{RT} = \frac{\Delta S}{R},\tag{1}$$

an equation used recently by Hildebrand.³ ΔS is the entropy of vaporization, namely $S_g - S_c$, where S_g is the entropy of the gas and S_c that of the condensed phase.

If we express p in atmospheres, then we have from Lewis' theory of ultimate rational units

$$S_g = R \ln (T^6/2w^3/2/p) - 2.63$$
 (2)

where w is the molecular weight of the gas. Also

$$S_c = S_0 + \int_{T_0}^T C_p \, \mathrm{d} \ln T,$$

¹ Nernst, "Theoretische Chemie," Macmillan and Co., 7th ed., 1916, pp. 236, 756. F. Born, Ann. Physik, 69, 473 (1922). Trautz and Stäckel, Z. anorg. Chem., 122, 81 (1922). Henglein, ibid., 123, 137 (1922).

⁴ Lewis, Gibson and Latimer, *ibid.*, 44, 1008 (1922).

neglecting the effect of change of pressure upon the entropy of the condensed phase. Here S_c is the entropy of the condensed phase at some temperature T_0 , and C_p is its molar heat capacity at constant pressure. Now C_p must be expressed as some function of the temperature which will be integrable in the expression above and also give a result which will leave Equation 1 integrable. The simplest function is $C_p = \alpha + \beta \ln T + \gamma (\ln T)^2$. Of course, this function does not express exactly the relation between C_p and T over any extended temperature range, yet it was found that quite accurate calculations of vapor pressure over temperature ranges sufficiently long could be made when γ , and even in some cases β , were omitted. Omitting γ , the inclusion of which, however, in no way complicates the integration of Equation 1, we obtain

$$S_c = S_0 + \alpha \ln T + \frac{\beta}{2} (\ln T)^2 - \alpha \ln T_0 - \frac{\beta}{2} (\ln T_0)^2$$
 (3)

Substituting Equations 2 and 3 in 1, we have

$$\frac{\mathrm{d} \ln p}{\mathrm{d} \ln T} + \ln p = \left(2.5 - \frac{\alpha}{R}\right) \ln T - \frac{\beta}{2R} (\ln T)^2 + \frac{1}{R} \left[1.5 R \ln w + \alpha \ln T_0 + \frac{\beta}{2} (\ln T_0)^2 - 2.63 - S_0\right]$$

This is a differential equation linear with respect to the dependent variable and of the form $\frac{dy}{dx} + y = ax - bx^2 + K$, of which the solution is $y = (a + 2b)x - bx^2 + Ze^{-x} - a + 2b + K$, where Z is the constant of integration. Likewise

$$\ln p = \left(2.5 - \frac{\alpha - \beta}{R}\right) \ln T - \frac{\beta}{2R} (\ln T)^2 + \frac{Z}{T} - \left(2.5 - \frac{\alpha - \beta}{R}\right) + \frac{1}{R} \left[1.5 R \ln w + \alpha \ln T_0 + \frac{\beta}{2} (\ln T_0)^2 - 2.63 - S_0\right]$$

Using common logarithms, we have

$$\log p_{\text{atm.}} = \left(2.5 - \frac{\alpha - \beta}{R}\right) \log T - \frac{2.303 \,\beta}{2R} (\log T)^2 + \frac{Z}{T} + \frac{1}{R} \left[1.5 \,R \log w + \alpha \log T_0 + \frac{2.303 \,\beta}{2} (\log T_0)^2 - \frac{2.63 + S_0 - (\alpha - \beta) + 2.5R}{2.303}\right]$$

Therefore, if, for a condensed phase of any element which vaporizes to a monatomic gas, we know the values of α , β , and the entropy S_0 at some temperature T_0 , and one vapor-pressure measurement, such as the boiling or sublimation point, by means of which Z may be evaluated, the complete vapor-pressure curve for that phase over the temperature range for which α and β are valid may be calculated.

In Table I the calculated values for mercury, sodium, zinc and hydrogen have been compared with the observed values of various investigators. These calculations will now be made to illustrate the use of the equation. The elements named do not by any means exhaust the number of those for which the necessary data exist.

Mercury.—According to Barnes,⁵ the heat capacity of mercury above 120° is about 6.65. Taking this value as constant, and taking with Lewis, Gibson and Latimer $S_0 = 17.81$ at $T_0 = 298^{\circ}$ A., and from Smith and Menzies⁶ the value of the boiling point, 357° C., we obtain

$$\log p_{\text{mm}} = -0.8443 \log T - \frac{3319.6}{T} + 10.5134 \tag{4}$$

Since the heat capacity of mercury increases slightly with decreasing temperature below $160\,^{\circ}\text{C}$., a new equation was used below $120\,^{\circ}\text{C}$. to calculate the vapor pressure at temperatures as far down as the freezing point. In this range Barnes⁵ gives $C_p = 6.70$ (average), and we may take the same value of S_0 and T_0 as before. In order to calculate Z we may take either the calculated or observed value of p. Taking the latter as $0.829\,$ mm. at $394.9\,^{\circ}\text{A}$, we obtain a slightly different equation:

$$\log p_{\text{mm}} = -0.8694 \log T - \frac{3320.2}{T} + 10.5838 \tag{5}$$

which we can use below 120°C. The values given by this equation are slightly higher than those given by the preceding equation in the lower range of temperature. The results are as accurate as the value of the heat capacity chosen, which, though an average, differs but little from the extreme values.

We are now in a position to calculate the vapor pressure of solid mercury. The data of Pollitzer⁷ for the heat capacity of solid mercury from about 60° A. to the melting point may be expressed with considerable accuracy by $C_p = 1.118 + 1.016$ ln T. At the melting point, $T_0 = 234.1$, $S_0 = 13.80$. Evaluating Z from the calculated value of p at 234.1° A., we obtain

$$\log p_{\text{mm}} = 1.4487 \log T - 0.5882 (\log T)^2 - \frac{3621.7}{T} + 9.6814$$
 (6)

for solid mercury. At the temperature of boiling liquid air, about 90°A., we find $p = 1 \times 10^{-30}$ mm.

Sodium.—E. Griffiths, and Griffiths and Griffiths have measured the heat capacity of sodium for a short distance above the melting point. In the absence of more data, the equation $C_p = 7.40$ has been assumed to hold throughout the range to the boiling point. Using Lewis, Gibson and Latimer's value, $S_{298} = 12.2$, calculating $S_{370.6} - S_{298} = 1.5$ from the data of E. Griffiths and using Iitaka's value of the entropy of fusion, $\Delta s = 1.6$, we obtain at the melting point, $T_0 = 370.6$ °A., $S_0 = 15.3$ for liquid sodium. Gebhardt¹¹ gives, at T = 813°A., p = 18.5 mm.

- 5 Barnes. Rept. Brit. Assoc. Winnipeg, 1909, p. 403.
- 6 Smith and Menzies, THIS JOURNAL, 32, 1434 (1910).
- 7 Pollitzer, Z. Elektrochem., 19, 513 (1913).
- 8 E. Griffiths, Proc. Roy. Soc., 89A, 561 (1914).
- 9 Griffiths and Griffiths, Phil. Trans. Roy. Soc., 213A, 119 (1913).
- 10 Iitaka, Sci. Rep. Tôhoku Imp. Univ., 8, 99 (1919).
- 11 Gebhardt, Dissertation, Erlangen, 1903.

The equation then becomes

$$\log p_{\rm mm.} = -1.20 \log T - \frac{5135}{T} + 11.071 \tag{7}$$

For solid sodium we obtain from E. Griffiths $C_p = -20.2808 + 4.6869$ lnT, an equation which reproduces the results fairly accurately from room temperature to the melting point. Taking T_0 as equal to the melting point 370.6°A., $S_0 = 13.7$, and evaluating Z from the calculated value of p at 370.6°A., we obtain

log
$$p_{\text{mm}}$$
. = 15.0560 log T —2.7136 (log T)² - $\frac{7091.9}{T}$ - 4.6050 (8)

This equation gives $p = 1.7 \times 10^{-8}$ mm. at 298°A.

Zinc.—According to Iitaka,¹⁰ the heat capacity of liquid zinc is 7.91 and is nearly independent of the temperature. The same observer gives 2.19 as the entropy of fusion. Using his data for the heat capacity of solid zinc from 298°A. to the melting point, and $S_{298} = 9.83$ as given by Lewis, Gibson and Latimer, we obtain $S_0 = 17.46$ for liquid zinc at the melting point, $T_0 = 692$ °A. The boiling point of zinc is taken as 1193°A. From these data we obtain

$$\log p_{\text{mm}} = -1.4779 \log T - \frac{68336}{T} + 13.1558 \tag{9}$$

Iitaka's values of the heat capacity of zinc from room temperature to the melting point are fairly well represented by $C_p = -1.7437 + 1.3550$ ln T. Taking $T_0 = 298$ °A., $S_0 = 9.83$, and the vapor pressure at the melting point as calculated from Equation 9 we obtain

$$\log p_{\text{mm}} = 4.0583 \log T - 0.7845 (\log T)^2 - \frac{6823.1}{T} + 3.7555 \tag{10}$$

Hydrogen.—According to Eucken,¹² the heat capacity of hydrogen gas below 60°A. is that of a monatomic gas, and consequently Lewis, Gibson and Latimer⁴ have applied the Sackur equation to the calculation of the entropy of hydrogen gas at the boiling point. If that application is valid, we are justified in using the method of this paper to calculate the vapor pressure of hydrogen.

Keesom and Onnes, ¹⁸ and Eucken ¹² give consistent values for the heat capacity of liquid hydrogen which may be represented closely by $C_p = -6.14 + 3.55 \ ln \ T$. Keesom and Onnes ¹⁸ measurements of the heat capacity of solid hydrogen give 0.6 as the molar entropy of hydrogen at the melting point, 14°A. The same authors, and also Dewar, ¹⁴ have determined the molar heat of fusion of hydrogen to be about 30, from which we find 2.14 as the entropy of fusion. Taking, then, $S_0 = 3.00$ at

¹² Eucken, Ber. physik. Ges., 18, 4 (1916).

¹³ Keesom and Onnes, Comm. Phys. Lab. Leiden, 153a (1917).

¹⁴ Dewar, J. Chem. Soc., 73, 528 (1898).

 $T_0 = 14$ °A., and Cath and Onnes' 15 boiling point, 20.39 °A., we obtain

$$\log p_{\text{mm}} = 7.3725 \log T - 2.0572 (\log T)^2 - \frac{26.8679}{T} - 1.9280$$
 (11)

The values given by this equation do not, however, agree with the experimental values of Keesom and Onnes.

It will be noted that the vapor-pressure equation is of the form, $\log p = A \log T + B(\log T)^2 + \frac{Z}{T} + C$, and that A and B are determined solely by the heat-capacity curve of the condensed phase, here liquid hydrogen. If Keesom and Onnes' and Eucken's determinations of this curve are correct, and if, indeed, the application of the Sackur equation to gaseous hydrogen at these temperatures is valid, we should be able to obtain a vapor-pressure equation by evaluating both Z and C by means of two determinations of the vapor pressure. It will be noted that here we are not depending upon any of the experimental determinations of the heat

capacity of solid hydrogen and the heat of fusion of hydrogen, since S_0 occurs only in the constant C. The equation obtained by this method is

$$\log p_{\text{mm}} = 7.3715 \log T - 2.0572 (\log T)^2 - \frac{40.733}{T} - 1.2537$$
 (12)

It will be noted in Table I that the calculations from this equation agree with the determinations of Keesom and Onnes but little better than those from Equation 11. The failure of Equation 12 indicates that the Sackur equation is not applicable, that the heat-capacity measurements of Keesom and Onnes are uncertain, or that the vapor-pressure measurements are themselves uncertain, or a combination of these circumstances.

Finally, a calculation of the heat of fusion was made on the assumption that Keesom and Onnes' values of the vapor pressure and the heat capacity of the solid are correct, and that the application of the Sackur equation is valid. From the last we calculate the entropy of gaseous hydrogen in equilibrium with the solid at the melting point, $14^{\circ}A$. The pressure, as extrapolated beyond the last value of Onnes at $14.2^{\circ}A$., is 55.27 mm. We obtain $S_{\rm gas}=17.29$. From the vapor-pressure curve the entropy of vaporization is 15.34 at $14^{\circ}A$. If the entropy of solid hydrogen at the melting point is 0.6, then the entropy of fusion is 17.29—(0.6+15.34)=1.35, and the heat of fusion is 18.9 cal./mole.

It will be noted that the calculated values are as accurate as the specificheat data used in the formulas, and in the case of the best known vaporpressure measurements, namely, those of mercury, the agreement between the observed and calculated values is best. Unfortunately, the values of the specific heats in the neighborhood of the boiling points are extrapolated over a long range, so that accurate values of the heats and entropies of vaporization at the boiling points cannot be calculated.

¹⁵ Cath and Onnes, Comm. Phys. Lab. Leiden, 152a (1917).

Of course the same method can be used to calculate the partial pressure at a series of temperatures of a monatomic gas in equilibrium with any solid or liquid phase of constant composition for which the specific-heat curve and entropy are known, providing one value of the partial pressure is known.

Summary

A formula has been derived by means of which the pressure of a monatomic gas in equilibrium with the liquid or solid element can be calculated from specific-heat data and one vapor-pressure measurement.

Sample calculations have been made for mercury, sodium, zinc and hidrogen.

PROMOTER ACTION IN THE DECOMPOSITION OF POTASSIUM CHLORATE

By Harvey A. Neville Received July 26, 1923

Introduction

In an extensive research upon the catalytic decomposition of potassium chlorate¹ it was discovered that commercial manganese dioxide, or pyrolusite, was more active than the pure material in accelerating the evolution of oxygen. Analysis of the pyrolusite showed the presence of 8.8% of ferric oxide, Fe₂O₃, as an impurity. A mixture of pure manganese dioxide and ferric oxide in the proportions given by the analysis was then made and used as a catalyst. This mixture showed almost exactly the same activity as the pyrolusite, indicating that ferric oxide exerts a promoter action upon manganese dioxide in catalyzing the decomposition of potassium chlorate. The activities of these oxides separately and mixtures of the two as catalysts were measured at three different temperatures and the action of cupric oxide as a promoter with manganese dioxide was also studied.

Experimental Part

Apparatus.—The apparatus and method used in these experiments did not differ essentially from that described in other recent papers on this decomposition. The apparatus is indicated in Fig. 1. The reaction tube was heated by the condensation of

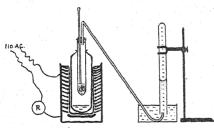

Fig. 1.—Apparatus

the vapor of a constant-boiling substance. The decomposition of potassium chlorate is exothermic and such a method of heating tends to act as a thermostatic arrangement; when the temperature of the reaction mass begins to rise above the boiling point of the liquid, heat is absorbed by the vaporization of liquid condensed on the reaction tube, which should be of thin glass for this reason.

Materials.—Fine crystals of the purest

potassium chlorate were used. The catalyst materials were finely ground pyrolusite, pure manganese dioxide made by the method of Georgen,² and cupric oxide made by oxidizing the pure metal, dissolving this oxide in nitric acid and decomposing the nitrate at 300°. Mixtures of catalysts were made both directly and by mixing the nitrate of one metal with the oxide of the other and heating to decomposition. The latter method gave more consistent results.

¹ The recent report of a similar investigation makes a complete presentation of results inadvisable at present. Compare Brown, Burrows and McLaughlin, This Journal, 45, 1343 (1923).

² Georgen, Compt. rend., 88, 797 (1879).

Procedure.—A sample for an experiment was prepared as follows. The potassium chlorate and catalyst in weighed proportions were finely ground, thoroughly mixed, moistened with water and dried. In this way the catalyst and potassium chlorate were brought into very intimate contact. A sample consisted of 6 g. of potassium chlorate plus an amount of the catalyst calculated as a certain percentage of the total weight. In the study of promoter action the catalyst was always 25%; that is, the mixture contained 6 g. of potassium chlorate and 2 g. of catalyst.

Results.—The results of the experiments at 328° are graphically represented in Figs. 2 and 3. The decomposition at this temperature is

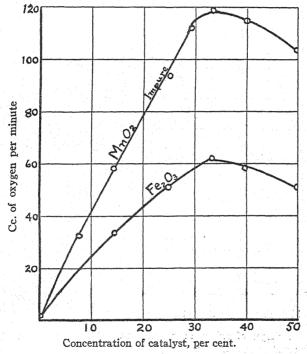

Fig. 2.—Rate of oxygen evolution with different amounts of catalyst

fairly steady and rapid and the temperature is safely below the melting point of potassium chlorate. At the other temperatures used (235° and 300°) the effects are exactly analogous, though less pronounced. The three oxides indicated are the only ones which have a marked catalytic activity at these temperatures. Above the melting point of potassium chlorate any finely divided solid accelerates the decomposition. As a basis for comparison it is to be noted that pure potassium chlorate at 328°, under the conditions of these experiments, evolves oxygen at the rate of 1 cc. per minute.

Discussion

The figures given for the rate of decomposition of potassium chlorate are not claimed as absolute values but are relative only. They are closely reproducible under the conditions of these experiments. The results obtained in any set of experiments will depend upon so many variable factors that no agreement will be possible except under those exact condi-

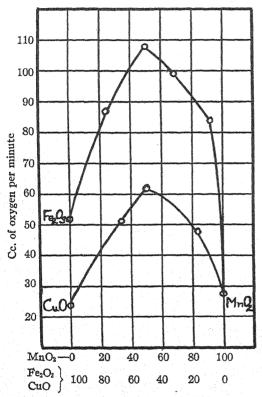

Fig. 3.—Percentages of oxides in mixture and rate of gas evolved at 328° from 6 g. of potassium chlorate mixed with 2 g. of catalyst

tions. Purity, melting point and previous treatment of the potassium chlorate, physical condition of the catalyst method of mixing and rate of heating are especially important factors.

In a recent article on promoter action A. Pickles³ suggested that if the atomic number of the metal present in a catalyst be even, the promoter should contain a metal of odd atomic number, and vice versa. A number of instances were cited where this is true. There are, however, many obvious exceptions, but it is apparent from a consideration of the law of probability that in 50% of all the cases of promoter action the rule must hold true even if there be no relation between atomic number and promoter action. The atomic numbers of the metals under consideration are Mn (25),

Fe (26), Cu (29)—so the rule holds in the combination Fe₂O₃-MnO₂, but does not in the case of CuO-MnO₂.

A comparison of Figs. 2 and 3 discloses the fact that while impure manganese dioxide is a much better catalyst than ferric oxide, the pure substance is slightly more than half as good but is very susceptible to promotion by ferric oxide. In Fig. 3 the fact that pure manganese dioxide and cupric oxide have about the same activity and nearly the same molecular weights would lead one to expect a 50–50 mixture of the two to give the

³ Pickles, Chem. Age (London), 8, 232 (1922).

best result. Such a mixture contains nearly twice as many molecules of manganese dioxide as of ferric oxide; and, although a molecule of ferric oxide is about four times as active as a molecule of manganese dioxide, this is balanced by the fact that the latter is more improved by a promoter than is the former.

Part of the experimental work for this paper was performed by Myron A. Snell, to whom acknowledgement is hereby made.

Summary

The fact that commercial manganese dioxide is a more effective catalyst than the c. p. material in the decomposition of potassium chlorate is ascribed to the presence of 8.8% of ferric oxide in the former.

Experiments with mixtures of these two oxides confirm this view and show that each oxide is a promoter for the other.

The action of cupric oxide and manganese dioxide as mutual promoters is also demonstrated.

A STUDY OF AMINO AND OXIMO DERIVATIVES OF THYMOQUINONE¹

By Ralph M. Hixon²

RECEIVED NOVEMBER 20, 1922

The study of the reaction of the amines with the quinones dates from the time of Hofmann's report³ of the isolation of a compound of the composition $C_6H_2O_2.N(C_6H_5)H$ from the reaction mixture of aniline and benzo-quinone. Some years later, the reaction was studied thoroughly by Zincke.⁴ He concluded that the amines reacted with the quinones in different ways under different conditions, giving the formulas of the following reaction products as proof of his statement.

Phenanthraquinone + methyl amine give $(C_{14}H_{18})(:N-CH_3)=0$ and $(C_{14}H_{18})(:N-CH_3)=0$ (1)

Phenanthraquinone + ammonia give (C₁₄H₁₈)(:N—H)=0 (2)

Benzoquinone + aniline give $(C_6H_2O_2)_2(NHC_6H_5)_2$ (3)

In 1881, Zincke⁵ concluded that the amines reacting with the quinones, replace a hydrogen atom of the quinone nucleus. This conclusion rested

- ¹ This communication is a portion of a thesis submitted to the University of Wisconsin in partial fulfilment of the requirements for the degree of Doctor of Philosophy in Chemistry.
 - ² Fritzsche Brothers Fellow.
 - 3 Hofmann, Jahresber., 1863, 415.
 - 4 Zincke, Ber., 12, 1641 (1879).
 - ⁵ Zincke, Ber., 14, 92 (1881).

on the synthesis of the amine derivatives by reactions of the following type.

$$\begin{array}{c} O \\ CH_3 \longrightarrow Br \\ Br \longrightarrow C_3H_7 \end{array} + HNHCH_3 \longrightarrow \begin{array}{c} CH_3 \longrightarrow NHCH_3 + HBr \\ C_3H_7 \longrightarrow C_3H_7 \end{array}$$
 (4)

It should be noted that in drawing this conclusion, Zincke ignored the analyses of the phenanthraquinone derivatives which he had previously reported.

As a result of Zincke's work, the reactions of the amines with the quinones have been written as though direct union took place at the positions of the hydrogen atoms in the quinone nucleus. In 1901, Hofmann⁶ reported the following reaction for dibromo-thymoquinone with aniline.

$$\begin{array}{c} \text{Br} \longrightarrow \text{CH}_3 \\ \text{C}_3\text{H}_7 \longrightarrow \text{Br} \end{array} + \text{HNHC}_6\text{H}_5 \longrightarrow \begin{array}{c} \text{Br} \longrightarrow \text{NHC}_6\text{H}_3 + \text{CH}_4 \\ \text{C}_3\text{H}_7 \longrightarrow \text{Br} \end{array} \tag{5}$$

It will be seen that the reaction differs markedly from Reaction 4.

Considerable light is thrown upon the anomalous behavior of the quinones when their structure is compared to that of similar aliphatic compounds. The carbonyl group adds ammonia (or ammonia derivatives) to give addition compounds of the type = C(OH)NR₂; reference may be made to the aldehyde ammonia⁷ and to the stable compound described by Nef.⁸ Unsaturated aliphatic and aromatic compounds containing a carbonyl group may also add ammonia derivatives at the double bond⁹ as in the cases of the action of ammonia on certain unsaturated acids and the action of hydroxylamine on carvone.

In analogy to these reactions of ammonia derivatives with less complex compounds, the following reactions may be expected with the quinone nucleus under different conditions:¹⁰

- ⁶ Hofmann, Ber., 34, 1559 (1901). Böters, Ber., 35, 1502 (1902).
- ⁷ Richter-Smith, "Organic Chemistry," Blakiston, 8th ed., 1900, pp. 205-6.
- ⁸ Nef, Ann., 270, 267 (1922).
- ⁹ Weyl, "Methoden der organischen Chemie," Vol. I, p. 642.
- No The intermediate compound has been written in this form to show its analogy with the ammonia salts, such as NH₃.HCl. The existence of such union follows at once from consideration of the quinone structure in terms of the "Octet Theory." The cubical structure of Lewis and Langmuir has been avoided to prevent undue confusion, although their conclusions have played an important part in this study of thymoquinone.

The action of hydroxylamine upon the quinones and ammonia upon phenanthraquinone fall under type "a," but for most of the other reactions either "a" or "c" seems equally possible. The final product undoubtedly depends upon the basicity of the nitrogen derivative as well as upon the characteristics induced in the quinone nucleus by modifying its structure.

Thus dibromo-thymoquinone splits off hydrogen bromide in the expected way in the presence of the relatively strong base, monomethyl amine, but unexpectedly splits off methane with the weak base, aniline (see Reactions 4 and 5). McPherson and Dubois¹¹ have pointed out that the ketonic characteristics of the quinone carbonyl groups decrease with the introduction of negative groups in the quinone nucleus. The reaction of hydroxylamine with monohydroxy-thymoquinone to give monohydroxyamino-thymoquinone¹² instead of an oxime as was to be expected is to be explained by this decreased carbonyl characteristic and by the greater lability of the hydrogen induced by the presence of negative groups. Likewise, the action of hydroxylamine with dihydroxy-benzoquinone and monochloro-dihydroxy-benzoquinone reported by Kehrmann¹³ shows only one carbonyl group reacting to give an oxime, while one hydroxy group is replaced by an amino group in analogy to these reactions. Phenanthraquinone reacts with ammonia to give an imide,⁴ which would indicate an

¹¹ McPherson and Dubois, This Journal, 30, 816 (1908).

¹² Kowalski, Ber., 25, 1658 (1892).

¹³ Kehrmann and Tiesler, J. prakt. Chem., 41, 87 (1890).

intermediate addition compound similar to the aldehyde ammonia; in this connection it should be pointed out that the structure of phenanthraquinone is quite different from that of the true quinones, since the double bonds in the former are a part of neighboring phenyl rings and so are not capable of the rearrangements characteristic of the other quinones.

An intermediate addition compound similar to the ammonium salts in structure is indicated in Reaction 6; the possible existence of such compounds follows when the structure of the quinone is expressed according to the octet theories of Lewis and of Langmuir.¹⁰ Colorless crystalline addition compounds between amines and quinones have been frequently observed and various structures assigned to them; a summary of this work is given by Meyer and by Suide.¹⁴ The original work of Hebebrand¹⁵ on these compounds indicates that they have an ammonium structure.

It seemed possible that similar addition compounds would be formed by tertiary amines with the quinones which would be less apt to rearrange and, therefore, be more satisfactory for study. Examination of the literature gave but one confirmation of the existence of such compounds. Jackson and Clark¹⁶ state that dimethyl-aniline yielded colored addition products with all the quinones at their disposal. Most of these compounds were unstable but analyses were obtained for several which indicated union in equimolecular proportions.

Action of Dimethyl-aniline on Thymoquinone.—A few qualitative tests confirmed the statement of Jackson and Clark. It was found that thymoquinone dissolved in dimethyl-aniline with considerable absorption of heat; 8.2 g. of thymoquinone dissolved in two equivalents of dimethyl-aniline (12.1 g.) produced a drop in temperature from 23° to 10°, no precautions being taken to prevent the absorption of heat from external sources.

Although considerable time has been devoted to the study of this reaction, the conclusions are not definite. In the absence of solvents and oxidizing agents, including air, the mixture remains unchanged for months but in the presence of a solvent or of an oxidizing agent a purple tar is produced which is soluble in acids but decomposed by aqueous alkaline solutions. Saponification of the purple tar with 50% sulfuric acid yielded some dihydroxy-thymoquinone and the merest trace of monohydroxy-thymoquinone, which would seem to indicate that actual condensation had taken place just as between the primary and secondary amines and the quinones. The conclusion is not fully justified, however, until such a condensation product has been actually isolated. After the hydrolysis, small quantities of an intermediate crystalline compound (m. p. about

¹⁴ Suide, Ann., 416, 113 (1918).

¹⁵ Hebehrand, Ber., 15, 1973 (1882).

¹⁶ Jackson and Clark, Am. Chem. J., 34, 441 (1905).

 $140\,^{\circ}$ with decomposition) were isolated but could not be obtained pure enough for analysis. 17

From the structural standpoint of the octet theory, these addition reactions are analogous to the addition of tertiary amines with carboxyl chlorides¹⁸ and also to the addition reaction between the carbonyl group and phosphorus trichloride recently studied by Conant.¹⁹

Preparation of Nitroso-thymol and Nitroso-carvacrol.—The nitroso-thymol and nitroso-carvacrol were prepared in amounts of 200 g. each.²⁰ Directions for purifying these large quantities of crude materials follow.

- 1. Draw off as much as possible of the mother liquor with the aid of a suction pump, and wash the compound well with water. If the compound is dried without further purification, either in air or in a vacuum, it will become discolored in the course of a few days, oxides of nitrogen being slowly evolved in the decomposition. Preparations containing only a small amount of impurities show this decomposition.
- 2. Transfer the wet nitroso compound from the funnel to a large beaker and wash it twice with sufficient alcohol to form a thick paste; then remove as much of the alcohol as possible by means of a filter pump. An excess of alcohol should be avoided as the compound is quite soluble.
- 3. Remove the alcohol by washing the solid with a small amount of ether and dry the compound in a vacuum desiccator as rapidly as possible.
- 4. Beautiful crystals of nitroso-carvacrol can be obtained by crystallizing the dry compound from hot benzene. Benzene is also the best solvent for recrystallizing the nitroso-thymol, but the crystals of the latter are not so well formed nor as stable as the nitroso-carvacrol.
- 5. In case it is desired to separate the nitroso compounds from quantities of red, oily decomposition products which are frequently encountered in working with these compounds, benzene or a benzene-ether mixture will be found more efficient than either ether or alcohol as recommended in the literature.

Preparation of the Benzoyl Derivatives of Nitroso-thymol and Nitroso-carvacrol.—These compounds have been previously prepared and studied in connection with the structure of the nitroso compounds.

In this study, they were prepared in amounts of 90 g. each, according to the Schotten-Baumann method as outlined by Sherk.²¹ Sherk reports that alcoholysis takes place upon recrystallizing these compounds from alcohol. This can be avoided to a large extent by pulverizing the crude reaction product and thoroughly washing it with a dilute solution of sodium hydroxide and then with water. The compound can be recrystallized from hot alcohol as Sherk describes but a better product can be obtained by recrystallizing the dry compound from hot heptane after removing the water by washing it with alcohol and ether and then drying it in a vacuum. A yield of 92% is easily attainable by this method.

¹⁷ A similar compound has been obtained by Nellie Wakeman in this Laboratory from the hydrolysis of the reaction mixture of piperidine with thymoquinone (unpublished results).

²¹ Sherk, Am. J. Pharm., 93, 207 (1920).

Action of Methylamine upon the Benzoyl-nitroso-phenols.—The study of this reaction was begun at this Laboratory by Miss Julia Whelan.²² It was hoped that amino derivatives might be obtained analogous to the amino-quinones. She reported that a white crystalline compound (m. p., 128–130° with decomposition) was produced by the action of a 33% aqueous solution of methylamine upon a heptane solution of benzoyl-nitroso-thymol. The reaction was also repeated using methylamine hydrochloride with an equivalent of powdered sodium carbonate in dry heptane. Only small quantities of the feathery white crystals could be isolated. The crystals were contaminated with small quantities of darkly colored tar which was believed to be an amino derivative.

In order to push the reaction to completion and also to avoid the presence of water, dry methylamine gas was passed into a solution of benzoyl-nitroso-thymol in dry heptane at 100°. White feathery crystals identical with those obtained by Miss Whelan separated almost immediately. It was almost impossible to free these crystals by fractional crystallization from the tar which was also formed in the reaction. By pressing them on a porous plate and then recrystallizing them from a mixture of ether and heptane, chloroform, and benzene, in the order named, the compound was purified and identified as nitrosothymol. The reaction has also been carried out with benzoyl-nitroso-carvacrol and found to yield the nitroso-carvacrol. Yields of 75% of the calculated nitroso-phenol content have been recovered and, since the tar still contained considerable quantities of the compound, there is no doubt that "hydrolysis" is the principal reaction taking place. It has not been possible to identify the other constituents of the tar.

It is to be noted that the reaction takes place in a water-free medium and cannot be considered as "hydrolysis of an ester" as the term is ordinarily used. If the methylamine is considered to add to the carbonyl oxygen of the benzoyl group in analogy with the previous reactions, a simple explanation of the reaction is possible.

$$O = \begin{array}{c} O \\ = N - O \\ C_{0}H_{5} \end{array} \xrightarrow{H_{2}N - CH_{3}} \left(O = \begin{array}{c} H \mid O \\ C_{0}H_{5} \end{array} \right) \xrightarrow{H} CH_{3}$$

$$O = \begin{array}{c} O \mid C - N \\ C_{0}H_{5} \end{array} \xrightarrow{H} CH_{3} \xrightarrow{C} CH_$$

It should be indicated that the imide group I

$$O = \bigvee_{\mathbf{I}} = \mathbf{N} - \bigvee_{\mathbf{II}} = \mathbf{N} O - \bigvee_{\mathbf{II}}$$

²² Whelan, unpublished results from this Laboratory, 1921.

is an extremely strong base, so that rupture at this bond is not to be expected, while the nitroso-phenol group II is only weakly acid and together with the phenyl group might be expected to impose conditions on the carbonyl group analogous to those of the aliphatic aldehydes or ketones having negative groups (such as double bonds) adjacent to the carbonyl group.

Nitric Acid Addition Products of Benzoyl-nitroso-thymol and Benzoyl-nitroso-carvacrol.—Benzoyl-nitroso-thymol and benzoyl-nitroso-carvacrol form unstable salt-like addition products with nitric acid. When the benzoyl derivatives are dropped into concd. nitric acid, these compounds separate; they are then collected on a filter and dried with filter paper.

The addition product of benzoyl-nitroso-thymol and nitric acid melts at 53° and contains at least 3 molecules of nitric acid. In view of the numerous possibilities the formula can be written only as $C_{17}H_{17}NO_2.3HNO_2$.

The analogous addition product of benzoyl-nitroso-carvacrol melts at 65° and contains 2 molecules of nitric acid per molecule of benzoyl-nitroso-carvacrol, and the formula may therefore be written as $(C_{17}H_{17}NO_2).2HNO_3$.

Both of these nitric acid addition products decompose slowly in air, and instantaneously when thrown into water. They are apparently analogous to the unstable nitric acid addition product of fluorenone, $(C_6H_4)_2C=O$ -HNO₃, described by Schmidt and Bauer²³ and also to the addition compound of phenanthraquinone $(C_6H_4)_2(C=O)_2$.HNO₃ described by Kehrmann and Mattison.²⁴ Such products are of interest in connection with the study of the action of nitric acid on thymoquinone²⁵ and also the action of acids in general on the quinones.

Preparation of Thymoquinone-dioxime.—Goldschmidt and Schmid²⁶ were unable to prepare a dioxime of thymoquinone. In 1890, Kehrmann and Messinger²⁷ found that an excess of hydroxylamine hydrochloride acting upon a saturated alcoholic solution of nitroso-thymol under a reflux condenser gave small yields of thymoquinone-dioxime. The yield could be increased slightly by adding sodium carbonate at frequent intervals but never in sufficient quantities to neutralize all of the hydrogen chloride formed in the reaction. This reaction has been repeated several times in this Laboratory but the yield of the dioxime was never greater than 6–10%.

There appears to be no statement in the literature regarding the action of hydroxylamine upon nitroso-carvacrol. Following the directions of Kehrmann and Messinger for the reaction with nitroso-thymol, yields of the dioxime were obtained varying between 60 and 70%. It is very

- 23 Schmidt and Bauer, Ber., 38, 3758 (1905).
- ²⁴ Kehrmann and Mattison, Ber., 35, 343 (1902).
- ²⁵ Hixon, "Action of Nitric Acid on Thymoquinone," unpublished results.
- 26 Goldschmidt and Schmid, Ber., 17, 2060 (1884).
- ²⁷ Kehrmann and Messinger, Ber., 23, 3557 (1890).

interesting to note that the characteristics of the reaction of thymoquinone with hydroxylamine generally ascribed to "steric hindrance," hold also for the reaction of the monoximes with hydroxylamine.

Thymoquinone-dioxime Dibenzoate.—The dibenzoic ester of thymoquinone-dioxime was prepared by the Schotten-Baumann reaction.

The compound is insoluble in alcohol and ether but crystallizes from hot benzene (5 g. requires about 75 cc. of benzene) as colorless needles. The ester is rapidly saponified by alcoholic sodium hydroxide in the cold. The compound discolors when heated to 170° and melts at 199–200°.

The analysis agrees with the values calculated for the thymoquinone-dioxime dibenzoate.

Analyses. Subs., 0.2000: CO₂, 0.5247; H_2O , 0.0910. Calc. for $C_{24}H_{22}O_4N_2$: C, 71.6; H, 5.4. Found: C, 71.55; H, 5.15.

In view of the fact that the production of the ester from the dioxime takes place practically quantitatively, this compound is of value for purposes of identification.

Summary

- 1. It is pointed out that the quinones, being unsaturated cyclic ketones, should be expected to add ammonia (or ammonia derivatives): (a) at the carbonyl group, in analogy with the aldehyde ammonia compounds; (b) at the double bond, in analogy with some of the unsaturated aliphatic acids. Evidence is presented which indicates that both types of reactions take place with the quinones.
- 2. Evidence is presented that the intermediate addition compounds between amines and quinones have structures analogous to that of ammonia salts. Tertiary amines would be expected to form similar addition compounds with the quinones which would not rearrange. Jackson and Clark have reported that dimethyl-aniline yielded colored addition products with all the quinones at their disposal.
- 3. The reaction between dimethyl-aniline and thymoquinone has been studied. An addition compound appears to be formed which rearranges to a purplish tar. This latter reaction product is difficultly hydrolyzed by 50% sulfuric acid, both mono- and dihydroxy-thymoquinone being obtained. This evidence is indicative (but not conclusive) that tertiary amines may react with quinones just as do primary and secondary amines.
- 4. Details are given for the preparation of nitroso-thymol and nitroso-carvacrol in the crystalline state in quantity from the crude amorphous compounds. The crystalline compounds discolor very slowly in direct sunlight, whereas the crude products are quite unstable.
- 5. Benzoyl "nitroso-thymol" and benzoyl "nitroso-carvacrol" are decomposed by dry methylamine in dry heptane. This reaction cannot be considered as "hydrolysis of an ester" as the term is ordinarily applied.

The reaction is easily explained by the assumption of an intermediate addition compound similar to the aldehyde ammonias.

- 6. Unstable nitric acid addition products of benzoyl "nitroso-thymol" and benzoyl "nitroso-carvacrol" are described for the first time.
- 7. Thymoquinone-dioxime can be prepared more conveniently from nitroso-carvacrol than from nitroso-thymol; the former yielding 70% of the calculated quantity of dioxime whereas the latter yields only 10%.
- 8. The dibenzoic ester of thymoquinone-dioxime is described for the first time. The compound is of value for the identification of the dioxime.

 AMES. IOWA

THE SALTS OF MALEIC, FUMARIC AND INACTIVE MALIC ACIDS

By John Morris Weiss and Charles Raymond Downs Received March 27, 1923

In various investigations which had for their purpose the development of analytical methods for mixtures of maleic, fumaric and malic acids, a number of salts of these three acids were prepared and studied. The results are admittedly incomplete and in certain instances the compounds deserve further study. We are presenting here the results obtained, regretting that we did not have the time to study all the compounds thoroughly but hoping that others will do so. We wish to express our thanks to Dr. G. C. Bailey, Dr. H. E. Williams and Dr. Wolesensky for the careful work which they carried on under our direction in preparing and determining the formulas and solubilities of a number of the compounds described, and to Mr. E. C. Buck for the very careful preliminary search of the literature which he made in this connection.

Ammonium Salts

Analysis.—These salts were analyzed by distilling the material with an excess of standard sodium hydroxide solution and collecting the distillate in an excess of standard sulfuric acid. The distillate, titrated back with methyl orange as indicator, gave the ammonia content; and the flask residue, titrated back with phenolphthalein as indicator, gave the acid radical content.

Ammonium Fumarate.—The product was best prepared by treating fumaric acid suspended in water with concd. ammonium hydroxide in slight excess of the calculated amount, concentrating in a vacuum at not over 60°, adding a little ammonium hydroxide to make up for losses in concentration and allowing the substance to crystallize. The crystals were filtered and washed with alcohol.

Analyses. Calc. for $(NH_4)_2C_4H_2O_4$: NH_3 , 22.67; $C_4H_4O_4$, 77.33. Found: NH_3 , 22.55; $C_4H_4O_4$, 77.40.

The aqueous solution of the salt is stable at 60° but when boiled it loses ammonia; 4.5506 g. of salt was dissolved in 200 cc. of water and the solution distilled, the distillate

¹ Keiser and McMaster, Am. Chem. J., 49, 84 (1913).

being collected in standard acid. In 50 minutes 0.08148 g. of ammonia distilled with 150 cc. water, representing 7.9% decomposition. On the addition and distillation of 150 cc. more water, 0.03933 g. of ammonia was volatilized (3.8%). The final limit of this decomposition or the product formed was not determined.

Ammonium Acid Fumarate.²—Fumaric acid was neutralized by two molecules of ammonium hydroxide with litmus as indicator and a second portion of fumaric acid equal to the first added. The mixture was fractionally crystallized into two lots of crystals, each equivalent to slightly more than $^1/_3$ of the whole, the balance in the mother liquor being discarded.

Analyses. Calc. for NH₄C₄H₃O₄: NH₃, 12.78; C₄H₄O₄, 87.21. Found: Fraction 1: NH₃, 11.70; C₄H₄O₄, 87.70; Fraction 2: NH₃, 12.70; C₄H₄O₆, 87.40.

Ammonium Maleate. 1.3—We were not able to obtain crystalline material by the same method as that used for ammonium fumarate. Under ordinary pressure, the solution does not lose ammonia by evaporation. Only a thick sirup results which cannot be crystallized. When the solution is evaporated in a vacuum, the solid obtained is ammonium acid maleate. This salt deserves attention by future investigators.

Ammonium Acid Maleate.3—This salt was obtained by the same method as described under the corresponding fumarate.

Analyses. Calc. for $NH_4C_4H_3O_4$: NH_3 , 12.78; $C_4H_4O_4$, 87.21. Found: NH_3 , 12.72; $C_4H_4O_4$, 87.16.

Sodium Salts

The sodium acid maleate^{3,4}, sodium maleate^{3,4}, sodium acid fumarate⁵ and sodium fumarate^{2,5,6} were prepared by mixing the acids with the proper amounts of sodium hydroxide in water solution, allowing the salt to crystallize and drying it at room temperature.

The data on water of crystallization as given in the literature were confirmed by ignition to sodium carbonate. In the case of the sodium acid fumarate, where there are no data, we found the crystalline material to be anhydrous.

Barium and Strontium Salts

Barium acid maleate,³ barium maleate,³.7,8, barium fumarate² and barium i-malate³,¹0,¹¹ have been described. We did not isolate these but observed that a heavy white precipitate of slight solubility was obtained when a 10% solution of barium chloride was added to a 10% solution of either sodium maleate or fumarate. With sodium i-malate only a slight precipitate was formed.

- 11 Duboux and Cuttat, Helvetica Chim. Acta, 4, 735 (1921).

Strontium acid maleate and strontium maleate³ and strontium i-malate¹¹ have been prepared.

Strontium fumarate² has been described as containing three molecules of water of crystallization.

We prepared this salt by mixing strontium nitrate and sodium fumarate in water solution in equimolecular proportions, filtering off the precipitate and drying at 100° at which temperature it was anhydrous.

Analyses. Calc. for SrC₄H₂O₄: Sr, 43.45; H, 0.99. Found: Sr, 43.25; H, 1.13.

Calcium Salts

The compositions were determined by igniting the salts to calcium oxide.

Calcium Acid Maleate³ was prepared and found to correspond with the formula as given for 5 molecules of water of crystallization. With the neutral salt³ the same coincidence was observed, this salt containing one molecule of water.

Analysis. Calc. for CaC4H2O4.H2O: Ca, 23.25. Found: 23.28.

Calcium Fumarate^{2,7,12} was prepared by precipitating a sodium fumarate solution with calcium chloride, and filtering, washing and air-drying the product. Our material corresponded to the trihydrate described in the literature.

Analyses. Calc. for $CaC_4H_2O_4.3H_2O$: Ca, 19.23; H, 3.84. Found: Ca, 19.47; H, 4.01.

Calcium Acid Fumarate is not described in the literature. When a solution of sodium acid fumarate was mixed with a molecular equivalent of calcium chloride and evaporated, crystals were obtained which were separated and air-dried.

Analysis. Calc. for CaC₈H₆O₈.2H₂O: Ca, 13.06. Found: 13.22.

Calcium Acid i-Malate¹³ is stated to contain one molecule of water of crystallization. Our preparation was made by heating 52.8 g. of i-malic acid with 20 g. of calcium carbonate, filtering the solution, allowing it to crystallize, and separating and air-drying the crystals; yield, 64 g. The substance was found to be the anhydrous salt.

Analysis. Calc. for CaC₈H₁₀O₁₀: Ca, 13.06. Found: 12.85.

Magnesium Salts

Magnesium acid maleate, magnesium maleate, $^{3\cdot14}$ magnesium fumarate² and magnesium i-malate¹¹ have been described. These salts were not prepared but note was made that none of the three acids is precipitated from its sodium salt solutions (10%) by soluble magnesium compounds. In an attempt to produce the i-malate, magnesium oxide was dissolved in i-malic acid. On concentrating the filtered solution a sirup was obtained which did not crystallize but solidified on standing to a hard white mass.

Cobalt Salts

Cohalt Maleate is not described in the literature.

Cobalt was precipitated as carbonate from a solution of its nitrate and the latter filtered, washed and suspended in water. An equivalent quantity of maleic acid was added and the solution filtered and evaporated.

¹² Carius, Ann., 142, 129 (1867).

¹³ Bremer, Ber., 8, 863 (1875).

¹⁴ Walden, Z. physik. Chem., 1, 529 (1887).

Analysis. Calc. for CoC4H2O4.11H2O: Co, 15.90. Found: 15 15.80.

Cobalt Fumarate² is stated to correspond to the formula CoC₄H₂O₄.3H₂O; this we were unable to confirm. Using concentrated solutions of cobalt nitrate and sodium fumarate, a copious, crystalline, pink precipitate was obtained. This was washed and air-dried.

Analyses. Calc. for CoC₄H₂O₄.4H₂O: C, 19.59; H, 4.08; Co, 24.07. Found: C, 20.36; H, 3.86; Co, 23.93.

When the pink compound was dried at 100° it became somewhat bluish from loss of water.

Analysis. Calc. for CoC₄H₂O₄.2H₂O: Co, 28.23. Found: 28.62.

Cobalt *i*-Malate.—This is not described in the literature. It was prepared by treating cobalt carbonate suspended in water with the calculated amount of *i*-malic acid and evaporating the mixture to dryness at 100° . The formula seems to be that of a trihydrate.

Analyses. Calc. for CoC₄H₄O₅.3H₂O: C, 4.08; H, 24.07; Co, 19.59. Found: C, 4.15; H, 23.40; Co, 19.28.

Nickel Salts

The nickel was determined by digesting a sample with concentrated ammonium hydroxide, adding water, a small amount of sodium iodide (0.02–0.05 g.), a few drops of standard silver nitrate solution and an excess of standard sodium cyanide solution. The excess was titrated back with silver nitrate to a slight permanent precipitate.

Nickel Fumarate² is stated to contain 4 molecules of water of crystallization. The salt was prepared by mixing dilute solutions of nickel nitrate and sodium fumarate and concentrating until a green crystalline precipitate was formed, and removing soluble materials by repeated boiling with water.

Analyses. Calc. for NiC₄H₂O₄.4H₂O: Ni, 24.08; calc. for NiC₄H₂O₄.5H₂O: 22.43. Found: 23.42.

If the precipitation of the nickel fumarate is carried on in concentrated solution, a different product seems to be formed.

Analyses. Calc. for NiC₄H₂O₄.5H₂O: C, 18.27; H, 4.56; Ni, 22.43. Found: C, 18.44; H, 4.06; Ni, 22.30.

Nickel Maleate³ resembles the fumarate in general properties but appears to be more soluble. This compound was not analyzed.

Nickel i-Malate is not described in the literature. It is extremely soluble in water and, therefore, cannot be precipitated. If nickel carbonate is dissolved in malic acid a green solution is obtained which on concentration forms a jelly. On long standing at room temperature, the sample lost water and crystals began to appear. This compound was isolated but not analyzed.

Manganous Salts

Manganous Acid Maleate.—This compound has not been previously described; 69.6 g. of maleic acid was dissolved in the minimum amount of water at 30° and to this was added 34.6 g. of manganese carbonate. A solid separated which was dissolved by warming it. As the solution was cooled in ice water, a granular pink precipitate was formed which was filtered, washed, recrystallized from water and dried at room temperature; yield, 32.5 g.

¹⁵ Cobalt was determined by ignition to cobaltous cobaltic oxide, Co₂O₄.

Analyses. Calc. for $MnC_8H_6O_8.4^1/_2H_2O$: C, 25.60; H, 4.20; Mn, 15.02. Found: C, 25.37; H, 3.91; Mn, 15.19.

From examination of the crystals microscopically, it appears that the salt is stable in the air and in a vacuum over sulfuric acid.

Manganous Maleate has not been previously described. It was prepared in the same manner as the acid salt except that twice as much manganese carbonate was used. It appears to be stable at 100°. In dil. water solution it decomposes with the formation of manganese dioxide.

Analyses. Calc. for $MnC_4H_2O_4.3H_2O$: C, 21.53; H, 3.58; Mn, 24.64. Found: C, 21.01; H, 3.31; Mn, 24.48.

Manganous Fumarate² has been stated to have the formula $\rm MnC_4H_2O_4.3H_2O$. Our results did not confirm this. To 11.55 g, of manganese carbonate we added 11.6 g, of fumaric acid. The slight excess of carbonate was filtered off and the filtrate evaporated until a precipitate appeared, at first flocculent and then granular. This was filtered off and dried at room temperature.

Analyses. Calc. for MnC₄H₂O₄: C, 28.41; H, 1.18; Mn, 32.54. Found: C, 27.55; H, 1.42; Mn, 32.02.

Zinc Salts

Zinc was determined by ignition to zinc oxide.

Zinc Acid Maleate16 was not prepared.

Zinc Maleate³ was made by quickly mixing a saturated maleic acid solution with zinc carbonate as a paste in a mortar and filtering before the zinc maleate separated. Zinc maleate formed as a white, granular precipitate which was washed and dried at room temperature.

Analyses. Calc. for $ZnC_4H_2O_4.2H_2O$: C, 22.80; H, 2.78; Zn, 30.42. Found: C, 21.78; H, 2.78; Zn, 30.68.

When a solution of zinc maleate is heated, it decomposes giving a flocculent precipitate.

Zinc Fumarate² has been described in two modifications with 3 and 4 molecules of water, respectively. Our product was made by treating a suspension of fumaric acid with an excess of zinc carbonate in a mortar, filtering the mixture and evaporating the filtrate until crystallization began. Colorless crystals were obtained and dried at room temperature.

Analyses. Calc. for $ZnC_4H_2O_4.5H_2O$: C, 17.81; H, 4.45; Zn, 24.26. Found: C, 17.24; H, 4.25; Zn, 24.42.

Iron Salts

Ferric Maleate³ has been described as an indeterminate smear. On evaporation of a mixture of two molecular equivalents of ferric hydroxide and three molecular equivalents of maleic acid a dark, nearly black, amorphous mass was obtained which was dried at 100°. When analyzed this showed approximately the composition of the dihydrate.

Analyses. Calc. for $Fe_2(C_4H_2O_4)_3.2H_2O$: C, 29.4; H, 2.04; Fe, 22.88. Found: C, 27.34; H, 2.59; Fe, 22.90.

In solution this material seems to be able to hold an excess of ferric hydroxide. Ferric Fumarate² could not be prepared from ferric hydroxide and fumaric acid. Ferric *i*-Malate¹⁷ was not prepared, but considerable work was carried on with

¹⁶ Richter, Z. Chem., 11, 449 (1868).

¹⁷ Pickering, J. Chem. Soc., 103, 1358 (1914).

ferric ammonium *i*-malate. One molecular equivalent of ferric hydroxide (precipitated cold because when precipitated hot it did not dissolve properly) was mixed with a clear solution of 2 molecular equivalents of malic acid and the mixture was heated to 60°. One molecular equivalent of ammonium hydroxide was then added and the mixture heated rapidly to boiling. The work was carried on in semi-darkness as the material is light sensitive. A clear, red-brown solution resulted which was cooled rapidly in an ice-bath. It showed no ferrous iron when tested with ferricyanide solution. The solution was not stable even in the dark, as ferrous iron appeared on standing and gradually increased. When a thick solution was painted on glass and dried in a dark closet at room temperature a solid similar to ferric ammonium citrate was produced which contained no ferrous iron. When it was dried between 30° and 40° some reduction took place.

To compare the sensitivity of ferric ammonium malate and citrate, dilute solutions of each, free from ferrous iron, were placed in sunlight and tested for ferrous iron. After 5 minutes the malate showed a faint test for ferrous iron and after 10 minutes a very positive test, while the citrate was negative at 24 minutes and showed a positive test only after 39 minutes. In the dark at 100° after 5 minutes the malate showed ferrous iron, while after 20 minutes the citrate still tested negatively.

Attempts to produce ferric ammonium maleate or fumarate in the same way were unsuccessful.

Copper Salts

Copper was estimated volumetrically in acetic acid solution by means of sodium iodide and thiosulfate.

Copper Fumarate^{2,12,18} has been described both as a dihydrate and trihydrate. We obtained our material by precipitating fumaric acid with copper sulfate. The pale blue precipitate was washed and dried at 100°.

Analyses. Calc. for $CuC_4H_2O_4.2H_2O$: C, 22.47; H, 2.80; Cu, 29.78. Found: C, 21.70; H, 3.06; Cu, 29.45.

Copper Maleate^{3,18} was prepared by precipitating a solution of equimolecular equivalents of copper sulfate and maleic acid with sodium carbonate. A deep blue crystalline precipitate formed which, as stated by the previous investigators, is the monohydrate.

Analyses. Calc. for $CuC_4H_2O_4.H_2O$: C, 24.54; H, 2.04; Cu, 32.50. Found: C, 24.05; H, 2.39; Cu, 32.22.

Copper *i*-Malate has not been described. When equivalent quantities of copper carbonate and *i*-malic acid solutions are mixed and the mixture is evaporated, a hard vitreous blue mass is formed which after several weeks becomes crystalline. It contains at this stage 25.02% of copper, which indicates a trihydrate (25.49% of copper). On continued exposure, the mass becomes paler blue and shows the presence of 25.70% of copper.

Analyses. Calc. for CuC₄H₄O_{5.2}H₂O: C, 20.72; H, 3.45; Cu, 27.28. Found: C, 20.86; H, 3.16; Cu, 25.70.

This formula is quite doubtful and further work is indicated.

Cadmium Salts

Cadmium salts of maleic and fumaric acids have not been described in the literature. Cadmium was determined by igniting the salt to the oxide, CdO, in a stream of oxygen.

¹⁸ Pickering, J. Chem. Soc., 101, 174 (1912).

Cadmium Fumarate.—Prepared by precipitating sodium fumarate with cadmium chloride in concentrated solutions this forms a copious, finely divided, white precipitate. It was filtered, washed and dried at 100°.

Analyses. Calc. for $CdC_4H_2O_4$: C, 21.20; H, 0.88; Cd, 49.57. Found: C, 21.63; H, 1.18; Cd, 49.29.

Cadmium Maleate.—This was made by mixing equimolecular proportions of cadmium chloride and sodium maleate in solution and evaporating to crystallization. The salt was washed repeatedly with hot water and dried at room temperature.

Analyses. Calc. for $CdC_4H_2O_4.2H_2O$: C, 18.29; H, 2.28; Cd, 42.75. Found: C, 17.76; H, 2.27; Cd, 42.50.

The salt retains sodium chloride tenaciously and needs exhaustive washing to purify it.

Antimony Salts

No literature references were found to these salts and all attempts to form the maleate, fumarate or i-malate by dissolving antimony trioxide in the corresponding acid were unsuccessful. In the case of i-malate, some oxide is dissolved (never more than 21% of that calculated) but apparently an excess of acid is required to prevent hydrolysis so that the salt cannot be isolated. ¹⁹

Sodium Antimonyl *i*-Malate.—Attempts were made to prepare this salt by heating 40 g. of sodium hydroxide, 144 g. of antimony trioxide and 134 g. of *i*-malic acid in water solution under a reflux condenser. After 15 hours, 82.8 g. of antimony trioxide remained undissolved. This was removed, dissolved in potassium acid tartrate and reprecipitated, washed and added again to the mixture. In this way all but 31 g. of the original quantity was finally dissolved and all attempts to increase this failed. The final solution was evaporated to a thick sirup which on seeding solidified to a white, hard mass. It can be powdered, and is apparently stable and very soluble in water. The problem of these complex salts is interesting and deserves further work.

Lead Salts

Lead was determined gravimetrically as the chromate or by titrating excess of dichromate with sodium iodide and thiosulfate.

Lead Fumarate² is stated to occur as the dihydrate. When equimolar quantities of lead nitrate and sodium fumarate were mixed in aqueous solution, fine crystalline flakes were obtained which were filtered and dried at 100°.

Analyses. Calc. for $PbC_4H_2O_4$: C, 14.91; H, 0.62; Pb, 64.48. Found: C, 14.48; H, 0.88; Pb, 64.22.

Lead Maleate^{3,20} is stated to occur as the trihydrate. When we prepared it in a manner similar to that used for the fumarate, we obtained the anhydrous salt.

Analyses. Calc. for $PbC_4H_2O_4$: C, 14.91; H, 0.62; Pb, 64.47. Found: C, 14.94; H, 0.78; Pb, 64.20.

Lead i-Malate21 is the subject of varying opinion, being reported as anhydrous,

¹⁹ Henderson and Barr, J. Chem. Soc., **69**, 1451 (1896). Henderson and Prentice, *ibid.*, **67**, 1030 (1894).

²⁰ Pelouze, Ann., 11, 263 (1834).

²¹ Lloydl, Ann., 192, 80 (1878). Kekulé, Ann., 130, 1 (1864). Pasteur, Ann. chim., [3] 30, 49 (1852). Werigo and Tanatar, Ann., 174, 367 (1874).

with $1^{1}/2$ molecules water and with 3 molecules water. This salt was obtained as a white precipitate by interaction of lead nitrate and sodium *i*-malate in aqueous solution. When heated to 100° it softens to a dough-like mass. Its formula is doubtful but seems to approach the composition PbC₄H₄O₅. $^{1}/_2$ H₂O.

Analyses. Calc. for $PbC_4H_4O_5$, $^{1}/_2H_2O$: C, 13.78; H, 1.43; Pb, 59.48. Found: C, 11.91; H, 1.46; Pb, 59.42.

Silver Salts

Silver was determined as the chloride.

Silver Maleate^{3,7}.—This was formed by precipitating silver nitrate solution with sodium maleate and was obtained as a white precipitate which was dried at 100°.

Analysis. Calc. for Ag₂C₄H₂O₄: Ag, 65.42. Found: 65.44.

The compound deflagrated when heated during combustion (leaving metallic silver) and the carbon and hydrogen results are considered unreliable.

Silver Fumarate.—This compound has not been described. It was prepared in the same way as was the maleate and behaved similarly. Its silver content was 64.90%.

Solubilities

A number of the salts were tested for solubility in water. Samples were placed in 60cc. bottles with distilled water and securely stoppered. They were then held in a thermostat at the required temperature for 24 hours, 25-cc. portions of the clear solutions were withdrawn in a weighing bottle by means of a pipet with cotton filter, weighed, transferred to a platinum

dish, evaporated to dryness and heated to constant weight at 100°. With the acid salts, the amount of solute was determined by titration. The sampling of the solutions saturated at 60° and 100° was done entirely under the surface of the water in the thermostat with an apparatus described by Pawlewski.²²

The solubility results are given in Table I.

Summary

The data in the literature regarding the salts of maleic, fumaric and *i*-malic acids have been reviewed and the water of crystallization of a number of these salts determined. In some cases the work agrees with that of past observers, but in others new numbers are apparently justified. Some 11 salts, not previously described, were prepared and the water of crystallization determined in certain cases definitely.

The solubilities in water of 22 salts were determined and tabulated. In general, fumarates are less soluble than the corresponding maleates.

50 East 41st Street New York, N. Y.

THE REACTION OF CARBON DISULFIDE ON PARA-PHENYLENEDIAMINE

By C. Ernest Bolser and Elden B. Hartshorn Received March 31, 1923

In the description of a patented process¹ for making symmetrical p-diamino-diphenyl-thio-urea, the statement is made that when carbon disulfide reacts on p-phenylenediamine in alcoholic solution two compounds are formed, symmetrical p-diamino-diphenyl-thio-urea, I, and phenylenethio-urea, a compound insoluble in cold, dil. acids and all ordinary solvents. This compound was originally described by Lellmann² and given Formula II.

$$H_2N$$
 $C=S$
 H_2N
 H
 H
 H
 H
 H
 H

The description of the patented reaction is meager, and the formation by primary reaction of two substances to one of which is assigned Formula

- ²² Pawlewski, Ber., 32, 1040 (1899).
- ¹ Wm. Noetzel and Co., Ber., 24, 849 (1891).
- ² Lellmann, Ann., 221, 29 (1883). Gucci, J. Chem. Soc. Abs., 64, 588 (1893).

II is illogical. Formula II, also, is not in accord with the probable structure of most para ring compounds. This paper, then, is a contribution to the study of para ring compounds which have been the subject of several investigations including those of von Braun,³ Perkin and Titley,⁴ and Adams and Wilson.⁵

In carrying out the patented reaction it was found that when the usual procedure of prolonged boiling in alcoholic solution was followed, a very small percentage of the reaction product consisted of the diamino-thiourea, I. To avoid the formation of the insoluble compound, p-amino-acetanilide was substituted for p-phenylenediamine, the intention being to mask one of the amino groups during the reaction with carbon disulfide, and to restore this group later by hydrolysis of the reaction product. The acetyl derivative of the diamino-diphenyl-thio-urea, (CH₃CO.NH.-C₆H₄NH)₂CS, formed readily, but all attempts to hydrolyze this compound resulted in its decomposition with the formation of phenylenediamine.

After several unsuccessful attempts to overcome the difficulty by the preparation of diazobenzene-p-thio-urea, and some of its derivatives, and their subsequent reduction, a more complete study of the patented reaction was made. This revealed that the yield of diamino-diphenylthio-urea could be increased by causing the reaction to proceed at a lower temperature with a reduced concentration of carbon disulfide, and the frequent removal of the reaction product by filtration. These experimental conditions indicated that success depended upon the removal by filtration of the diamino-diphenyl-thio-urea, which, due to its relatively slight solubility in alcohol at the lower temperature, crystallized from the solution when the proper concentration was attained. This in turn suggested that the insoluble product was not the result of primary reaction of carbon disulfide on phenylenediamine, but was due rather to secondary reaction, and that its formation would be prevented in proportion to the completeness of the removal of the primary product, I.

To accomplish this result, water in which diamino-diphenyl-thio-urea is much less soluble was substituted for alcohol as a solvent, and a special apparatus was devised to keep the temperature as near the boiling point of carbon disulfide as possible, and the concentration of the latter low. This procedure resulted in suppressing the formation of the insoluble material almost entirely. The next step was obviously to bring diamino-diphenyl-thio-urea into reaction with carbon disulfide in alcoholic solution. As expected, an insoluble compound was formed in approximately the amount demanded by the only logical formulation of the reaction, namely, $(H_2NC_6H_4NH)_2CS + CS_2 = SC(HNC_6H_4NH)_2CS + H_2S$.

³ von Braun, Ber., 45, 1274, 2512 (1912), and later articles.

⁴ Perkin and Titley, J. Chem. Soc., 122, 1562 (1922).

⁵ Adams and Wilson, This Journal, 45, 528 (1923).

Final proof that the reaction of carbon disulfide on phenylenediamine proceeds in two stages would, of course, demand that the identity of the insoluble compound formed directly from phenylenediamine with that formed from diamino-diphenyl-thio-urea be established. By neither reaction was it possible to obtain a pure product. This is apparently due to occlusion of impurities from which the product, on account of its insolubility, cannot be freed by crystallization. Both products decompose above 285°. When heated with strong acids, they dissolve with the formation of phenylenediamine. Fortunately, they are decomposed, although extremely slowly, by boiling acetic anhydride with the formation of pphenylene-diisothiocyanate, SCNC₆H₄NCS. This substance was obtained in small quantity, and was identified by its crystal form, its melting point (130°) and by the fact that a dithio-urethane of the proper melting point (197°) and crystal form was obtained from it. Not only does this reaction prove that the compounds in question are identical, but it furnishes further proof of their constitution. The formula of the substance must be

and the reaction formulated as follows: $SC(HNC_6H_4NH)_2CS + (CH_3CO)_2O = SCNC_6H_4NCS + (CH_3CONH)_2C_6H_4 + 2CH_3COOH$; for with Formula II the dimustard oil could not be formed, but should give the acetyl derivative of *p*-aminophenyl-isothiocyanate. Since this acetyl derivative is unknown, we prepared it. It crystallizes in needles melting at 195°. We were unable to discover any of it in the reaction product.

Complex thio-ureas of a higher molecular weight than that of p-diphenylene-dithio-urea were formed only by the reaction of carbon disulfide on diamino-thio-ureas having a higher molecular weight than p-diamino-diphenyl-thio-urea, I. Theoretically, such compounds might form. The homogeneity of the diamino-thio-urea formed, as shown by its crystal form, constant melting point after repeated crystallizations, and the analysis of its sulfate, seems to preclude this possibility.

In the various attempts to hydrolyze acetyl-aminophenyl-isothiocyanate referred to above, small amounts of a substance insoluble in hydrochloric acid had been obtained which, in the light of facts already discussed, led us to believe that p-aminophenyl-isothiocyanate had been formed, and that two molecules of this had then reacted to form p-diphenylene-

dithio-urea, III, whose constitution has just been established. However, it would seem logical that if the simple thio-urea, II, had any tendency to form under any conditions it would do so here where an intramolecular change alone is involved. It seemed highly desirable, therefore, to find some reaction by which p-aminophenyl-mustard oil would be formed and not further decomposed, in order that its behavior might be studied. Now, when diamino-diphenyl-thio-urea is boiled with glacial acetic acid a white insoluble powder results which yields phenylene-dimustard oil on treatment with acetic anhydride and is, therefore, p-diphenylenedithio-urea. The amount formed is approximately that demanded by the equation: $2(H_2NC_6H_4NH)_2CS + 4CH_3COOH = SC(HNC_6H_4NH)_2$ $CS + 2C_6H_4(NH_2)_2$. 2CH₃COOH. When the reaction mixture is diluted with water and filtered, the mother liquor deposits slowly an additional quantity of the same substance. When this mother liquor is rendered alkaline an immediate precipitate of the same substance results. These facts show clearly that the p-aminophenyl-mustard oil is first formed but that even in acetic acid solution the major portion condenses to form diphenylene-dithio-urea. They show further that the free base cannot exist, in solution at least, but that it immediately forms the complex thio-urea.

To bring out this point still more conclusively we prepared azobenzene p-isothiocyanate by the reaction of thiophosgene on p-amino-azobenzene and reduced this compound in acetic acid solution with stannous chloride and hydrochloric acid. Under these experimental conditions, lower temperature and presence of hydrochloric acid, the mustard oil formed does not immediately form the thio-urea, as was the case at the boiling point of acetic acid, but as soon as the clear acid solution was made sufficiently alkaline to dissolve the tin hydroxides and free the base, the insoluble high-melting diphenylene-dithio-urea appeared. Here again, as under the other conditions cited, the more complex rather than the simpler compound forms.

The simpler compound is supposed to have been obtained² by heating phenylene-diphenyl-dithio-urea, the addition product of two molecules of aniline and one of phenylene-diisothiocyanate, to high temperature. It is well known that under these conditions intermolecular changes readily take place. In the light of these facts, the demonstrated stability of the dimolecular compound and its tendency to form, where the formation of the simpler substance might be expected, throws a reasonable doubt on the existence of the latter compound.

We are now extending this method of investigation to other diamines, especially to o- and m-phenylenediamine and to benzidine.

Experimental Part

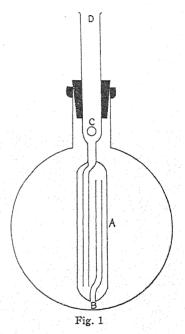

Reaction of Carbon Disulfide on p-Phenylenediamine in Alcoholic Solution.— Ten g. of phenylenediamine was dissolved in 250 cc. of alcohol and boiled on a steam-bath with an excess of carbon disulfide for 10 hours. The reaction mixture was filtered and the residue extracted with cold, dil. hydrochloric acid. By making the extract alkaline, $0.45\,\mathrm{g}$. of diamino-diphenyl-thio-urea was obtained. The insoluble residue was boiled with alcohol, then with water, and finally dried; yield, about 10 g. In a melting-point tube the substance commences to darken at about 200° and rapid decomposition takes place above 280°.

Reaction of Carbon Disulfide with p-Phenylenediamine in Aqueous Solution.—A solution of 10 g. of phenylenediamine in 250 cc. of water was placed in a round-bottomed flask to which was fitted the apparatus shown in Fig. 1. The tube A, connected with a reflux condenser at D, contained about 5 cc. of carbon disulfide and when the flask was heated on the steam-bath to the proper temperature, the vapor of carbon disulfide escaped through Tube B into the reaction mixture. The excess of vapor entered

the condenser through the opening C and the condensed liquid was returned to Tube A. During the reaction, which was allowed to continue for 10 hours, a precipitate gradually formed. This was filtered out, washed with alcohol, and extracted with dil. hydrochloric acid at room temperature. All but a small amount (about 0.8 g.) dissolved immediately and the residue was allowed to stand in the acid overnight. The solution was then filtered from the insoluble residue and made alkaline. A voluminous crystalline, nearly white precipitate was obtained, which was crystallized from boiling water-about 2 liters were requiredfiltered and dried. The compound separates in plates melting at 194-195°; yield, 8.95 g.; calculated yield, 11.94 g. The normal sulfate was prepared by precipitation.

Analysis. Subs., 0.3025: BaSO₄, 0.1958. Calc. for $C_{13}H_{14}N_4S.H_2SO_4$: SO₃, 22.47. Found: 22.20.

Reaction of Carbon Disulfide with Diaminodiphenyl-thio-urea.—Five g. of diamino-diphenylthio-urea was dissolved in 200 cc. of alcohol and the solution boiled with a large excess of carbon disulfide under a reflux condenser for 12 hours. The

clear solution soon became clouded with a precipitate which gradually increased in amount. The separated reaction product was treated successively with cold, dil. hydrochloric acid, boiling alcohol, and boiling water, and finally dried; yield, 5.55 g.; calculated yield, 5.81 g. This compound behaved in a melting-point tube exactly like the insoluble substance described above.

Proof of the Composition of the Insoluble Substances thus Obtained.—Lots of 7 g. of each of the insoluble compounds obtained by the reactions described above were boiled in separate flasks with 15 cc. of acetic anhydride for half an hour. Apparently, very little of the substance had gone into solution, but for fear of decomposition of the reaction product, the operation was interrupted and the reaction mixture filtered into water. This was then repeated several times with each residue. The combined filtrates in each case were warmed to decompose excess of acetic anhydride and a crystalline solid

Werner, J. Chem. Soc., 59, 396 (1891).

remained. By repeated recrystallization of this solid from glacial acetic acid there was obtained from each of the insoluble substances in question approximately 0.1 g. of a white compound crystallizing in long, shiny needles; m. p., 130°. Heated on the steambath with ethyl alcohol for 8 hours, this compound yielded a white crystalline powder melting at 197°. These crystal forms and melting points identify these compounds as phenylene-diisothiocyanate and the corresponding p-thio-urethane. These substances are then identical and are diphenylene-dithio-urea, III.

Reaction of Glacial Acetic Acid on Diamino-diphenyl-thio-urea.—Three g. of diamino-diphenyl-thio-urea was heated to boiling with 15 cc. of glacial acetic acid. Complete solution took place as the mixture was warmed. At the boiling point a finely divided substance began to separate, and in two or three minutes it was so abundant that the reaction mixture was nearly white. The boiling was continued for 10 minutes, when the product was poured into water. From the finely divided white powder obtained by filtration no unchanged diamino-diphenyl-thio-urea could be obtained by extraction with dil. hydrochloric acid. This powder was boiled with alcohol, then with water, and dried; yield, 1.60 g.; calculated yield, 1.92 g. In a melting-point tube it behaved like the diphenylene-dithio-urea identified as described above.

Analysis. Subs., 0.1516: N, 25.8 cc. (22°, 754.4 mm.). Calc. for $C_{14}H_{12}N_4S_2$: N. 18.66. Found: 19.06.

By treatment with acetic anhydride, phenylene-p-diisothiocyanate was obtained from this substance, and its identity with diphenylene-dithio-urea thus further established.

p-Diacetylamino-diphenyl-thio-urea, (CH₃COHNC₆H₄NH)₂CS.—Ten g. of p-amino-acetanilide was dissolved in 400 cc. of alcohol and the solution was heated in a water-bath under a reflux condenser with an excess of carbon disulfide for about 10 hours. A white, insoluble precipitate was formed, which in the agitated mother liquor somewhat resembled long-fibered asbestos. After it was filtered, washed and dried, 10.2 g. of pure, white solid was obtained that was insoluble in all ordinary solvents; m. p., 235–237°.

This compound could not be hydrolyzed except by boiling with strong acids. Under these conditions the expected diamino-diphenyl-thio-urea decomposed with formation of phenylenediamine which was identified by Lauth's violet test.

Analysis.³ Subs., 0.1896: N, 27.90 cc. (18.8°, 736 mm.). Calc. for $C_{17}H_{18}N_4O_2S$: N, 16.3. Found: 16.4.

p-Acetylamino-phenyl-isothiocyanate, CH₃CONHC₆H₄NCS.—Ten g. of the thiourea described above was boiled in an oil-bath with 30 g. of acetic anhydride. Solution took place in about 10 minutes, whereupon 200 cc. of water was immediately added. After the mixture had cooled, the precipitated solid was crystallized from alcohol as white needles; m. p., 195–196°; yield, 4.1 g. Care had to be taken not to heat it long enough with the alcohol to cause the formation of the thio-urethane.

Analysis. Subs., 0.2285: N, 29.4 cc. over 30% KOH (21.5°, 756 mm.). Subs., 0.1916: BaSO₄, 0.2304. Calc. for $C_9H_8ON_2S$: N, 15.58; S, 16.66. Found: N, 14.53; S, 16.51.

Hydrolysis of p-Acetyl-amino-phenyl-isothiocyanate.—Two g. of this compound was suspended in 30 cc. of coned. hydrochloric acid and the mixture was heated on the water-bath. Solution took place with foaming and white plates of phenylenediamine hydrochloride separated. Upon the addition of coned. hydrochloric acid a further sepa-

⁸ This analysis was made by Mr. G. W. Anderson.

⁹ This analysis was made by Mr. F. W. Vogel.

ration took place. This precipitate (0.9 g.) was then filtered, washed, dried over potassium hydroxide and analyzed.

Analysis. Subs., 0.3012: AgCl, 0.4736. Calc. for $C_6H_{10}N_2Cl_2$: Cl, 39.18. Found: 38.90.

Azobenzene-p-isothiocyanate, $C_6H_5NNC_6H_4NCS$.—Fifteen g. of p-amino-azobenzene and the same weight of thiophosgene were heated in 400 cc. of carbon tetrachloride for 4 hours on a boiling water-bath. The solution was filtered from amino-azobenzene hydrochloride and the filtrate allowed to evaporate spontaneously. The residue was crystallized from 80% acetic acid, forming salmon-colored needles; m. p., 94–95°; yield, 8.4 g.

Analyses. Subs., 0.2003: CO₂, 0.4778; H₂O, 0.0713. Subs., 0.1556: BaSO₄, (Carius) 0.1526. Calc. for $C_{12}H_9N_3S$: C, 65.22; H, 3.79; S, 13.41. Found: C, 65.06; H, 3.98; S, 13.47.

Reduction of Azobenzene-p-isothiocyanate.—When 2 g. of this substance was dissolved in 300 cc. of glacial acetic acid and 12 g. of stannous chloride in a small quantity of hot coned. hydrochloric acid was added, the orange color of the solution almost entirely disappeared. Upon dilution and the addition of enough coned. sodium hydroxide solution to redissolve the precipitated tin hydroxides, a finely divided powder separated. This powder was insoluble in dil. hydrochloric acid and in boiling 80% acetic acid and resembled completely the diphenylene-dithio-urea obtained by other reactions described above, except for a slight greenish tinge.

Summary

- 1. The reaction of carbon disulfide on p-phenylenediamine proceeds in two stages. In the first p,p'-diamino-diphenyl-thio-urea is formed, and in the second this is changed into diphenylene-dithio-urea. There is no evidence of the formation of phenylene-thio-urea, which was thought to be a product of the primary reaction of carbon disulfide on p-phenylene-diamine.
- 2. p-Aminophenyl-isothiocyanate cannot exist in the free state in solution. It changes immediately into the complex dithio-urea. This reaction also takes place in boiling acetic acid, and slowly in dil. acetic acid at room temperature. There is no evidence of the formation of phenylene-thio-urea under these conditions.
- 3. Reasonable doubt has been thrown on the existence of phenylene-thio-urea.
- 4. These results are in agreement with the probable constitution of most para ring compounds.

THE BENZIL REARRANGEMENT. V. CANNIZZARO'S REACTION

By ARTHUR LACHMAN RECEIVED APRIL 25, 1923

In several recent papers¹ it has been shown that rearrangements of the benzil and pinacol types are essentially questions of intramolecular oxidation and reduction. The present paper deals with Cannizzaro's reaction.

Introduction

As Cannizzaro² discovered, benzaldehyde rapidly solidifies when shaken with an excess of a strong solution of sodium hydroxide. Much heat is developed. The reaction mass contains nearly equal molecular equivalents of sodium benzoate and of benzyl alcohol; little or no unchanged benzaldehyde is recovered.

 $2C_6H_5-CHO + NaOH = C_6H_5-COONa + C_6H_5-CH_2OH$ (1) This is a typical oxidation-reduction process.

A number of observers have found that if water is excluded in this reaction, benzyl benzoate is a primary product. Claisen³ added sodium methoxide to benzaldehyde, and obtained a mixture of benzyl benzoate and methyl benzoate; and he found that a small amount of sodium benzoxide was capable of converting a large quantity of benzaldehyde directly into benzyl benzoate. Kohn and Tranton⁴ heated benzaldehyde with solid sodium hydroxide, in benzene suspension, and were able to isolate some benzyl benzoate from the mixture Tischtschenko⁵ obtained esters of benzoic acid when he treated benzaldehyde with aluminum alcoholates.

Action of Aqueous Alkali on Benzaldehyde

Benzyl benzoate is formed, however, even in the presence of water, if precautions are taken to prevent its subsequent hydrolysis. These precautions involve merely avoidance of an excess of alkali, and prevention of any considerable rise in temperature. In the following table are given some of the results obtained.

In each case, 106 g. of benzaldehyde was shaken in a tightly stoppered flask, with sodium hydroxide solution. After a few minutes, when emulsification had taken place, the mixture was stood in cold water for the periods noted. To isolate benzyl benzoate, the mass was covered with ether, and sufficient cold water added, with stirring, until complete solu-

tion occurred. The ether solution was separated, filtered, evaporated and the ether distilled at atmospheric pressure until the vapor temperature reached 220°; the residue was finally distilled at 15 mm. pressure until the temperature of the vapors reached 200°. There was usually a small amount of still higher-boiling residue. From the alkaline solution, benzoic acid was precipitated and weighed. The amount of benzyl alcohol produced, and of unchanged aldehyde recovered, was not estimated. The yields varied irregularly, as must be expected on account of the uncontrolled heating at the start. When 10 N alkali is used, the emulsion is very thin, and does not thicken much as reaction proceeds; and the rate is very slow. With a concentration of $14\,N$ or over, a very thick emulsion forms rapidly, which sets to a hard cake in a short time, and must be cooled promptly to prevent complete hydrolysis of the ester.

The benzyl benzoate obtained above is not entirely pure. 1.40 g., boiled with dil. sodium hydroxide, used up 5.9 cc. of N solution, gave 0.72 g. of benzoic acid, melting at 121.5°; ester content, 89%. A number of samples, combined and carefully refractioned at 5 mm., gave considerable dibenzyl ether, boiling at 130–135°, in addition to the main fraction at 150–155°, which was practically pure benzyl benzoate; there was also a small amount of a high-boiling product. The origin of dibenzyl ether is discussed below.

It is interesting to note that in several instances mentioned above, nearly half of the total amount of benzoic acid produced could be isolated in the form of the ester. The failure of the reaction to proceed to completion, especially when $10\,N$ alkali was used, is probably entirely a matter of solubility relations, and not of alkali concentration; $106\,\mathrm{g}$. of benzaldehyde was dissolved in $150\,\mathrm{cc}$. of methyl alcohol, and $0.5\,\mathrm{equivalent}$ of sodium hydroxide dissolved in $50\,\mathrm{cc}$. of water was added. The alkali was therefore $2.50\,N$, only $^1/_4$ of the lowest concentration used above. The perfectly homogeneous liquid began to warm up almost immediately; it was placed in cold water, and soon solidified. After $24\,\mathrm{hours}$, $46\,\mathrm{g}$. of benzoic acid and $6\,\mathrm{g}$. of benzyl benzoate were obtained.

Dibenzyl Ether

Dibenzyl ether was first obtained by Cannizzaro, upon heating benzyl alcohol with boric anhydride. Later, Lowe prepared the ether by the action of benzyl chloride on sodium benzoxide. A few years ago, Meisenheimer showed that considerable quantities of dibenzyl ether appear when benzyl alcohol is prepared from benzaldehyde, and he traced its formation to the use of sodium bisulfite to remove unchanged aldehyde. Small amounts of sulfurous acid are retained in the benzyl alcohol, and during its distillation catalytically convert the alcohol into its ether.

During the course of the present work, it has been found that alkalies also convert benzyl alcohol into its ether; $50~\rm g$. of benzyl alcohol, freshly distilled in a vacuum, was warmed on the water-bath for 4 hours with $25~\rm cc.$ of 10~N sodium hydroxide; $0.9~\rm g.$ of dibenzyl ether was obtained. The same quantities, boiled for 2 hours, gave $0.8~\rm g.$

In fact, the dehydration of benzyl alcohol may take place without any catalyst at all, other than the glass vessel in which it is heated; 30 g. of freshly rectified benzyl alcohol was heated in a sealed tube to 210–215° (b. p., 207°) for 5 days. No pressure was observed when the tube was opened. Water had visibly separated; on distilling the mixture, the products obtained were 2.0 g. of water, 6.0 g. of unchanged benzyl alcohol, 3.0 g. of dibenzyl ether, and 17 g. of other substances which came from a decomposition of most of the dibenzyl ether that had formed, namely, 6.9 g. of toluene, 6.1 g. of benzaldehyde, 3.8 g. of high-boiling residue.

The heat decomposition of dibenzyl ether, just referred to, was discovered by Cannizzaro. Lowe repeated the observation; and a brief study was published by Oddo. Lowe gives the decomposition temperature as at or above the boiling point, 295–298°. The reaction occurs, however, at a much lower temperature; 30 g., freshly distilled in a vacuum, was heated for 5 days, in a sealed tube, to 210–215°. No gas was formed; the products were 8.5 g. of toluene, 7.5 g. of benzaldehyde, 8 g. of unchanged ether and 5.5 g. of high-boiling residue. No trace of water was found. The main reaction thus corresponds to the equation

$$C_6H_5-CH_2-O-CH_2C_6H_5 = C_6H_5-CH_3 + C_6H_5CHO$$
 (2)

The bulk of the high-boiling residue is formed from dibenzyl ether and not by condensation of benzaldehyde; the molecular ratio of toluene and of benzaldehyde isolated is 1:0.8. The high-boiling residue is a complex mixture; the chief component is an oil, boiling constant at 217° (5 mm.).

The pyrolytic decomposition of dibenzyl ether is evidently also a matter of intramolecular oxidation and reduction. The reaction sheds light

⁷ Lowe, Ann., 241, 374 (1887).

⁸ Meisenheimer, Ber., 41, 1420 (1908).

⁹ Oddo, Gazz. chim. ital., 31, I, 367 (1901).

on some obscure phenomena. O. and W. F. Kamm¹⁰ have recently discussed the appearance of dibenzyl ether during the preparation of benzyl benzoate. They suggest that the addition product of benzyl benzoate and of sodium benzoxide decomposes as follows,

 $C_6H_5-C(ONa)(OCH_2C_6H_5)_2=C_6H_5-COONa+(C_6H_5-CH_2)_2O$ (3) But benzyl alcohol, when heated with sodium benzoxide, also yields sodium benzoate and dibenzyl ether; 2 g. of sodium was dissolved in 30 cc. of benzyl alcohol, and the mixture heated to 190° for one hour, in a long, open tube. After cooling the reaction mixture and adding water to it, the alkaline liquid gave 1.4 g. of benzoic acid; and the alcohol contained 2.5 g. of dibenzyl ether. As it was possible that benzoic acid owed its production to atmospheric oxygen, the experiment was repeated; the tube was drawn out before the sodium was dissolved, and sealed immediately afterwards. After heating to only 150° for 45 hours, 0.9 g. of benzoic acid, 1.4 g. of dibenzyl ether, and 1.2 cc. of toluene were isolated. No gaseous products were noted.

It is clear that when benzyl alcohol is heated with sodium benzoxide, dibenzyl ether is formed.

 $C_6H_5CH_2OH + C_6H_5CH_2ONa = C_6H_5CH_2-O-CH_2C_6H_6 + NaOH$ (4) The ether undergoes metakliny (oxidation-reduction) as in Equation 2, forming toluene and benzaldehyde; and the latter finally goes over into benzoic acid according to the reaction known by Cannizzaro's name

(Equation 1).11

Perfumers who use benzyl alcohol have trouble in freeing it from dibenzyl ether and above all, from benzaldehyde.¹² The changes described above must go on slowly at ordinary temperatures, and it is more than likely that they are catalyzed by light. Benzyl alcohol distilled at atmospheric pressure will always contain notable traces of both impurities.

The Action of Bromine on Dibenzyl Ether

A measured amount of bromine was slowly dropped into 48 g. of dibenzyl ether. Each addition caused a rapid rise in temperature, and hy-

10 O. and W. F. Kamm, "Organic Synthesis," John Wiley and Son, N. Y., 1922, p. 60.

¹¹ When a mixture of sodium and amyl alcohol is used for reduction, large quantities of valeric acid appear. In order to see whether the mechanism of this reaction is the same as that just described, 1.8 g. of sodium was dissolved in 20 g. of amyl alcohol, and the solution heated in a sealed tube for 24 hours, the temperature gradually rising to 220°. The tube contained hydrogen at very high pressure. After water had been added, the alcohol layer was distilled. The first drop passed over at 92° and all distilled below 135°. Valeraldehyde boils at 93°, amyl ether at 176°. From the first portion of the distillate, phenylhydrazine formed 1.2 g. of hydrazone, equivalent to 0.6 g. of valeraldehyde. The water layer yielded 2.6 g. of valeric acid. Amyl alcohol does not form its ether under the conditions described, but loses hydrogen directly to give the aldehyde: C₄H₂CH₂OH = C₄H₂CHO + H₂.

¹² Compare G. Blanc, C. A., 16, 3308 (1922).

drogen bromide soon passed off. The mixture, which was dark red, was maintained at from 70–100° by its own reaction heat. No bromine fumes were visible above the liquid until 80 g. had been added. The mixture was then slowly distilled; 72 g. passed over below 230°. This colorless liquid, which fumed strongly, was allowed to stand overnight with an excess of sodium carbonate solution; it was then refluxed for 1 hour, cooled, and separated. The oily layer was distilled, passing over completely between 196° and 202°; it was practically pure benzyl bromide, and weighed 32 g. The sodium carbonate solution, when acidified, gave 36 g. of benzoic acid.

The action of bromine on dibenzyl ether is given by the equation

$$C_6H_5CH_2 - O - CH_2C_6H_5 + 2Br_2 = C_6H_5CH_2Br + C_6H_5 - CO - Br + 2HBr \eqno(5)$$

The formation of benzoyl bromide was shown in a separate experiment in which the first distillate was directly treated with alcohol; a large amount of ethyl benzoate was formed, but its separation from benzyl bromide, with nearly the same boiling point, proved difficult. The isolated reaction products, in the experiment detailed above, correspond to a recovery of 80%.

The action of bromine on dibenzyl ether is very similar to that of temperature increase; in both cases metakliny occurs. The yields also correspond closely; making allowance for recovered dibenzyl ether, the amount of toluene found above is 87% of that called for by Equation 2.

The Addition of Benzoyl Bromide to Benzaldehyde

In connection with the present investigation, the substance known as bromobenzyl benzoate was examined. This substance is formed by the addition of benzoyl bromide to benzaldehyde.¹³ Action takes place spontaneously, with development of a little heat; when distilled, the substance passes over at about 200°, with complete dissociation into its components, which reunite slowly on cooling.

The reaction is considered to take place as follows:

$$C_{6}H_{5}-CO-Br + C_{6}H_{5}-CHO = C_{6}H_{5}CO-O-CHBrC_{6}H_{5}$$
 (6)

The present inquiry was directed towards the nature of the linking,—whether the central carbon atoms are tied to oxygen, as shown, or whether perhaps they are directly united. In the latter case, the substance would be related to benzil or benzoin, and most likely have the structure of benzil hydrobromide, $C_6H_5-CO-C(OH)(Br)C_6H_5$.

No such substance could be prepared by melting benzil and passing dry hydrogen bromide over it; no action of any kind took place.

Forty-five g. of crystalline bromobenzyl benzoate was covered with 50 cc. of absolute alcohol, and allowed to stand in a vessel surrounded by cold water until complete solution occurred. Then a slight excess of sodium

¹³ Liebig and Wohler, Ann., 3, 266 (1832). Laurent and Gerhardt, Jahresber., 1850, 489. Schiff, Ann., 154, 347 (1870). Claisen, Ber., 14, 2475 (1881).

carbonate solution was slowly added, and the mixture distilled at low pressure until most of the alcohol passed over. This contained a small amount of ethyl bromide which was not estimated. After extraction with ether and evaporation of the solvent, an oil was obtained which upon distillation gave 15.9 g. of benzaldehyde, and 8.8 g. of ethyl benzoate; no benzil, benzoin, or other high-boiling residue could be noted. From the sodium carbonate solution 11.8 g. of benzoic acid was recovered.

From these results, bromobenzyl benzoate must be regarded as a compound with oxygen linking, as indicated by its name.

The Mechanism of Cannizzaro's Reaction

The data in the present paper afford definite proof that benzyl benzoate is an intermediate in Cannizzaro's reaction. We can hardly assume that this ester is formed from benzyl alcohol and sodium benzoate in the presence of hydroxyl ion. With reference, however, to the two molecules of benzaldehyde from which it is produced

$$C_6H_5CHO + C_6H_5CHO = C_6H_6CO-O-CH_2C_6H_5$$
 (7)

benzyl benzoate represents the *completion* of an oxidation-reduction process. There must be antecedent steps.

It is well known that compounds containing the carbonyl group readily add sodium alkoxide.¹⁴ These addition products are known to show strongly additive properties towards other carbonyl compounds.¹⁵ We may write the following equation, using (OR) as equivalent to OH or to any alkoxide ion:

 $C_6H_5CH(OR)ONa + C_6H_5CHO = C_6H_5CH(OR)-O-CH(ONa)C_6H_5$ (8) This is entirely analogous to the formation of bromobenzyl benzoate, Equation 6.

The addition product assumed in Equation 8 is closely related to dibenzyl ether; it is a derivative of dihydroxy-dibenzyl ether.

$$C_6H_5CH(OH) - O - CH(OH)C_6H_5$$
 (9)

Dihydroxy-dibenzyl ether is a sort of glycol, and must be expected to undergo readily the typical hydroxyl shift. ¹⁶ Applying this metaklinic mechanism to the compound assumed in Equation 8, we have

This mechanism, while largely hypothetical and based on reasoning by analogy, seems to be the best available picture of Cannizzaro's reaction, at the present time. It accounts for the formation of mixed esters, as

¹⁴ The reaction is probably ionic, addition of OH⁻ or OR⁻. The hydroxide addition products are usually too soluble or too reactive to be isolated, but the work of Kohn and Tranton (Ref. 4) shows their existence in the present instance.

¹⁵ Compare Scheibler and Ziegner [Ber., 55B, 789 (1922)] for a recent and somewhat striking example of this type of reaction.

Lachman, This Journal, 44, 336 (1922).

observed by Claisen and by Tischtschenko. It also shows how a small amount of NaOR can act catalytically, as it does in the Claisen method of preparing benzyl benzoate. While the glycol shift, in general, is catalyzed by acids, aromatic glycols, such as benzopinacol, are also acted upon by alkalies. The separation of the hydroxyl groups is no barrier to the shifting process, for β -glycols, containing the group, -C(OH)-CH-C(OH-, also rearrange in typical fashion.

A similar mechanism will account for the behavior of dibenzyl and dibromobenzyl ether (Equations 2 and 5). As no hydroxyl groups are present, rearrangement is brought about by a shift of hydrogen, and a readjustment of electrons.

Conclusion

While it is advisable to postpone a discussion of the details of electron readjustment until further data have been collected, a few general rules may be stated, which seem to apply to the field covered in the present series of papers.

- 1. Hydroxyl groups attached to two neighboring carbon atoms (α or β -position) rearrange to give a carbonyl group, with loss of water.
- 2. A single hydroxyl group, at least in primary alcohols, tends to form a carbonyl group (aldehyde). The behavior of benzyl and of amyl alcohol illustrates two widely different modes of reaching the same end-point.
- 3. The carbonyl group tends to add hydroxyl or alkoxyl ion, and go over into carboxyl ion.
- 4. The readjustment of carbonyl to carboxyl necessarily involves the severance of a carbon-carbon bond; this may occur by *rupture*, producing two smaller molecules, or by rearrangement of the carbon chain. Other things being equal, the latter mode seems to be preferred.¹⁷
- 5. The preference for rearrangement over rupture applies also to reactions under Rule 1.

The phenomena of condensation, as in the case of the formation of aceto-acetic ester, seem to contradict Rule 3, but the contradiction is more apparent than real. Condensation is an intermediate step; and a continuation of the process, by the same reagents, leads to carboxyl formation.

One cannot but be struck by the almost purposeful behavior of some chemical substances. Who could have predicted the sequence shown in the conversion of benzyl alcohol into benzoic acid: benzyl alcohol, dibenzyl ether, benzaldehyde, Cannizzaro mechanism, benzyl benzoate, benzoic acid? Is there much difference between such a series of events, and what we call "instinct?"

¹⁷ Compare the behavior of dihydroxytartaric acid; This Journal, **43**, 2091 (1921). This conversion of carbonyl to carboxyl is also discussed, *ibid.*, **45**, 1533 (1923).

Summary

- 1. When aqueous alkalies act upon benzaldehyde, benzyl benzoate is a primary product.
- 2. Dihydroxy-dibenzyl ether is indicated as a prior intermediate, and a mechanism for its formation and its conversion into benzyl benzoate by a glycol-like rearrangement is given.
- 3. In the development of this problem, some properties of benzyl alcohol and of dibenzyl ether are studied.

THE ACTION OF CHLORAL ON CELLULOSE

By J. H. Ross and J. M. Payne Received May 7, 1923

Hefter¹ by heating a mixture of glucose and anhydrous chloral at 100° obtained two condensation products of chloral with glucose, namely chloralose (m. p., 187°) and parachloralose (m. p., 227°). Petit and Polonowski² and Hanriot and Richtet³ catalyzed the reaction by the addition of a small quantity of hydrochloric acid and obtained the same condensation products. Meunier,⁴ using a large quantity of concd. sulfuric acid, carried out the same condensation with chloral hydrate. In addition to the two chloraloses he isolated a dichloralglucose (m. p., 225°) and a chloralglucosan (m. p., 225°). F. H. Reichel⁵ treated glucosan and levoglucosan with chloral hydrate and sulfuric acid and obtained two additional dichloralglucoses (m. p., 268°, 85°). From glucosan he obtained parachloralose but no chloralose, whereas from levoglucosan he obtained chloralose but no parachloralose.

The object of the present investigation was to obtain chloral derivatives of cellulose which might be degraded to chloral-substituted glucoses and to compare them with similar derivatives from starch.

No definite products were obtained by the action of chloral or its hydrate on cellulose even in the presence of catalysts such as hydrochloric acid or zinc chloride. By the use of concd. sulfuric acid and chloral hydrate, as described by Meunier, cellulose yielded considerable quantities of chloral-glucoses but no chloral-substituted celluloses or cellulose dextrins.

Experimental Part

Fifty g. of surgical cotton was gradually stirred into a mixture of 100 g. of chloral hydrate and 100 cc. of concd. sulfuric acid contained in a beaker cooled in snow. The

 - ² Petit and Polonowski, Bull. soc. chim., [3] 11, 125 (1894).
 - ³ Hanriot and Richtet, ibid., [3] 9, 947 (1893); [3] 11, 37, 303 (1894).
 - ⁴ Meunier, Compt. rend., 122, 142 (1896); Ber., (Ref.) 29, 177 (1896).
- ⁸ Reichel, Thesis, University of Geneva, 1921. Pictet and Reichel, Helvetica Chim. Acta, 6, 621 (1923).

dissolution of the cotton was rapid with little discoloration and small evolution of heat. The reaction was then allowed to proceed at room temperature and occasionally stirred.

At the end of 2 hours a skin had formed at the surface of the liquid and on 12 hours' standing a thick, solid layer had formed there. This was removed and ground underwater in a mortar, giving a light gray flocculent, or at times granular, precipitate. The remaining liquid was poured into a large volume of cold water whereupon it gave a further quantity of the gray precipitate.

The precipitate was boiled in 600 cc. of water until it formed a soft gum, and only traces of chloral came off in the vapors. The water was decanted and a further 600 cc. containing from 5 to 10 cc. of coned. nitric acid was added and the mixture boiled for about 10 minutes, whereupon the water was decanted. The gum hardened as it cooled and was easily broken up under water in a mortar. Filtered and dried, it weighed about 69 g. When extracted with about 200 cc. of alcohol and filtered hot it left a residue which was further purified by solution in hot acetone from which it precipitated on cooling. This is named Fraction I.

From the alcohol as it cooled there precipitated a crystalline compound named Fraction II; when this is removed by filtration and the filtrate is concentrated to about $\frac{1}{3}$ of its original volume a further quantity of Fraction II is obtained.

The mother liquors were concentrated on a bath until two layers were formed. The upper layer was quite clear, the lower layer was dark brown. This latter solidified as it cooled. The upper layer was decanted and the solid dissolved in carbon tetrachloride from which a crystalline compound separated on cooling, named Fraction III. The carbon tetrachloride solution was evaporated to a thick sirup which hardened as it cooled and was named Fraction IV.

Fraction I.—This was obtained as triangular or 6-sided plates from hot acetone or alcohol; m. p., 268°. It is slightly soluble in hot acetone, pyridine, acetic acid, alcohol, or concd. nitric acid, and is insoluble in ether, chloroform, carbon tetrachloride, petroleum ether, water, or hot or cold alkalies. Its solution in pyridine is levorotatory. It does not reduce Fehling solution.

Analyses. Subs., 0.1465: AgCl, 0.2833. Subs., 0.1627: CO₂, 0.1621; H₂O, 0.0334. Calc. for $C_{10}H_{10}O_6Cl_6$ (Reichel's dichloral glucose): C, 27.40; H, 2.30; Cl, 48.59. Found: C, 27.17; H, 2.30; Cl, 47.84.

The mono-acetate was prepared from acetic anhydride and sulfuric acid. It crystallizes from ether in needles; m. p., 198° ; $[\alpha]_p - 12^{\circ}$ (c. $5.0)^6$ in CHCl₃.

Analysis. Subs., 0.1518: AgCl, 0.2178. Calc., mono-acetate: Cl, 44.25. Found: 44.30.

Upon methylation with dimethyl sulfate and sodium hydroxide, hairy needles were obtained from alcohol; m. p., about 200°; $[\alpha]_p - 17$ (c. 5.0) in 1:1 acetone-pyridine.

Analysis. Subs., 0.1612: AgCl, 0.3055. Calc. for $C_{11}H_{12}O_5Cl_6$: Cl, 46.98. Found: 46.89.

Fraction II.—Recrystallized from alcohol, this was obtained as needles; m. p., 225; $[\alpha]_b - 15$ (c. 1.2) in chloroform. It is not very soluble in carbon tetrachloride, and is insoluble in cold petroleum ether, water or alkalies. It does not reduce Fehling solution.

Analyses. Subs., 0.1377: AgCl, 0.2728. Subs., 0.1840: CO₂, 0.1830; H₂O, 0.0379. Found: C, 27.12; H, 2.30; Cl, 49.01.

Acetylation gives a product that forms thick, rectangular crystals from alcohol or ether; m. p., 126° ; [α]_D -21.4 (c. 4.67) in chloroform.

Analysis. Subs., 0.1567: AgCl, 0.2799. Calc. for C₁₂H₁₂O₇Cl₆: Cl, 44.25. Found: 44.19.

A concentration of 5 g. in 100 cc. of solution.

After methylation the substance became too soluble in organic solvents to purify by crystallization; m. p., about 110° ; $[\alpha]_{\rm p} - 23$ (c. 5) in chloroform.

Analysis. Subs., 0.1540: AgCl, 0.2820. Found: Cl, 45.46.

Fraction III.—This crystallizes from hot water in long needles that are soluble in most organic solvents; m. p., $135-136^{\circ}$; $[\alpha]_{\rm D}+32$ (c. 7.754) in benzene; $[\alpha]_{\rm D}+10.5$ (c. 7.617) in chloroform. The substance is soluble in cold, concd. nitric acid, but insoluble in alkalies.

It does not reduce Fehling solution even after it has been boiled with acids.

Analyses. Subs., 0.1433: AgCl, 0.2745. Subs., 0.1616: CO₂, 0.1471. H₂O, 0.0331. Found: C, 24.82; H, 2.29; Cl, 47.39.

Fraction IV.—This was a very impure fraction. The chief impurity seems to be Fraction II which may be precipitated from solution in alcohol by cautiously adding petroleum ether; m. p., about $74-75^{\circ}$; [α]_D +14 (c. 8.12) in chloroform. It is insoluble in water and alkalies.

Although the original substance does not reduce Fehling solution, reduction of this reagent takes place after the substance has been boiled with dil. acids. Nitric acid produces a compound that is precipitated by sodium hydroxide. Heated in a vacuum it loses 2.8% of its weight and then reduces Fehling solution. Its chlorine content is within 1% of that of a dichloralglucose.

Hydrocellulose, starch and glucose treated with sulfuric acid and chloral hydrate yield four fractions similar to those mentioned above. Glucose gives a lower yield of Fraction IV than do the other carbohydrates by this reaction. The liquors remaining from the precipitation of the dichloral sugars in water, when heated on the water-bath, precipitate a quantity of parachloralose. A large quantity of parachloralose is deposited from the water and dil. nitric acid after the precipitate obtained from starch and glucose has been boiled; this does not happen in the case of cellulose and hydrocellulose.

Conclusions

The action of chloral hydrate on starch and cellulose gives rise to identical dichloralglucoses.

Monochloralglucoses could not give rise to dichloralglucoses by condensation with a second molecule of chloral. The former have four free hydroxyls, which points to aldol condensation; while the latter possess but one free hydroxyl, which indicates acetal condensation throughout.

Since it has been claimed by previous workers in this field that parachloralose is produced by the α -anhydro-glucosidic linkage of d-glucosan and never by the β -anhydro-glucosidic linkage of l-glucosan, the formation of parachloralose from cellulose might indicate the pre-existence of one or more α linkages in the cellulose molecule.

Summary

1. Cotton cellulose was acted on by chloral hydrate using a large excess of sulfuric acid as a condensing agent. No chloral-substituted cellulose or cellulose dextrines were isolated, but from the reaction mixture four compounds were obtained, two of which corresponded in every way to two known dichloral glucoses (both levorotatory), m. p. 268° and 225°, respectively. The other two compounds gave analyses approximately

that of dichloral glucose (both dextrorotatory), m. p., 135° and 74°, respectively.

The same four compounds were formed in a similar manner from starch and glucose.

- 2. Acetylation and methylation of the two levorotatory compounds showed the presence of only one free hydroxyl group. No crystalline compounds were obtained by these reactions on the dextrorotatory compounds.
- 3. Parachloralose was formed when the crude water-insoluble products of starch and glucose, but not those of cellulose, were boiled. The soluble reaction products from all three, however, produced parachloralose when heated, after dilution, on the water-bath.

MOLECULAR REARRANGEMENTS OF THE CAMPHOR SERIES. XIV. STRUCTURE OF ISOCAMPHOLACTONE¹

By Philip Kelsey Porter with William A. Noves

RECEIVED MAY 14, 1923

Isocampholactone was first prepared by Noyes^{2a} by the action of nitrous acid on aminolauronic acid. It was later prepared by $\operatorname{Bredt}^{2b}$ in a pure condition by decomposing the nitroso derivative of the anhydride of aminolauronic acid with sodium hydroxide. Noyes and Homberger³ oxidized isocampholactone with nitric acid and isolated two products, one the nitro-isocampholactone and the other a lactone acid which was the lactone of an hydroxy dicarboxylic acid and has the formula, $O = C - O - C_7 H_{11} COOH$. The amide of this lactone acid was prepared.

Nitro-isocampholactone was decomposed by dil. alkaline reagents forming an acid which has the formula $C_5H_8NO_2COOH$. Three carbon atoms and four hydrogen atoms were lost by the reaction but the other product of the reaction was not isolated. The amide of this acid was also prepared.

The structure of isocampholactone had not been determined when the investigation here described was begun. We have shown that it has Formula I.

¹ An abstract of a thesis presented by Philip K. Porter in partial fulfilment of the requirements for the degree of Doctor of Philosophy at the University of Illinois, June, 1923.

^{2b} Bredt., Ber., 35, 1291 (1902).

³ Noyes and Homberger, This Journal, 32, 1665 (1910).

The lactone acid which was obtained by Noyes and Homberger³ was converted to the disilver salt from which the dimethyl ester was prepared. On treatment of the hydroxy ester with Beckmann's⁴ chromic acid mixture, which oxidizes primary and secondary hydroxy groups but not tertiary, the hydroxy group was shown to be tertiary and not secondary as it would be if no rearrangement had occurred. The lactone acid gives an amide which on treatment with sodium hypobromite is converted to a keto acid. The amide group and the hydroxy group are, therefore, on the same carbon atom. On treatment with sodium hypobromite, if the amino and hydroxy groups are on the same carbon atom, these split off ammonia, forming the keto group similar to the preparation of camphononic acid from camphanamide.⁵

This keto acid on treatment with methylmagnesium iodide regenerates isocampholactone and also forms another acid, which is probably the *trans*-hydroxy acid, as might be expected from the reaction. This compound was not fully identified however.

This series of reactions demonstrates that isocampholactone contains methyl groups in the 1,2,3 positions instead of the 1,2,2 positions of camphoric acid and should be called the lactone of 3-hydroxy-1,2,3-trimethyl cyclopentane-carboxylic acid.

The isomerism of campholactone and isocampholactone may be explained when we consider the second asymmetric carbon atom. Lauronolic acid, from which campholactone is formed, has a double bond which would cause the two methyl groups to be in the same plane, as shown in Formula II. On breaking the double bond to form the hydroxy acid, campholactone is formed and would have Structure III. Isocampholactone then would have the second methyl group in the *trans* position with reference to the other two methyl groups. We consider this explanation as very probable but not as definitely proved. The work here described proved the structure of isocampholactone conclusively but can not be considered conclusive concerning its stereometric configuration.

Nitro-isocampholactone, which evidently has the nitro group in the 2 position, was decomposed by sodium hydroxide in such a manner as to isolate the volatile reaction products; 60% of the calculated amount

⁴ Beckmann, Ann., 250, 325 (1889).

⁵ Lapworth and Lenton, J. Chem. Soc., 79, 1293 (1901).

of acetone was obtained. The only possible explanation of this reaction is shown in the following formulas:

The acid is either a cyclobutane derivative with a secondary nitro group or a cyclopropane derivative with a tertiary nitro group. The nitrous acid test⁶ applied to the amide, the acid or its ester gives a blue solution which is the test for a secondary nitro group. Secondary nitro groups would enolize and form a sodium salt when treated with sodium alcoholate. The amide and the methyl ester of the acid formed sodium salts quite easily in quantitative yields. Hydrolysis of the sodium salt of an enolic nitro group with dil. sulfuric acid would form a ketone if the nitro group is secondary, and a blue solution would be formed, while nitrous oxide would be given off. Hydrolysis of the sodium salt of the amide showed that no gas and no color was given to the solution. The original nitro acid was isolated from the reaction mixture.

Hydrolysis of the sodium salt of the methyl ester gave a deep blue solution and about $^{1}/_{3}$ of the calculated amount of nitrous oxide was obtained along with about the same amount of carbon dioxide. However, the original nitro acid was the only product isolated from the reaction. The keto acid which would form α -methyl-glutaric acid was not isolated, although the reaction seemed to have partially taken place. The nitrous acid test and the formation of the sodium salt of an enolic nitro group proves that this acid is a cyclobutane derivative and should be called 2-nitro-1-methyl-cyclobutane-carboxylic acid.

Experimental Part

Oxidation of Isocampholactone.—The isocampholactone required for these experiments was prepared by decomposing the nitroso derivative of the anhydride of aminolauronic acid with sodium hydroxide; 65 g. of isocampholactone was heated for 72 hours

⁶ V. Meyer, Ann., 175, 93, 120 (1875).

⁷ V. Meyer, Ann., 256, 28 (1889).

⁸ Nef, Ann., 280, 273, 267 (1894).

⁹ Noyes and Taveau, Am. Chem. J., 32, 288 (1904).

with nitric acid, d. 1.27, 10 and 40 g. of nitro-isocampholactone was obtained; m. p., 121–122°; yield, 47.6%.

The mother liquors from the oxidation were evaporated to dryness. The viscous residue was dissolved in benzene upon evaporation of which crystals appeared; 11.7 g. of the lactone acid or the lactone of 3-hydroxy-1,2-dimethyl-cyclopentane-dicarboxylic acid was obtained; m. p., 136-138°.

Analyses. Subs., 0.1621: CO_2 , 0.3493; H_2O , 0.1010. Calc. for $C_9H_{12}O_4$: C, 58.67; H, 6.57. Found: C, 58.77; H, 6.98.

The Dimethyl Ester of 3-Hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic Acid.—0.9666 g. of the lactone of 3-hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic acid was dissolved in the calculated amount of sodium hydroxide by heating them together on the water-bath for 24 hours. The silver salt was obtained by adding an excess of silver nitrate; 1.9788 g. of salt was obtained or 90.5%.

Analysis. Subs., 0.2437: AgCl, 0.1683. Calc. for $C_9H_{12}O_5Ag_2$: Ag, 51.88. Found: 51.97.

The methyl ester was obtained by treating an ether solution of 1.1093 g. of silver salt with methyl iodide; 0.5343 g. of the ester was obtained; yield, 87.8%; b. p., 156–160° (25 mm.).

Analyses. Subs., 0.2053: CO₂, 0.4341; H₂O, 0.1439. Calc. for C₁₁H₁₈O₅: C, 57.39; H, 7.83. Found: C, 57.66; H, 7.86.

Beckmann's chromic acid mixture⁴ oxidizes primary and secondary hydroxyl groups but not tertiary hydroxy groups. On treating the ester with Beckmann's reagent, only a slight darkening in color (a test for a tertiary hydroxy group) was produced even after the mixture had stood for 12 hours.

The 3-Amide of the Lactone of 3-Hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic Acid.—1.1559 g. of the lactone of 3-hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic acid was heated for 5 minutes in a 50cc. flask with 1.3 g. of phosphorus pentachloride. The phosphorus oxychloride was distilled under diminished pressure and 5 cc. of dry ether was then added to dissolve the acid chloride. Cold concd. ammonium hydroxide (d., 0.9) was slowly added until the solution was strongly ammoniacal, after which the excess was evaporated under diminished pressure. The dry residue was dissolved in hot benzene, from which the amide crystallized. It was recrystallized from benzene; yield, 0.8638 g. or 75%; m. p., 162–163°.

3-Keto-1,2-dimethyl-cyclopentane-carboxylic Acid.—2.02 g. of the 3-amide of the lactone of 3-hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic acid was dissolved in 14.3 cc. of a 10% solution of sodium hydroxide. After cooling the solution, the calculated amount of a cold sodium hypobromite solution was added. The reaction mixture was allowed to remain at room temperature for 12 hours and then heated on the waterbath for one hour. The cold solution was acidified with dil. sulfuric acid. Sodium sulfite was added to remove free bromine. The 3-keto-1,2-dimethyl-cyclopentane-carboxylic acid was extracted with ether and the extract dried over sodium sulfate. After distilling the ether, the acid was obtained as an oily residue from which 1.85 g. of the barium salt was obtained. The phenylhydrazone and the p-bromophenylhydrazone of the keto acid were prepared, both being oily materials. A crystalline hydrazone was not isolated.

Action of Grignard's Reagent on 3-Keto-1,2-dimethyl-cyclopentane-carboxylic Acid. Preparation of Isocampholactone.-Methylmagnesium iodide was slowly added to an ether solution of 3-keto-1,2-dimethyl-cyclopentane-carboxylic acid in the proportion of two moles of the former to one mole of the latter; 3.4 g. of methyl iodide was dissolved in 4 cc. of dry ether and the solution was added to 0.5837 g. of magnesium ribbon covered with ether. The methylmagnesium iodide thus formed was slowly added to an ether solution of 1.8665 g. of the keto acid. A complex was formed immediately. The reaction mixture was slowly refluxed for 20 minutes, after which it was cooled and the complex was decomposed by the addition of 2.5 cc. of 1:1 sulfuric acid. The ether extract was washed with a solution of sodium acid sulfite to remove the free iodine and then washed with a 10% solution of sodium carbonate to remove the unchanged keto acid and the trans-hydroxy acid which would be formed by the reaction, after which it was dried over sodium sulfate. On evaporation of the ether, a viscous residue was obtained which was further purified by steam distillation. The distillate was again extracted with ether and a solid was obtained which melted at 31-32°. A mixed melting point with pure isocampholactone was $31-32^{\circ}$; $[\alpha]_{D}^{26}-60.1^{\circ}$ (0.1406 g. in 5 cc. of absolute alcohol). Noves and Homberger¹² gave $[\alpha] - 63.1^{\circ}$.

To prove further its identity with isocampholactone, nitro-isocampholactone was prepared from this material by treatment with nitric acid, and was found to melt at 120–121°. A mixed melting point with pure nitro-isocampholactone was 120–121°; $[\alpha]_D^{26} - 88.6$ ° (0.0326 g. in 5 cc. of absolute alcohol). Noyes and Homberger¹² gave $[\alpha] - 85.4$. This reaction definitely proves the structure of isocampholactone; it should be called the lactone of 3-hydroxy-1,2,3-trimethyl-cyclopentane-carboxylic acid.

The sodium carbonate solution of the *trans*-hydroxy acid and unchanged keto acid was acidified and extracted with ether. An oily material was obtained. It was found that the calcium or barium salt of the hydroxy acid was difficultly soluble. This enabled a rough separation of the two acids to be made. A white solid was obtained which was acidic and melted at $96-97^{\circ}$; $[\alpha]_{10}^{28}$ — 37.5° (0.1681 g. in 5 cc. of absolute alcohol).

Treatment of this hydroxy acid with fuming hydrobromic acid failed to give the corresponding bromo acid. The presence of the hydroxy group was not positively shown, yet from its method of formation it seems quite probable that the material melting at 96–97° was a *trans*-hydroxy acid.

The Amide of 2-Nitro-1-methyl-cyclobutane-carboxylic Acid.—0.3257 g. of nitro-isocampholactone was slowly decomposed by 5 cc. of coned. ammonium hydroxide, 12 the excess being evaporated under diminished pressure. The dry residue was dissolved in hot benzene from which the amide crystallized; yield, 0.215 g., or 83%; m. p., 94-95°.

Analyses. Subs., 0.1686: CO₂, 0.2806; H₂O, 0.1013. Calc. for C₅H₈NO₂CONH₂: C, 45.5; H, 6.3. Found: C, 45.4; H, 6.73.

Subs., 0.0987; 15.8 cc. of N₂ (25°, 744.5 mm.). Calc. for $C_5H_8NO_2CONH_2$: N, 17.72. Found: 17.41.

2-Nitro-1-methyl-cyclobutane-carboxylic Acid.—Nitro-isocampholactone was decomposed by warming it with about 2N sodium hydroxide solution. When all of the nitro-isocampholactone had dissolved, the solution was acidified and the 2-nitro-1-methyl-cyclobutane-carboxylic acid was extracted with ether. It was converted to the barium salt and crystallized from water in long needles. The yields varied from 80 to 100%.

¹² Ref. 3, p. 1668.

In the first attempts to determine the other reaction product, the reaction was carried on in a flask sealed to a drying tube which was in turn connected to a combustion tube, and the volatile reaction product burned and analyzed. About 1/2 of the calculated amount of carbon and hydrogen which was lost by the reaction was accounted for by this arrangement.

Finally, 4.6931 g. of nitro-isocampholactone was decomposed by sodium hydroxide in a 100cc. flask which was connected to a 50cc. flask (cooled with ice and salt) by a tube that extended to the bottom of the flask. This flask was in turn connected to a 5cc. flask by a tube which extended to the bottom of the flask and was cooled by carbon dioxide snow and ether. The reaction mixture was slowly warmed on a water-bath until all of the nitro-isocampholactone had dissolved. Then it was slowly boiled until about 15 cc. of liquid had collected in the 50cc. flask. This material was boiled until about 3 cc. had collected in the 5cc. flask. The liquid material, which was acetone, was distilled; b. p., $56-58^{\circ}$; yield, 60%. It was identified as being acetone by the iodoform test and by the preparation of dibenzylidene acetone which melted at $111-112^{\circ}$.

The free acid was obtained from the barium salt by acidifying the solution of salt and extracting the acid with ether; m. p., $70-72^{\circ}$. The specific rotation was taken with a mercury-vapor lamp as the source of light at three different wave lengths, corresponding to the yellow line or $546.1\mu\mu$, the green line or $578\mu\mu$, and the blue line or $435\mu\mu$, and also with a sodium vapor light; $[\alpha]_{578}^{25}$, —101.51°; $[\alpha]_{435}^{25}$, —246.81°; $[\alpha]_{546.1}^{25}$, —119.3°; $[\alpha]_{546.1}^{25}$, —87.31°.

Subs., 0.1835: H_2O , 0.0178 (at 80° for 2 hours). Calc. for $(C_5H_9NO_2COO)_2Ba.-2^1/_2H_2O$: H_2O , 9.04. Found: 9.70.

Nitrous Acid Test for the Secondary Nitro Group.—According to V. Meyer, introus acid reacts with primary nitro groups to form a red solution of a nitrolic acid and with secondary nitro groups to form a blue solution of a pseudonitrole, while it does not react with tertiary nitro groups. The 2-nitro-1-methyl-cyclobutane-carboxylic acid and its corresponding amide and methyl ester were treated with nitrous acid and the blue color obtained in each case. The results of this test support the cyclobutane formula.

Silver Salt of 2-Nitro-1-methyl-cyclobutane-carboxylic Acid.—5.261 g. of the barium salt was dissolved in a small amount of water and an excess of silver nitrate was added; 4.122 g. of the silver salt was obtained; yield, 73.2%. The salt is slightly soluble in water and darkens on exposure to the light.

Analyses. Subs., 0.1104, 0.1281: AgCl, 0.0596, 0.0692. Calc. for C₆H₈NO₂-COOAg: Ag, 40.56. Found: 40.62, 40.65.

Methyl Ester of 2-Nitro-1-methyl-cyclobutane-carboxylic Acid.—4.122 g. of the silver salt was suspended in ether and a solution of 10 cc. of methyl iodide dissolved in 10 cc. of ether was added. The mixture was refluxed on a water-bath for 6 hours. The silver iodide was filtered off and the ether evaporated in a vacuum; 2.4335 g. of the ester was obtained; yield 90.7%. The ester boiled at $120-125^{\circ}$ at 5 mm. pressure with some decomposition. The specific rotation was taken with a mercury vapor lamp as a source of light at two different wave lengths, that corresponding to the yellow line or $578.1\mu\mu$ and that corresponding to the green line or $546.1\mu\mu$; $[\alpha]_{578.1}^{25}$, -90.2° ; $[\alpha]_{546.1}^{25}$, -93.2° ; $[\alpha]_{1.16907}^{25}$; n, 1.4416.

Treatment of the Amide of 2-Nitro-1-methyl-cyclobutane-carboxylic Acid with Sodium Alcoholate and the Hydrolysis of the Sodium Salt.—1.27 g. of the amide was dissolved in absolute alcohol and the calculated amount of sodium alcoholate was added. After this had stood at room temperature for two hours, two volumes of dry ether was added and the sodium salt was precipitated and filtered off. It was dried in a vacuum desiccator. The yield was quantitative.

Analyses. Subs., 0.1762, 0.1046, 0.1247, 0.1538: Na₂SO₄, 0.0630, 0.0393, 0.0446, 0.0564. Calc. for C₆H₉N₂O₃Na: Na, 12.77. Found: 11.58, 12.17, 11.66, 11.87.

Subs., 0.1071, 0.0897: NaCl, 0.0335, 0.0282. Calc. for $C_6H_9N_2O_3Na$: Na, 12.77. Found: 12.31, 12.35.

On hydrolysis of the sodium salt with dil. sulfuric acid, no gas was given off and the solution was only a faint blue. The solution was extracted with ether and a solid was obtained melting at $70-72^{\circ}$. A mixed melting point with pure 2-nitro-1-methyl-cyclobutane-carboxylic acid was $68-70^{\circ}$.

Treatment of the Amide with Two Molecular Equivalents of Sodium Hydroxide.—One g. of the amide was warmed with 5 cc. of a 10% solution of sodium hydroxide until the ammonia had ceased to come off. The residue was attached to a gas buret and acidified. A blue color was obtained which disappeared on warming. A gas was given off which caused a glowing splinter to burn, which is a qualitative test for nitrous oxide. About 1/3 of the theoretical amount of gas was given off. The reaction mixture was extracted with ether and an oily acidic material obtained. The silver salt was prepared.

Analysis. Subs., 0.0723: AgCl, 0.0386. Calc. for $C_6H_8NO_4Ag$: Ag, 40.56. Found: 40.18.

Recovery of the acid from the analysis gave a product melting at 71–72°. A mixed melting point with pure 2-nitro-1-methyl-cyclobutane-carboxylic acid was 69–70°.

Treatment of the Methyl Ester of 2-Nitro-1-methyl-cyclobutane-carboxylic Acid with Sodium Alcoholate and the Hydrolysis of the Sodium Salt.—2.27 g. of the ester was dissolved in absolute alcohol and the calculated amount of sodium alcoholate was added. After this had stood for a few hours, two volumes of dry ether was added, which precipitated the sodium salt. This was filtered off and dried in a vacuum desiccator. It is very unstable and decomposes easily. The yield, however, was almost quantitative. The analysis was made on very impure material because of decomposition.

Analyses. Subs., 0.1143, 0.0853, 0.1072: Na_2SO_4 , 0.0660, 0.0513, 0.0683. Calc. for $C_7H_{10}NO_4Na$: Na, 12.57. Found: 18.70, 19.48, 20.64.

Hydrolysis of the sodium salt with dil. sulfuric acid gave a blue solution, and about $^{1}/_{3}$ of the calculated amount of nitrous oxide was obtained that was identified by the test with a glowing splinter. About the same amount of carbon dioxide was also obtained. The reaction mixture was extracted with ether and the oily residue which was obtained was treated with barium carbonate, which separated the unchanged ester from the acids; these may be a mixture of the original nitro acid and the keto acid, which would break down into α -methyl-glutaric acid. The barium salts were fractionally crystallized. Since the barium salt of the nitro acid is difficultly soluble, the most soluble portion was converted into the silver salt.

Analysis. Subs., 0.1300: AgCl, 0.0921. Calc. for $C_6H_8O_4NAg$: Ag, 40.56; calc. for $C_6H_7O_3Ag$: 45.92; calc. for $C_6H_8O_4Ag_2$: 59.96. Found: 53.318.

The mixed acids obtained from a second experiment were warmed with acetyl chloride to form the anhydride of the α -methyl-glutaric acid and distilled. The low-boiling fraction, boiling at 130–140° (5 mm.), was taken. It was then boiled with water to regenerate the acid, and the silver salt was prepared.

Analysis. Subs., 0.0614: AgCl, 0.0428. Found: Ag, 52.46.

The analyses and the behavior of the reaction indicates that α -methyl-glutaric acid might have been formed, but in quantities too small to be isolated.

Summary

- 1. When isocampholactone is heated with nitric acid, the two main products formed are nitro-isocampholactone and a lactone acid. This lactone acid gives an amide which on treatment with sodium hypobromite is converted to a keto acid. This, on treatment with methylmagnesium iodide, regenerates isocampholactone and also probably forms a *trans*-hydroxy acid. This series of reactions demonstrates that isocampholactone contains methyl groups in the 1,2,3 positions and should be called the lactone of 3-hydroxy-1,2,3-trimethyl-cyclopentane-carboxylic acid.
- 2. A possible explanation of the isomerism of campholactone and iso-campholactone is given.
- 3. Nitro-isocampholactone on treatment with alkali gives almost quantitatively acetone and a nitro acid of 6 carbon atoms. The nitro group in this acid is secondary, as proved by the nitrous acid test and by the formation of a sodium salt of the enolic form of the nitro group in both the acid and its ester. This test proves that it is a cyclobutane derivative and should be called 2-nitro-1-methyl-cyclobutane-carboxylic acid.

SIMPLIFICATION OF THE GATTERMANN SYNTHESIS OF HYDROXY ALDEHYDES

By Roger Adams and I. Levine¹ Received May 21, 1923

The Gattermann synthesis of hydroxy aldehydes² which consists in saturating an anhydrous ether solution of certain phenols and anhydrous hydrogen cyanide with dry hydrogen chloride, sometimes with the addition of anhydrous zinc chloride, gives excellent yields of products which are readily purified. The method has proved to be invaluable for the preparation of certain intermediates in the synthesis of many natural compounds, and is still the only available process for preparing many representative hydroxy aldehydes. In spite of the ease with which the reaction generally takes place, its use in the laboratory is not as frequent as might be expected. This is due to the necessity of using anhydrous hydrogen cyanide, a product the preparation and handling of which in-

¹ This communication is an abstract of a thesis submitted by I. Levine in partial fulfilment of the requirements for the degree of Master of Science in Chemistry at the University of Illinois.

volve many disagreeable features. More recently,³ this method of preparation of the hydroxy aldehydes has been simplified somewhat by the generation of the hydrogen cyanide and its direct addition to the reaction mixture. Even this procedure does not make the preparation safe for any but the more experienced investigator. Such reactions as the Gattermann synthesis, involving anhydrous hydrogen cyanide, are consequently limited in their use.

Recently Karrer⁴ has shown that bromocyanogen may be substituted for hydrogen cyanide in the preparation of certain hydroxy aldehydes. The yields, however, do not appear to be as satisfactory as when hydrogen cyanide is used. Bromocyanogen is more conveniently made in the laboratory and more easily handled than anhydrous hydrogen cyanide, but even this product is extremely poisonous and much care must be used. Moreover, only a freshly prepared sample of bromocyanogen gives satisfactory results.

This research had as its object the modification of the Gattermann synthesis in such a way as to avoid using anhydrous hydrogen cyanide. Experiments in which hydrogen cyanide was replaced by certain of its salts have been carried out. Of these various salts, zinc cyanide would seem the most promising choice, since it would be changed during the reaction into a mixture of zinc chloride and hydrogen cyanide. Zinc chloride has already been shown by Gattermann to be an effective condensing agent for the reaction of the hydrogen cyanide with certain phenols in the presence of hydrogen chloride. The laboratory results have fully met the expectations. Very satisfactory yields have been obtained with resorcinol, α -naphthol, β -naphthol, or cinol and pyrogallol; in fact, the yields were similar to those obtained with anhydrous hydrogen cyanide. Undoubtedly any phenol that can be converted to an hydroxy aldehyde using the directions of Gattermann can be converted to an hydroxy aldehyde equally well by this slight but most convenient modification.

The preparation of zinc cyanide suitable for use in the reaction described above proved to be a problem in itself. Up to the present time zinc cyanide free from zinc oxycyanide has been made by the action of hydrogen cyanide upon zinc oxide or by other methods entirely unfitted for the present problem, the success of which depends upon the ease of preparation of the zinc cyanide. An easy method for preparing a satisfactory zinc cyanide for the Gattermann reaction was finally found. It consisted in treating an aqueous solution of sodium cyanide with magnesium chloride in order to precipitate the impurities of sodium hydroxide and sodium carbonate. Zinc cyanide was then precipitated by adding to the solution a molecularly equivalent amount of zinc chloride in alcohol. The product obtained is about 90% zinc cyanide and contains no impurity that interferes with the Gattermann synthesis.

 $^{^{3}}$ (a) Ziegler, Ber., 54B, 110 (1921). (b) Johnson and Lane, This Journal, 43, 354 (1921).

⁴ Karrer, Helvetica Chim. Acta, 2, 89 (1919).

The literature reports that zinc cyanide gradually decomposes on standing. The product made as described, if kept in a dry atmosphere, apparently decomposes only very slowly. After several weeks it was analyzed and showed a depreciation of about 2%. Nevertheless, it gave just as satisfactory results as when first prepared. No extensive experiments were made to determine just how long the zinc cyanide could be kept, since it can be so easily and quickly prepared.

Gattermann has also described the preparation of aldehydes from phenol ethers by the action of hydrogen chloride, hydrogen cyanide and anhydrous aluminum chloride on phenol ethers. Moreover, he has shown that certain hydroxy aldehydes which could not be made by the direct condensation of the phenol with hydrogen cyanide, hydrogen chloride and zinc chloride could be formed by the action of hydrogen chloride, hydrogen cyanide and anhydrous aluminum chloride upon the phenol. A modification of these last processes in such a way as to avoid the anhydrous hydrogen cyanide has proved successful and is now being studied in detail.

The authors are indebted to Dr. J. H. Reedy for suggestions in connection with the purification of the zinc cyanide.

Experimental Part

Zinc Cyanide.—To a 5% excess over 1 molecular equivalent of technical sodium cyanide calculated as 100% pure, regardless of its purity, dissolved in about 25% more than an equal weight of water, was added magnesium chloride solution until no more precipitate of magnesium hydroxide and carbonate formed (this requires an amount of magnesium chloride sufficient to precipitate a quantity of sodium carbonate equal in weight to about 7-8% of the sodium cyanide used). The precipitate was filtered off immediately and the filtrate added at once to 1 molecular equivalent of zinc chloride dissolved in as small an amount as possible of 50% alcohol. The zinc cyanide precipitated and was filtered off. When the magnesium hydroxide and carbonate were not removed immediately and the zinc cyanide precipitated at once, the reaction mixture turned dark until finally it became almost black. When the zinc chloride was added to such a colored solution the zinc cyanide formed was always colored. The zinc cyanide was washed on the filter with alcohol, then with ether and dried in a desiccator or in an airbath at 50° .

The only important precaution in this preparation is to insure an excess of zinc chloride over sodium cyanide. If the sodium cyanide is in excess, the zinc cyanide invariably precipitates as a sticky mass which is difficult to filter and unsatisfactory for the preparation of the hydroxy aldehydes.

The product was analyzed for the amount of cyanide present by titrating it with standardized silver nitrate solution, and was shown to be about 90% pure zinc cyanide. The remaining 10% was presumably for the most part sodium chloride, with small amounts of zinc chloride, magnesium chloride and perhaps traces of basic zinc cyanide. These do not interfere with the Gattermann reaction.

General Method of Preparation of the Hydroxy Aldehydes.—A 500cc. wide-mouth bottle was fitted with a stopper holding an efficient mechanical stirrer with a mercury seal, a reflux water condenser and an inlet tube, with wide mouth to prevent clogging from the precipitate, ex-

tending nearly to the bottom of the bottle. To this inlet tube was attached a safety bottle and to this a generator producing dry hydrogen chloride. To the top of the condenser was connected a tube leading into a wash bottle containing sulfuric acid; from this a tube was led to a safety bottle and from the latter a tube to the surface of a sodium hydroxide solution.

In the reaction bottle was placed 20 g, of the hydroxy compound in 150 to 200 cc. of dry ether. Sufficient dry zinc cyanide was then added, equivalent to 1.5 mol. for every mol. of phenol. The mechanical stirrer was started and dry hydrogen chloride was passed in rapidly. The zinc cyanide gradually disappeared with the formation of a milky solution (the milkiness being probably due to the sodium chloride present) and as more and more hydrogen chloride dissolved, the imide hydrochloride condensation product began to separate as a thick oil. In 10 to 30 minutes this oil turned to a solid. At the end of about 1.5 hours the ether was usually saturated with hydrogen chloride. When this point was reached, the stream of gas was passed in more slowly and stirring was continued for $^{1}/_{2}$ hour longer to be certain that all the phenol had reacted. The ether was decanted from the solid material and the imide hydrochloride then decomposed with water or dil. alcohol as described below.

The amount of ether used in the above reaction was somewhat greater than that suggested by Gattermann. It was found, however, that the colored by-products which invariably formed with these phenolic compounds were smaller in amount the larger the amount of solvent.

It was also possible to use dry chloroform in place of dry ether. Under these conditions the reaction went practically the same, but the crude products were somewhat more colored.

Resorcyl Aldehyde.—With resorcinol the reaction mixture turned pink and the solid material tended to be pink. Previous investigators advised the decomposition of the imide hydrochloride by boiling it with water for about 5 minutes and then allowing the product to cool. It was found that by this procedure the resorcyl aldehyde which separated amounted to about 70% of the calculated amount. It was found to be much more satisfactory to add about 100 cc. of water to the imide hydrochloride, raise the solution to the boiling point, filter the mixture and then immediately allow the filtrate to cool. In this way about a 50% yield of aldehyde was obtained. This was filtered and the filtrate was allowed to stand. In about 10 to 15 hours, more material separated which, upon filtration, amounted to about 45% of the calculated yield, giving a combined yield of 95%.

The resorcyl aldehyde obtained had only the slightest tinge of color and melted very sharply at 135–136° (Gattermann, 136°). By recrystallization from water with the addition of boneblack, a product absolutely free from traces of colored by-products was produced.

Orcinol Aldehyde.—The orcinol used in these experiments must be thoroughly dried to remove the water of crystallization which is ordinarily present. The reaction proceeded smoothly with the development of a pink color. No special precaution was necessary in the decomposition of the imide hydrochloride. It was merely boiled for

two to three minutes with 100 cc. of water, filtered and allowed to cool. The yield of product was about 85%; m. p., 178–180° (Gattermann, 180°). By a crystallization from water with the addition of boneblack a very pure product was obtained.

 β -Naphthol Aldehyde.—The imide hydrochloride was decomposed by boiling it with 100 cc. of water and an 85% yield of product was obtained, melting a few degrees below the correct point. After recrystallization from water with the addition of bone-black, a very pure product melting at 80–81° (Gattermann, 81°) was obtained.

 α -Naphthol Aldehyde.—In contrast to the hydroxy compounds described above where the reaction mixture was pink, that from α -naphthol became deep yellow. The imide hydrochloride was decomposed by boiling it with 700 cc. of 30% alcohol until complete solution took place; then the solution was filtered and allowed to cool. When water was used in this experiment, the α -naphthol aldehyde, because of its insolubility in water, tended to separate immediately and to prevent the smooth and complete decomposition of the imide hydrochloride. The product obtained as described formed in 72% yield and melted slightly low. More aldehyde could be recovered from the mother liquor. By recrystallization from water or 30% alcohol with added boneblack a very pure product resulted; m. p., 178° (Gattermann, 180°).

Pyrogallol Aldehyde.—The ether in the reaction mixture turned more deeply colored than when the other phenols were used, but the imide hydrochloride was light colored. It was decomposed by boiling it for two to three minutes with 400 cc. of water. The yield was about 45%, and the product melted at 158° (Gattermann, 158°). It can be obtained very pure by recrystallization from water containing boneblack.

Summary

- 1. Gattermann found that certain types of phenols condensed with hydrogen chloride, hydrogen cyanide and anhydrous zinc chloride to give compounds that hydrolyzed readily to form hydroxy aldehydes. A description of a method is given by which these same aldehydes can be formed in the same yields as found by Gattermann, but zinc cyanide is substituted for the anhydrous zinc chloride and hydrogen cyanide that he used.
- 2. Anhydrous zinc cyanide for this reaction was produced by treating aqueous sodium cyanide with magnesium chloride to precipitate the impurities of carbonate and hydroxide, filtering the precipitate and adding alcoholic zinc chloride to the filtrate.

THE DETECTION OF PENTOSE, FORMALDEHYDE AND METHYL ALCOHOL

By James B. Sumner Received May 25, 1923

I have recently attempted to improve the well-known Bial's reagent¹ for pentoses so that it will keep, and have found that when the 6 g. of orcinol and 40 drops of 10% ferric chloride solution are dissolved together in 200 cc. of ethyl alcohol without the addition of hydrochloric acid, the solution is stable. Fifteen drops of this alcoholic solution, 5 cc. of the sugar solution and an equal volume of fuming hydrochloric acid are mixed and heated in boiling water. A clear blue color always develops when 1 mg. of arabinose or xylose is present. When more pentose is present a precipitate quickly forms. With less than 1 mg. the color is greenish. When considerable quantities of hexoses obscure the test the precipitate can be filtered off, washed with water and dissolved in alcohol, when some green color will be observed if the proportion of hexose to pentose is not too great. The absorption band is between the C and D lines.

While testing the specificity of this reagent I have found that it gives interesting results with formaldehyde. With 2 mg. of formaldehyde in 2 cc. of water, 10 drops of the orcinol solution and 2 cc. of concd. hydrochloric acid cause the immediate formation of a white precipitate, consisting of very small spheroids. With only 0.2 mg. of formaldehyde the precipitate does not appear for several minutes. Heating hastens its appearance. With still lower concentrations of formaldehyde no precipitate is formed and the solution becomes yellow upon heating. Acetaldehyde gives a similar precipitate with orcinol, but when a sufficient amount of water is present and the material is heated at once, no precipitate is formed unless a very large amount of acetaldehyde is present and the inside of the test-tube is covered with scratches.

When the material in the test with formaldehyde is heated for 15 minutes in boiling water, the precipitate turns brown and the addition of an excess of alkali causes it to dissolve to a pink solution, or if a large amount of precipitate was present, pink flocks will be formed. The precipitate formed by acetaldehyde does not turn brown upon heating and the addition of an excess of alkali causes it to dissolve to form a yellow solution.

With quantities of formaldehyde smaller than 0.1 mg., where there is no precipitate upon heating for 15 or 20 minutes, the addition of an excess of sodium hydroxide produces a pink or salmon color with an intense green fluorescence. So intense is this fluorescence that the test will readily

¹ Hawk, "Physiological Chemistry," Blakiston, 1923, 8th edition, 644.

show one part of formaldehyde in ten million parts of water. Acetaldehyde treated in the same manner gives a solution that shows no fluorescence at all.

Instead of heating with hydrochloric acid, the test can be heated directly with sodium hydroxide, but carried out in this manner is somewhat less delicate.

Another way of testing for the presence of formaldehyde is to add a few drops of an alcoholic solution of orcinol, omitting the ferric chloride, and 2 drops of 20% sodium hydroxide solution. The solution soon becomes pink when formaldehyde is present, owing to oxidation by atmospheric oxygen, the formaldehyde probably acting as an oxydase. As little as one part of formaldehyde in one million of water can be detected in this manner, but only if interfering substances are absent. Traces of copper also produce a pink color, and acetaldehyde causes the appearance of a greenishyellow color. Orcinol alone in the presence of alkali slowly develops a pink color.

While the production of the green fluorescence appeared to be too delicate to be put to use for the detection of methyl alcohol (after its oxidation to formaldehyde), the production of the white precipitate seemed suitable. I have found that this reaction can readily be used, and that its use is limited chiefly by the process employed to oxidize the alcohol. The application of a red hot copper spiral produces a very considerable amount of formaldehyde from pure ethyl alcohol. Using this procedure it is difficult to distinguish between pure ethyl alcohol and ethyl alcohol containing 1% of methyl alcohol.

Gettler² in his excellent review of 58 tests for the detection of methyl alcohol has recommended potassium dichromate and sulfuric acid as an oxidizing agent that forms very little formaldehyde from ethyl alcohol. I have tried this means of oxidizing the alcohols and have found it to be extremely satisfactory. As applied to the new method, removal of the chromium and sulfuric acid is not necessary, nor is it necessary to separate the acetaldehyde from the formaldehyde by fractional distillation. However, it is advisable to expel some of the acetaldehyde by heating in a large test-tube in boiling water, as acetaldehyde in large amounts sometimes forms a precipitate with orcinol. This seems to be due to the use of scratched test-tubes or test-tubes that have been attacked by hot phosphoric acid. The test-tubes must not be too narrow or the acetaldehyde will have difficulty in escaping. The amount of alcohol used in the test is 9 times greater than the quantity theoretically necessary to reduce all of the dichromate. An aqueous 0.5% solution of orcinol is used, and the addition of ferric chloride omitted.

The procedure is as follows.

² Gettler, J. Biol. Chem., 42, 311 (1920).

Place in a large test-tube which is 22 mm in diameter and free from scratches, 1 cc. of the suspected alcohol, 2 cc. of 6.7% potassium dichromate solution and 2 cc. of 1:2 (62%) sulfuric acid. Mix at once after adding the sulfuric acid and allow to stand at room temperature for about 10 minutes. The reduction of the chromic acid to blue chromic sulfate should take about 40 seconds, and if it takes much longer than this the alcohol used contains too much water. Add 15 cc. of distilled water, mix thoroughly and heat in boiling water for 10 minutes. Now add 5 mg. of orcinol in 1 cc. of water, mix very thoroughly and heat in boiling water for 30 minutes. If the alcohol contained 5% or more of methyl alcohol, a precipitate will be formed after about 5 minutes heating. With 1% of methyl alcohol a precipitate will form after 15 minutes' heating. The test will show methyl alcohol down to 0.5%, although in this case it may be necessary to heat for 30 minutes and then allow the solution to cool before a precipitate forms. If the precipitate is filtered off it will be seen to be distinctly brown or yellow.

Quantities of methyl alcohol smaller than 0.5% can be detected by precipitating the chromium by adding a slight excess of sodium hydroxide and heating. When this is filtered, the clear filtrate possesses a green fluorescence if even traces of methyl alcohol were originally present. This last procedure is of doubtful value, as it is to be expected that traces of methyl alcohol derived from pectinous substances may possibly be present in beverages from fruits.

The alcohol used in the test is obtained by distilling the suspected solution or beverage, using a Vigreux column to obtain as complete a separation from the water as possible. The temperature of the upper portion of the column should not be allowed to exceed 80°.

Formic acid, amyl alcohol, acetone and furfurol do not interfere with the test. Glycerol does not interfere because it is eliminated in the process of distillation; but if added to the alcoholic distillate glycerol gives a positive test if as much as 5 mg. is present. I believe, therefore, that the procedure for the detection of methyl alcohol can be used also for the detection of small amounts of glycerol. It is impossible at the present time to say that there are found in alcoholic beverages no substances capable of interfering with the detection of methyl alcohol as carried out by this method, but I have as yet found none and believe the method to be more time saving and more trustworthy than other chemical tests that have been proposed in such large numbers for the identification of methyl alcohol in alcoholic beverages.

Summary

- 1. A new method is proposed for using Bial's test for pentoses.
- 2. An extremely delicate test for formaldehyde is described.
- 3. A new method is given for the detection of methyl alcohol in alcoholic beverages.

FLUORO-ACETYL DERIVATIVES OF SUGARS. II. OPTICAL ROTATION AND ATOMIC DIMENSION

By D. H. Brauns Received May 28, 1923

Introduction

Since the well-known discovery by Le Bel and van't Hoff of the coincidence of the presence of an asymmetric carbon atom in the molecule and the action of the latter on the plane of polarized light, organic and physical chemists have diligently studied this phenomenon. This marked interest has undoubtedly been inspired by the hope that this relation, coupled with ability to synthesize organic compounds of desired structure, would permit a further insight into the subject.

It is noteworthy that in proportion to the efforts made, the results are rather small. Van't Hoff's principle of optical superposition has given interesting results in the hands of Hudson^{2a} and Levene. ^{2b} The application of this principle and other related rules established by these authors are especially useful for determining the structure of organic compounds containing asymmetric carbon atoms. Nevertheless, the isolated and uncorrelated position of the property of optical rotation among other physical constants was not changed by these and numerous other investigations in which the influence of concentration of the solute, temperature, nature of the solvent and (most successfully) the wave length of the light (dispersion) were studied.3 It has been pointed out4 that the theory of Drude forms the basis for arranging and combining the facts regarding rotatory dispersion. A theory by Livens⁵ based on a general theory by H. A. Lorentz, establishing a relation between the optical rotation and the refractive index, is also regarded as promising for development. Inasmuch, however, as these theories have a purely physical basis without introducing a chemical viewpoint, it would appear that they are not capable of yielding a workable method for experimental treatment of the subject in its general form.6 This objection does not, however, hold for the

theory of Guye (at least in its restricted form) which is an attempt to correlate the rotation and the difference in weight of the 4 asymmetric groups, without taking into account the distance of these groups from the center of gravity of the molecule. In its restricted form, the theory of Guye has been extensively tested by many organic chemists, the results disproving the validity of the theory.⁷

Theoretical Discussion

Notwithstanding these results, it seemed worth while to continue the search for some relation between the optical rotation and the weights of the asymmetric groups. Whereas former investigators changed an asymmetric group to a next higher one of the same homologous series and compared the rotations of the resulting derivatives, it appeared simpler to compare the rotations of derivatives which differ only in having an asymmetric halogen replaced by another halogen. With this type of derivatives the influence of the length of the chain may be eliminated. Furthermore, it is an important fact that the affinity of the halogens for hydrogen and oxygen changes regularly when they are compared successively according to their position in Mendeleieff's table; in addition to the direct union of the halogen with the carbon atom, secondary bonds to hydrogen and oxygen must also be taken into account. Since the influence of these affinities varies gradually and in a regular manner in the halogen series and only single atoms are considered, we may suppose that the position which the halogen occupies in the molecule is not changed when one halogen is replaced by another. Indeed, by comparing the optical rotations of chloro-, bromo- and iodo-tetra-acetylglucose, it was found that the increase in rotation is proportional to the increase in atomic weight. The data are compared in Table II, together with those for the analogous cellose derivatives. The fundamental thought of Guye, that the difference in weight of the asymmetric groups determines the rotation, so far as these data are concerned, is therefore supported by a comparison between the atomic weights and molecular rotations. It is evident, however, that a better agreement is obtained in the case of the specific rotations. It seemed worth while to extend this relation by preparing the analogous fluorine derivatives and including their values in the comparison. The preparation of the fluoro-acetyl derivatives of glucose, xylose and cellose and the determination of their specific rotations have been described by the author.8 Of the other fluoro-acetyl derivatives of sugars, which have been subsequently prepared, fluorotetra-acetylfructose will also be considered in this relation, inasmuch as the author has succeeded in preparing the corresponding bromotetra-acetylfructose in crystalline condition

 ⁷ H. Landolt, "Das optische Drehungsvermögen organischer Substanzen," Vieweg, Braunschweig, 2nd ed., 1898, p. 268. Also Tschugaeff, Ber., 31, 360, 1775, 2451 (1898).
 ⁸ Brauns, This Journal, 45, 833 (1923).

(see experimental part). Chlorotetra-acetylfructose has been previously9 prepared.

The results of comparison of the fluoro, chloro, bromo and iodo derivatives are presented in Table II, which shows that the data agree with the results of previous investigators in failing to support Guye's hypothesis. The increase in rotation from the fluorine to the chlorine derivative is much greater than the other differences, whereas the increase in atomic weight from fluorine to chlorine is much smaller than the others. The deviations found here immediately suggest a relationship with the atomic diameters. W. L. Bragg¹¹ derived these from the distances of the alternating atoms in the cubical crystals of the alkali halides. Bragg found that "the substitution of chlorine by bromine or bromine by iodine increases the distances between atomic centers by an amount which is approximately the same throughout the series of compounds, as the figures in italics show." Table I shows the results of Bragg's investigation.

Table I^{12} Interatomic Distances in Halides, in Ångstrom Units (10^{-8} cm.)

		United with-	
	Na	K	Rb
F	2.39	2.73	
	.42	.40	
Cl	2.81	3.13	3.28 °
	.16	.15	.16
Br	2.97	3.28	3.44
	. 26	.24	.22
I	3.23	3.52	3.66

For convenience we will take as an average for these increases 41, 16, and 24×10^{-10} cm. These values have been compared with the increase in optical rotation from the fluorine to the chlorine derivatives, etc., in Tables III and IV; the last column of Table III shows the differences

⁹ This Journal, 42, 1846 (1920).

¹⁰ In addition to fluorotetra-acetylfructose and the fluoro-acetyl sugar derivatives previously described (This Journal, 45, 833 (1923)) the author has prepared other fluoro-acetyl derivatives of other sugars; however, in the case of these latter derivatives, the other halogen derivatives necessary for comparison are not available. The preparation and properties of these latter fluorine derivatives will be reported later.

¹¹ Bragg, Science Progress, 16, 45 (1921).

¹² These figures are dimensions of ions, which have the outer shell of electrons complete, as in the case of the inert gases. No doubt these figures are equally applicable for the dimensions of the neutral atoms of the halogens. It is realized that these values are not final, nor do they agree exactly with those determined by other workers using different methods or holding different theories of atomic arrangement or structure. However, there seems to be no expectation, from the writings of many workers along this line, that it will be found that these values are not approximately correct. Even a critic of Bragg's views [Wyckoff, Proc. Nat. Acad. Sci., 9, 33–8 (1923)] gives values for the diameters of F, Cl, Br and I the differences between which are in the ratio of 41: 15:23, that is, not materially different from those adopted in this paper.

in atomic dimensions, reduced to approximately the same numerical values as those of the preceding columns.

The following conclusions are derived from examination of these tables.

- 1. The differences in specific rotations vary in parallel manner with the differences in atomic diameters. Whereas the differences themselves are for the heavier cellose derivatives smaller and for the lighter xylose derivatives larger than for the glucose derivatives, they are nevertheless in all cases approximately proportional to the differences of the atomic diameters.
 - 2. Atomic dimensions may well play a role in physical constants

^b Starting with the (F-Cl) rotation-difference for each sugar the other values given are to one another as 41:16:24 (Table I).

pertaining to volume (specific gravity, solubility, refraction, etc.) as A. Sommerfeld ¹³ suggests. In the case of optical rotation, however, the relationship is less apparent. We may suppose that the distance between the halogen and the carbon atom is the determining factor; in this case it is strange, however, that the atomic weight is not more directly involved. It may be that the atomic dimension is an expression of the rotational momentum of the moving electrons in the atom. Unexpected is the result that the specific and not the molecular rotation is related to the atomic diameter in this simple way. After all, the nature of the action of a molecule on the light still remains to be determined. We have probably to interpret the results by supposing that the dimension of the halogen atom combined with the dimensions of the other asymmetric groups determines the asymmetric character of the molecule, and that the molecule by its entire weight (or with its total number of positive and negative electrons) brings its asymmetry to act upon the light.

Other relations in which atomic dimensions seem to play a role were observed by examination of the literature. In Tables V, VI and VII the author has inserted the values of the atomic diameter for purpose of comparison with the data quoted.

Chemical Affinity or Reaction Velocity

Holleman¹⁴ and co-workers determined quantitatively the amounts of 15 o- and p-nitrohalogenbenzene which are formed by nitrating monohalogenbenzene. The results are given in Table V.

Table V

Comparison of Atomic Diameter and the Formation of Nitrohalogenbenzenes

I	41.1	58.7	3.0	.70			

It is remarkable that the difference F-Cl is again much larger than Cl-Br. This suggests a relation to atomic dimensions. The difference Br-I does not agree with this assumption; the investigation of these iodine derivatives may, however, be subject to error owing to the possibility of secondary

¹³ Sommerfeld, "Atombau und Spektrallinien," 3rd ed., 1922, Vieweg (Braunschweig) p. 132.

¹⁵ The meta compound is produced only in traces.

reactions. Results of Lulofs¹⁶ who investigated a somewhat similar subject, measuring the velocity of substitution of halogen by an oxyalkyl group in halogen dinitrobenzenes, appear also to indicate that Holleman's results may be complicated by secondary reactions. Lulofs found the respective values 3.26, 1.89 and 0.455 for the chlorine, bromine and iodine derivatives; his data show for the difference Br-I a slightly greater value than for Cl-Br.

Boiling Points and Molecular Volumes of Corresponding Halogen Derivatives

Beekman¹⁷ determined the boiling points of the members of a series of corresponding halogen derivatives. Most of the molecular volumes were determined by interpolation from existing data and are, therefore, according to the author, only approximately correct. His results are compared with atomic dimensions in Table VI.

Table VI

Differences in Boiling Points and Molecular Volumes of Halogen Derivatives

		•	
30.6	8.2	30.6	8.2
20.9	4.25	13.0	3.2
23.5	8.1	17.9	4.8
Para I	Derivatives		
37	8.61	37	8.6
14	4.93	13	3.4
			· · · ·
• 14	6.89		5.0
	25.1 31.76 Meta I 30.6 20.9 23.5	25.1 3.68 31.76 6.04 Meta Derivatives 30.6 8.2 20.9 4.25 23.5 8.1 Para Derivatives 37 8.61 14 4.93	25.1 3.68 18.1 31.76 6.04 27.2 Meta Derivatives 30.6 8.2 30.6 20.9 4.25 13.0 23.5 8.1 17.9 Para Derivatives 37 8.61 37 14 4.93 13

The agreement with difference in atomic diameters is better for the boiling points than for the molecular volumes. Both values show, however, the exceptional place taken by the fluorine derivatives, as Beekman has already observed.

¹⁷ Beekman, Rec. trav. chim., 23, 144 (1904).

Atomic Refraction

Swarts¹⁸ has determined the atomic refraction of several saturated and unsaturated compounds containing fluorine, chlorine and bromine. Table VII shows the results of this investigation, the numerical values of the atomic dimensions being reduced.

TABLE VII

Сомра	rison of Atom		ion Indici	es with A	TOMIC DIA	METERS
	Sat. compds.	Unsat. compds.	D	iffs.	Diff. at	
F	1.082	0.775				
			4.8	5.2	4.8	5.2
CI	5.9028	6.001				
			2.8	2.7	1.9	2.0
Br	8.762	8.759				

The agreement is not very striking, but shows that the difference in atomic refraction for Cl-F is nearly twice as great as for Br-Cl. 19

As has already been observed, the correlation of molecular volume and refraction with atomic dimension is not unexpected. Furthermore, the relative quantities of *ortho* and *para* derivatives which are formed in a reaction can be conceived to be dependent upon the atomic dimension (in this case, the influence of the distance of the halogen from the carbon atom). The relationship of specific rotation and atomic dimension suggests, however, the possibility that atomic dimension may also play an important role in a number of physical and chemical properties which are not supposed to be influenced by this factor.²⁰

18 Bull. acad. roy. med. Belg., [3] 34, 293 (1897).

Heydweiller [Ber. physik. Ges., 16, 722 (1914)] has compiled the atomic-refraction data for nearly all elements existing in solution in ionized condition. The values for the halogens (values for F and Cl are not very accurate) give the ratio (Cl-F):(Br-Cl): I-Br)=5.6:3.5:5.9, which shows that the (I-Br) value is decidedly too high for the atomic dimension relationship. It is possible that some complicating factor is involved.

While this paper was in the hands of the reviewing committee, another paper by Swarts has come to the writer's attention [J. chim. phys., 20, 30 (1923)] in which comparisons are made between atomic refraction and the same atomic-diameter values taken from Bragg which have been used in the present paper. Swarts found almost exact agreement in the case of the three heavier halogens, although fluorine showed considerable deviation.

²⁰ The investigation of optical rotation from this point of view will be continued for other types of halogen derivatives; such derivatives, representing four different sugar groups,—an aldohexose, a pentose, a disaccharide, and a ketose,—have already been tested. It is probable that further investigation will throw more light on the specific influence of the medium, concentration, etc., on the optical rotation; in the case of the sugar derivatives discussed in the present paper this influence is, however, relatively small as compared with the large differences in specific rotation. Other groups of related elements, such as (oxygen), sulfur, selenium and tellurium, may be examined in view of the fact that methods for obtaining corresponding sugar derivatives containing these elements (S and Se) are available. The derivatives already reported [Schneider and coworkers, Ber., 52, 2135 (1920), Wrede, Z. physiol. Chem., 115, 284 (1921), and many others of earlier date] do not permit a comparison.

Experimental Part

Fluorotetra-acetylfructose.—Starting with β -penta-acetylfructose²¹ the manner of preparation of this compound is the same as that described by the author for fluorotetraacetylglucose.³ The resulting colorless sirup crystallized readily when stirred with petroleun ether. Ten g. of β -penta-acetylfructose yielded about 7 g. of impure product. It was recrystallized by dissolving in 30 cc. of hot, 95% alcohol, filtering and washing the filter with about 15 cc. of hot alcohol. Crystals of moderate size were obtained; yield of pure substance, about 5 g.; m. p., 112°. A second and third recrystallization gave practically identical specific rotations. After the second recrystallization, 1.4803 g. made up to 25 cc. in chloroform produced a rotation in a 2dm. tube of 10.709 circular degrees to the left; hence, $[\alpha]_D^{20} = -90.43^\circ$. The compound is stable, colorless, odorless, and has a bitter taste; it is very slightly soluble in petroleum ether, slightly soluble in alcohol, and readily soluble in chloroform.

Analyses. Subs., 0.2151: CO₂, 0.3783; H₂O, 0.1046. Subs., 0.5819: CaF₂, 0.0620. Subs., 0.5378: 219.3 cc. of 0.1 N NaOH; 142.39 cc. of 0.1 N H₂SO₄. Subs., 1.8670, 3.6201, 5.1018: C₆H₆, 100; ΔF , 0.276°, 0.215°, 0.728°. Calc. for C₁₄H₁₉Q₉F: C, 47.98; H, 5.47; F, 5.43; 68.60 cc. of 0.1 N NaOH for AcOH; mol. wt., 350. Found: C, 47.97; H, 5.44; F, 5.19; 68.32 cc. of 0.1 N NaOH; mol. wt., 338, 347, 350.

Bromotetra-acetylfructose.—The preparation of this compound requires much care. At ordinary temperature it decomposes quickly, and special arrangements were required for analyzing and measuring the optical rotation of the pure substance. On account of the theoretical considerations involved, the attempt to prepare it which had been unsuccessfully made on previous occasions was resumed and finally led to the preparation of the pure crystalline substance and measurement of its rotation, as the excellent figures obtained on analysis show.

Six g. of powdered β-penta-acetylfructose was dissolved in 7 cc. of glacial acetic acid in a 25cc. volumetric flask with accurately ground stopper, by slightly warming the mixture on the steam-bath, the solution being then cooled in cracked ice to about 0°. A saturated solution of hydrogen bromide in glacial acetic acid was cooled in an ice-and-salt bath in a tube with ground stopper. This cold solution was used for quickly completing the volume of the fructose penta-acetate solution to about 25 cc., after which the stopper of the volumetric flask was replaced and the sirupy contents mixed by rotating the flask, the latter being kept in cracked ice for one hour. The solution was poured into about 30 cc. of chloroform²³ which had been cooled in an ice-and-salt bath in an Erlenmeyer flask with ground stopper. Without rinsing out the volumetric flask, the chloroform solution was poured in a mixture of ice water, cracked ice and a small amount of chloroform, contained in a separatory funnel.²⁴ The mixture was shaken and the chloroform solution drawn off into another separatory funnel and again shaken. This procedure was repeated twice, washing being omitted in order to permit more rapid work. The chloroform solution was dried over anhydrous sodium sulfate in an Erlenmeyer

²¹ This Journal, 37, 1283 (1915).

 $^{^{22}}$ For description of methods of analysis, see Ref. 8, p. 835. Saponification was performed by shaking with NaOH solution for $8^1/_2$ hours at 0° and titrating with $\rm H_2SO_4$ and phenolphthalein.

²³ The CHCl₃ had been specially purified by shaking it with some water, drying over Na₂SO₄, and distilling, the first and last fractions of the distillate being discarded.

²⁴ Two separatory funnels were made ready in this manner before the preparation of the compound was commenced. Arrangements for the Carius and acetyl determinations and for combustion were also made in advance, the only subsequent manipulation required being the introduction of the weighed substance.

flask (with ground stopper) in an ice-and-salt bath. After drying for about \$1/4\$ hour, the solution was filtered into a crystallizing dish and evaporated under a glass jar by means of a rapid current of air. The solution was cooled below \$0^{\circ}\$ by this rapid evaporation. A pure white crystalline preparation was obtained.\$25\$ A few cubic centimeters of absolute ether were stirred with the crystals and they were then pressed between hardened paper. The yield was more than \$4\$ g. of pure substance. Taking into account the manner of preparation, the reaction probably gives a quantitative yield. The \$4\$ accurate weighings necessary for combustion, Carius determination (including scaling of tube), acetyl determination, and preparation of the chloroform solution for measurement of optical rotation (performed in order stated), were made in about 25 minutes and gave the following results.

Analyses. Subs., 0.1614: CO₂, 0.2419; H₂O, 0.0685. Subs., 0.1885; AgBr, 0.0864. Subs., 0.5522: 219.3 cc. of 0.1 N NaOH; 152.4 cc. 0.1 N H₂SO₄; AgBr, 0.2518. Calc. for $C_{14}H_{19}O_{9}Br$: C, 40.87; H, 4.66; Br, 19.44; 152.6 cc. of 0.1 N H₂SO₄; AgBr, 0.2518. Found: C, 40.89; H, 4.75; Br, 19.50; 152.4 cc. of 0.1 N H₂SO₄; AgBr, 0.2518.

A solution of 0.4768 g. in chloroform made up to 25 cc. about 25 minutes after the preparation was obtained, produced a rotation in a 2dm. tube of 7.070 circular degrees to the left; hence, $[\alpha]_D^{20} = -186^{\circ}$. Another preparation of bromotetra-acetylfructose was examined immediately after the substance was prepared. A solution of 0.8188 g. of this preparation in 25 cc. of chloroform produced a rotation in a 2dm. tube of 12.397 circular degrees to the left; hence, $[\alpha]_D^{20} = -189.1^{\circ}$; this is taken as the specific rotation of the pure substance.

The substance was quickly recrystallized by making a saturated solution in pure ether in a weighing bottle, seeding with a few crystals, closing tightly with a rubber stopper and cooling in an ice-and-salt bath. The beautiful, large crystals which separated were quickly pressed between hardened filter paper. The specific rotation of this preparation was $[\alpha]_D^{20}$ —188.3°.

Bromotetra-acetylfructose is a very unstable substance. It can be obtained in pure crystalline form, but decomposition is already noticeable at room temperature after 25 minutes. In a few hours most of it is converted into β -tetra-acetylfructose. It may be kept in a pure ether solution, or better a pure chloroform solution, at -10° overnight, but decomposition is noticeable even under these conditions. The melting point is 65°. It is colorless, odorless, has a bitter taste, and is very soluble in the usual solvents and slightly soluble in petroleum ether.

Summary

In comparing the optical rotations of monohalogen acetyl derivatives of glucose, cellose, xylose and fructose, the differences F-Cl, Cl-Br, and Br-I are found to be approximately proportional to the differences in atomic diameter recorded by Bragg. It is remarkable that this simple relation holds for the specific but not for the molecular rotation. The

²⁵ While the chloroform solution was being evaporated to a thick colorless sirup (requiring about one hour), a small portion of the solution was evaporated on a watch glass, and by rubbing with a glass rod and finally adding ether or petroleum ether and subsequently evaporating, the resulting sirup was brought to crystallization. The crystals obtained were used for seeding the principal portion of the chloroform-free sirup.

method of preparation, properties, and analyses of fluorotetra-acetyl-fructose and bromotetra-acetyl-fructose are given.

THE PREPARATION AND PROPERTIES OF 1-MERCAPTO-BENZOTHIAZOLE, ITS HOMOLOGS AND DERIVATIVES^{1,2}

By L. B. Sebrell and C. E. Boord

RECEIVED JUNE 2, 1923

The present paper comprises a study of the synthesis of 1-mercaptobenzothiazole and its derivatives which was made in connection with an investigation of the role played by these compounds when functioning as accelerators of vulcanization. Eight different mercapto-benzothiazoles were prepared and studied. Each of these substances excepting where the quantity of material was limited, were prepared by four separate methods. These methods were alike in that the reaction mixture was heated in an autoclave under pressure. The reaction mixtures were as follows: (1) the corresponding disubstituted thio-urea and sulfur; (2) the zinc salt of the corresponding aryl dithiocarbamic acid and sulfur; (3) the ammonium salt of the same acid and sulfur; (4) a mixture of the corresponding aryl amine, carbon disulfide and sulfur.

The first method has been described by Romani.³ The last three methods are new.

¹ This paper and one entitled: "A Study of 1-Mercapto-benzothiazole and its Derivatives as Accelerators of Vulcanization" being published in a current number of *J. Ind. Eng. Chem.* [15, 1009 (1923)] have been abstracted from the dissertation presented by L. B. Sebrell to the Graduate School of Ohio State University in partial fulfilment of the requirements for the degree of Doctor of Philosophy, September, 1922.

² The system of nomenclature as outlined in \hat{C} . A. Decennial Index, 1-10, 2345, namely, omitting the sulfur and beginning the numbering with the carbon atom of the thiazole ring has been followed throughout this article.

³ The four methods of preparation described in the following pages as applied to 1-mercapto-benzothiazole and its three monomethyl derivatives, together with their disulfides and metallic salts were reported before the Organic Division of the American Chemical Society at the Birmingham meeting, April 6th, 1922. [(a) See Science, 56, 55 (1922).] Shortly afterward, an article by Romani, [(b) Gazz. chim. ital., 52, 29 (1922)] became available, describing the preparation of the three methyl derivatives by one of the methods, namely, heating the corresponding disubstituted thio-urea with sulfur. To him, undoubtedly, belongs priority of publication of a description of these three derivatives by this one method. He did not describe the disulfides.

Historical

1-Mercapto-benzothiazole was first obtained by A. W. Hofmann⁴ in an attempt to prepare the disulfilydryl derivative of thiocarbanilide by the action of carbon disulfide on o-aminophenol. He obtained the same substance by the action of sodium hydrosulfide on chlorophenyl mustard oil (1-chloro-benzothiazole) and also when carbon disulfide was caused to react with o-aminothiophenol disulfide. The product thus obtained, after recrystallization from alcohol, melted at 179° and was easily oxidized to a disulfide melting at 180°.

Jacobson and Frankenbacher⁵ while studying the formation of benzothiazoles, heated azobenzene with carbon disulfide in a sealed tube at 250° for 5 hours. The product melted at 174° but was identical with Hofmann's 1-mercapto-benzothiazole. The disulfide obtained by the oxidation of this product with potassium dichromate in acetic acid solution after recrystallization from benzene melted at 186°.

In order to verify the assumption that phenyl mustard oil is an intermediate product in the formation of 1-mercapto-benzothiazole from azobenzene, these authors heated the former substance in a sealed tube with sulfur for 5 hours. The yield of mercapto-benzothiazole thus obtained was equal to 45% of the weight of mustard oil used. The constitution of the thiazole was further established by fusion with potassium hydroxide, thus regenerating o-aminothiophenol.

Azobenzene when heated with phenyl mustard oil was found to yield 1-anilidobenzothiazole although the same substance could not be obtained by the direct action of aniline on mercapto-benzothiazole.

Rassow, Dohle and Reim 6 have shown that 1-mercapto-benzothiazole is formed by the action of sulfur on dimethylaniline.

Bedford and Sebrell⁷ as well as Bruni and Romani⁸ have independently described the preparation of 1-mercapto-benzothiazole by the reaction of thiocarbanilide with sulfur when heated under pressure. More recently Romani^{3b} has extended this method of preparation to the three monomethyl derivatives of 1-mercapto-benzothiazole. He recommends the use of an excess of sulfur and zinc oxide as a catalyst. Romani prepared the metallic salts of these methylated mercapto-benzothiazoles but not the disulfides.

Mechanism of the Reaction

Bruni and Romani,⁸ apparently following the lead of Jacobson and Frankenbacher, have sought to explain the formation of 1-mercaptobenzothiazole from thiocarbanilide, monophenyl-thio-urea and methylene-aniline upon the assumption that these substances first decompose to give phenyl mustard oil. They mention an alkali-insoluble residue, which apparently was not further investigated. It is shown in the experimental part of this paper that this insoluble residue consists chiefly of 1-anilidobenzothiazole and that it is formed in largest amounts when thiocarbanilide is used as the starting material. Indeed, it is almost entirely absent when ammonium phenyl-dithiocarbamate or the free aniline and carbon

disulfide are used. The insoluble residue obtained when the zinc salt is used consists almost wholly of zinc sulfide.

If the formation of 1-mercapto-benzothiazole from thiocarbanilide is assumed to take place through its decomposition products, such as aniline and carbon disulfide or phenyl mustard oil, by virtue of their reaction with sulfur, then little or no 1-anilido-benzothiazole should be expected since these latter reactions form only small amounts of the alkali-insoluble residue. These facts seem to indicate that direct sulfurization of the thiocarbanilide offers the most satisfactory explanation for the simultaneous formation of 1-mercapto-benzothiazole and 1-anilido-benzothiazole. The formation of these two products may be readily understood by use of the following mechanism.

1. Thiocarbanilide may be assumed to be in equilibrium with its tautomeric form.

$$C_6H_5NH-C-NHC_6H_5$$
 $= C-NHC_6H_5$ $| SH$

2. This tautomeric form should occur as two geometric isomers, A and B.

3. When A is sulfurized and hydrogen sulfide eliminated 1-anilido-benzothiazole is formed.

4. When B is sulfurized and aniline eliminated 1-mercapto-benzothiazole is formed.

In the experimental part of this paper it is shown that the combined yield of these two products will account for between 90 and 96% of the thiocarbanilide used. These facts are of especial significance since Jacobson and Frankenbacher have shown that 1-anilido-benzothiazole is not formed by the action of aniline on 1-mercapto-benzothiazole.

The formation of 1-mercapto-benzothiazole from phenyl-dithiocarbamic acid and its salts is not so easily traced. It may be explained in one of three ways.

1. The dithiocarbamic acid derivative may decompose with the formation of phenyl mustard oil, which in turn reacts with the sulfur to form the mercapto-benzothiazole. This explanation would correspond to that offered by Jacobson and Frankenbacher⁵ and by Bruni and Romani⁸ to

account for the formation of the mercapto-thiazoles in other cases. The former workers obtained a 45% yield of 1-mercapto-benzothiazole by heating phenyl mustard oil with sulfur. In this Laboratory as high as 60% yields have been obtained by the same method. By reference to Table I it will be seen that phenyl-dithiocarbamic acid and its salts yield 75 to 80% of the same thiazole. It seems doubtful, therefore, whether phenyl mustard oil is an intermediate product in the formation of mercapto-benzothiazoles from phenyl-dithiocarbamic acid and its salts.

- 2. Phenyl-dithiocarbamic acid and its salts not only yield phenyl mustard oil but also undergo a second type of splitting with the formation of aniline and carbon disulfide. This is especially true of the ammonium salt, since thiocarbanilide is found among its decomposition products. Thiocarbanilide should be expected to react with sulfur yielding the mercapto-thiazole according to the scheme given above. Such a reaction would produce a large amount of an alkali-insoluble residue which experiment shows is not the case.
- 3. There is no a priori reason why phenyl-dithiocarbamic acid and its salts should not undergo direct sulfurization as readily as its anilide. The present authors believe this to be a more logical explanation and that the mercapto-benzothiazole is produced by the loss of the appropriate hydrosulfide from the addition product thus formed.

Experimental Part

Preparation of Materials.—The ammonium salts of the aryl dithiocarbamic acids were prepared by the method of Losanitch, by the reaction of the arylamine and carbon disulfide in the presence of ammonium hydroxide or ammonium sulfide in alcoholic solution. The rapid decomposition characteristic of these ammonium salts has caused many investigators to doubt their actual existence.

Ammonium phenyl-dithiocarbamate prepared in the presence of strong ammonium hydroxide is quite stable and after careful drying shows little tendency to decompose. By recrystallization from strong ammonium hydroxide it is obtained as long hexagonal crystals, which when carefully washed and dried have been kept for more than a year without evidence of decomposition. In the presence of moisture however it is slowly converted into thiocarbanilide, carbon disulfide and ammonia, as reported by Losanitch.

These ammonium salts may also be prepared by passing ammonia gas into a solution of aryl amine and carbon disulfide in benzene, but the method has no advantages over the one previously described.

The zinc salts of the aryl dithiocarbamic acids were prepared by adding a solution of zinc acetate in water or ammonium hydroxide to an aqueous solution of the corresponding ammonium salt. They may also be prepared by the method of Krulla¹⁰ who added the metallic oxide to a mixture of the aniline and carbon disulfide. The first method gives the purer product.

Thiocarbanilide and its substituted derivatives were prepared by the action of the aryl amine with carbon disulfide in the usual manner. These products were purified un-

⁹ Losanitch, Ber., 24, 3022 (1891); Ann., 166, 142 (1873).

¹⁰ Krulla, Ber., 46, 2669 (1913).

til the melting points varied not more than 3° or 4° from the highest recorded values in any case.

Apparatus.—The apparatus used in this work consisted of a steel autoclave mounted in an electric resistance oven. The autoclave, which had a capacity of 2 liters, was turned from tool steel and was capable of withstanding a pressure of 2000 pounds. The oven consisted of 3 heating elements specially wound from Chromel wire and mounted on a reinforced frame built up from Alundum cement. The heating unit was effectually insulated by packing in a mixture of asbestos and magnesite. Temperature control, secured by an external hot wire rheostat, was sufficiently exact to make it possible to reproduce any given set of temperature conditions. Temperatures up to 600° were easily obtained.

Procedure.—The substance used to prepare the thiazole was mixed intimately with one molar equivalent of sulfur and placed in the autoclave. Practically all runs were made by bringing the oven to a temperature of 390–400°, then lowering the autoclave to position and allowing the temperature of the reaction mixture to rise until the pressure reached a maximum. The pressure would rise gradually with the temperature to about 170–180° where the increase became much more rapid reaching a maximum at about 225–250°. The pressure generated varied with the substance used to produce the thiazole, being greatest with the ammonium salts and least with the disubstituted thio-ureas. Reproducing the heating conditions did not always give the same yield of product. Usually the autoclave was withdrawn from the oven immediately after the pressure reached the maximum to secure more rapid cooling, and when it was quite cold the accumulation of hydrogen sulfide was blown off and the autoclave opened.

Method of Purification.—The crude reaction product was removed from the autoclave by solution in warm dil. sodium hydroxide solution. This alkaline solution was submitted to steam distillation to remove any free aryl amine. The solution was then filtered from a residue of insoluble material and fractionally precipitated by the addition of small portions of hydrochloric acid. The first precipitates were very dark and carried down most of the coloring matter. The last fractions precipitated consisted of the 1-mercapto-benzothiazole in an almost pure form. The product was redissolved in sodium carbonate solution and reprecipitated further purification varied depending upon the nature of the product and will be described for each individual substance together with its physical and chemical characteristics.

Discussion of the Experimental Results

The data collected in the preparation of 1-mercapto-benzothiazole and 6 of its substituted derivatives are set forth in Table I. Not all of the runs made are listed, but those selected are typical. Failure to prepare all the thiazoles by each of the four methods was due to a lack of sufficient quantity of the aryl amines from which to prepare the necessary starting

materials. In such cases that method was selected which promised to yield the largest amount of easily purified product.

Runs 1 and 5 were made first, and without preheating the oven, thus accounting for the longer reaction time. In later runs the reaction time was shortened to avoid heat decomposition. The ammonium aryl-dithiocarbamates gave in general the best yields, but the products from the zinc salts contained less tarry material and were therefore more readily purified.

The more highly substituted the arylamine, the lower the yield of the thiazole so that only a 34.5% yield of the dimethyl derivative was obtained even from the ammonium salt of xylyl-dithiocarbamic acid.

The disubstituted thio-ureas always yielded large amounts of an alkaliinsoluble by-product. The yield of this substance is markedly lower when the ammonium salt of the aryl-dithiocarbamic acid or the aryl amine and carbon disulfide were used. In the case of the zinc salts the alkaliinsoluble product consisted almost wholly of zinc sulfide.

Nature of the Alkali-Insoluble Material

In the case of thiocarbanilide the alkali-insoluble part of the reaction product was found to consist largely of 1-anilido-benzothiazole. The purification of this anilido derivative proved to be so tedious that the separation of a similar derivative was not successfully completed in any of the other cases.

1-Anilidobenzothiazole.4—The alkali-insoluble residue from the thiocarbanilide-sulfur reaction mixture was dissolved in alcohol and the solution poured into dil. hydrochloric acid. A small amount of acid-insoluble substance was removed by filtration and the anilido derivative precipitated by the addition of sodium hydroxide. Fifty g. of the original residue gave 36 g. of the purified anilido derivative and 5 g. of the acid-insoluble substance, which proved to be mostly 1-mercapto-benzothiazole. After recrystallization from benzene the 1-anilido-benzothiazole was obtained as light yellow crystals melting at 154°. A mixture of this product with 1-anilido-benzothiazole prepared by the action of phenyl mustard oil on azobenzene gave the same melting point.

Analyses. Subs., 0.5470: 46.9 cc. 0.1 N H_2SO_4 . Subs., 0.5102: BaSO₄, 0.5293-Calc. for $C_{13}H_{16}N_2S$: N, 12.38; S, 14.16. Found: N, 12.00; S, 14.25.

Using the above data the calculated yield of pure 1-anilido-benzothiazole available from the 105 g. of alkali-insoluble residue from the thiocarbanilide in Table I is 75.6 g. or 16.5%. By combining this yield with the 73.3% of 1-mercapto-benzothiazole obtained, approximately 90.0% of the thiocarbanilide is accounted for. When one considers the losses incident to purification it is easy to conceive that the actual yield of the two derivatives is much higher, being about 96% on the basis of the crude products.

Disulfides

The disulfides of each of the mercapto-thiazoles described were prepared by the method of Hofmann.⁵ An alcoholic or alkaline solution of the mercapto-thiazole was oxidized by the gradual addition of an alcoholic solution of iodine. The resulting disulfide, insoluble in alcohol or alkalies, precipitated immediately, and after it was filtered, washed and dried was purified by recrystallization from the solvent indicated in each case.

Zinc and Lead Salts

The zinc salts of the mercapto-benzothiazoles may be prepared by either of two methods. A solution of the ammonium salt may be precipitated by the addition of a solution of ammonium zincate, or an alcoholic solution of the thiazole may be precipitated by adding an aqueous solution of any zinc salt. The first method gives the purer product.

Both the normal and the basic lead salts may be prepared, depending upon the method used. The normal lead salts were obtained by precipitating an alcoholic solution of the free thiazole or an aqueous solution of its sodium salt by an aqueous solution of any soluble lead salt. The basic lead salts were obtained by precipitating an alkaline solution of the mer-

capto-benzothiazole by a solution of lead hydroxide in an excess of sodium hydroxide. These salts were thoroughly washed, dried and subjected to analysis without further purification.

The zinc and lead salts of each of the several mercapto-benzothiazoles were prepared, but in only three cases were they actually analyzed and tested for their accelerating power as indicated in the following pages.

1-Mercapto-benzothiazole⁵ is soluble in alcohol, benzene and acetic acid. By recrystallization from dil. alcohol it was obtained as light yellow needles, melting at 177°.

THE ZINC SALT; a white amorphous powder.

Analysis. Calc. for C16H12N2S4Zn: Zn, 15.37. Found: 15.40.

1-Mercapto-3,5-dimethyl-benzothiazole was recrystallized several times from alcohol from which it separates in light yellow crystals melting at 250.5°. It is only very slightly soluble in acetic acid or benzene.

Analyses. Subs., 0.2050, 0.1888: BaSO₄, 0.4904, 0.4523. Calc. for $C_9H_9NS_2$: S. 32.82. Found: 32.85, 32.90.

THE DISULTIDE; fine white needles, m. p. 193°, obtained by repeated precipitation from chloroform with the gradual addition of alcohol.

Analyses. Calc. for C₁₈H₁₆N₂S₄: S, 32.99. Found: 33.02, 33.13.

1-Mercapto-5-ethoxy-benzothiazole was prepared by each of the four methods but only the ammonium p-phenetyl-dithiocarbamate yielded an easily purified product. Recrystallized from 75% alcohol and twice from benzene it was obtained as well-formed, long, cream-colored needles melting at 198° . It is only slightly soluble in benzene and other organic solvents.

Analyses. Subs., 0.1950, 0.1852: BaSO₄, 0.4303, 0.4044. Calc. for C₉H₉NOS₂: S, 30.33. Found: 30.31, 29.99.

Attempts to prepare the disulfide were unsuccessful.

1-Mercapto-5-methoxy-benzothiazole was prepared by each of the four methods but the product in all cases proved very difficult to purify. It was found that by rapidly heating the reaction mixture and rapidly cooling the autoclave a more easily purified product was obtained. Recrystallized from 70% alcohol and twice from benzene it forms light yellow needles melting at 2019.

Analysis. Subs., 0.1505: BaSO₄, 0.3546. Calc. for $C_8H_7NOS_2$: S, 32.48. Found: 32.37.

Attempts to prepare substituted mercapto-benzothiazoles from o-anisidine, the o- and p-chloro- and bromo-anilines and p-aminophenol were unsuccessful. Benzidine and carbon disulfide yielded an alkali-soluble product melting above 250°, which was not further investigated.

Acknowledgment

The authors wish to acknowledge the coöperation of the Goodyear Tire and Rubber Company as expressed through Dr. E. B. Spear, former Research Director, for the loan of apparatus and the testing of samples. Further acknowledgment is due Mr. C. W. Bedford for helpful advice during the early part of the work, to Dr. W. J. Kelly for valued suggestions and to Mr. C. M. Carson for assistance rendered.

Summary and Conclusions

- 1. The chemistry of the zinc and ammonium salts of phenyl-dithiocarbamic acid has been extended and the work of Losanitch verified.
- 2. Three new methods for the preparation of 1-mercapto-benzothiazole and its substituted derivatives have been described.
- 3. A fourth method previously described by one of us and independently announced about the same time by Bruni of Italy, has been extended to these derivatives.

- 4. The mechanism of the reaction involved in the formation of 1-mercapto-benzothiazoles by the action of sulfur on disubstituted thioureas is fully discussed. Experimental evidence is offered in support of the view that this reaction takes place by virtue of direct sulfurization of the *cis*-mercapto form of thiocarbanilide and subsequent loss of the aryl amine to form the mercapto-benzothiazole. It is also pointed out that sulfurization of the *trans*-mercapto form of thiocarbanilide and loss of hydrogen sulfide explains the simultaneous formation of anilido-benzothiazole.
- 5. Direct sulfurization and subsequent elimination of the corresponding hydrosulfide is offered as the best explanation of the formation of mercapto-benzothiazoles by the action of sulfur on the aryl dithiocarbamic acids and their salts.
- 6. Six substituted mercapto-benzothiazoles are described together with four of the corresponding disulfides.
- 7. Methods are given for the preparation of the zinc, normal lead and basic lead salts of the 1-mercapto-benzothiazoles and in three cases such salts are described.

Columbus, Onio

[Contribution from the Chemical Laboratory of the Johns Hopkins University] THE INFLUENCE OF SULFUR ON THE COLOR OF AZO DYES

By W. R. Waldron¹ and E. Emmet Reid Received June 11, 1923

The purpose of the present investigation was to study the effect of the sulfur atom and of the sulfone group, in various positions, on the color of azo dyes.

Brand² and coworkers found the —SCH₃ group to be strongly bathochromic as compared with —OCH₃ when introduced into azobenzene or into triphenyl carbinol, but they did not prepare any real dyes except to tetrazotize the dimethylether of o,o'-dimercapto-benzidine and couple it with salicylic acid, which gave a direct yellow on cotton, and with Hacid which gave a blue shade.

Several workers³ have mentioned that various amines containing sulfur give red dyes when diazotized and coupled with β -naphthol. The importance of thio-indigo and other dyes containing sulfur appeared to warrant a thorough investigation of the influence of sulfur in azo dyes.

Two classes of dyes have been considered. (1) Those derived from mono-amines, particularly those from p-thio-anisidine, CH₃SC₆H₄NH₂, and its sulfone, CH₃SO₂C₆H₄NH₂, which have been contrasted with the corresponding dyes from p-toluidine and p-anisidine, thus showing the

¹ From a dissertation by W. R. Waldron, 1922.

² Brand, (a) Ber., 42, 3463 (1909). Brand and Wirsing, (b) Ber., 45, 1757 (1912); (c) 46, 820 (1913). Brand and Stallmann, (d) Ber., 54, 1578 (1921).

relative effects of the groups CH3-, CH3O-, CH3S- and CH3SO2as auxochromes. The bases containing sulfur and the sulfone group have been prepared, diazotized and coupled with a number of standard intermediates, such as R-salt and chromotropic acid, and the resulting dves compared with the corresponding known dves containing methyl and methoxyl groups. In addition to the bases containing the CH₃S - group, a number have been made containing other radicals in place of methyl joined to sulfur, but the influence of the sulfur atom overshadows that of the radical. Methoxyl is a much stronger auxochrome than methyl; the CH₃S- group has been found to be stronger still, while oxidation of this group to the sulfone CH₃SO₂ - destroys this effect entirely, the group actually appearing as hypsochromic. (2) Those derived from diamines, which may be regarded as benzidine with various groups interposed between the two rings. A number of bases containing such groups as -S-, -SO₂-, -CH₂S-, -SCH₂S-, etc., between the two rings were made and dves prepared by diazotizing and coupling with standard intermediates. The bases most extensively compared were benzidine, thio-aniline, thio-aniline sulfone and one derived from mustard gas, NH2C6H4SCH2-CH2SCH2CH2SC6H4NH2. It was hoped that the dyes from these new bases would resemble those from benzidine, but it appears that the peculiar properties of benzidine dyes are lost when the two rings are separated. On the contrary, a base such as NH₂C₆H₄SCH₂CH₂SC₆H₄NH₂ resembles 2NH₂C₆H₄SCH₃. The -S- and -SO₂- groups have the same effects in the diamino as in the mono.

In all the dyes made, the sulfur atom has a decided bathochromic effect, provided it is joined directly to the ring carrying the azo chromophore group, but it has little effect when it is separated from the ring by even a methylene group. In the dyes derived from the two isomeric bases, $\mathrm{NH_2C_6H_4SCH_2C_6H_5}$ and $\mathrm{NH_2C_6H_4CH_2SC_6H_5}$, the sulfur has a decided effect in the first case and practically none in the second.

As intermediates, a large number of new compounds have been prepared, along with some that have been previously described. The general method has been to obtain the nitro compound by condensing a halide with the sodium salt of p-nitro-thiophenol, or p-nitrobenzyl bromide with the sodium compound of a mercaptan. One portion of the product has been reduced to the amino-sulfide and the other portion oxidized to the sulfone and then reduced to the amino-sulfone. The details of the numerous preparations are given in tables. The diazotizing, coupling and dyeing were according to accepted methods.

Materials

The p-nitrobenzyl bromide used in this work was prepared following the method of Brewster⁴ with slight modifications. p-Nitro-toluene was brominated in the sunlight

⁴ Brewster, This Journal, 40, 406 (1918).

in Pyrex glass at the boiling point of carbon tetrachloride which was used as solvent, a trace of iodine being used as a bromine carrier. When the amount of solvent recommended by Brewster is reduced to half, the most of the p-nitrobenzyl bromide crystallizes on cooling to 5° , leaving the oily by-products in solution. By one recrystallization from three parts of alcohol the compound was obtained in long needles, m. p., 99° . By removing the carbon tetrachloride first, the product was contaminated with oils which necessitated two or three recrystallizations before it was obtained pure; yield, 55-65%.

p-Nitro-thiophenol was first prepared by Willgerodt.⁵ The preparation has been studied and improved by Mayer,⁶ Kehrmann and Bauer,⁷ Brand⁸ and Blanksma.⁹

In the following work the sodium salt of the mercaptan was prepared following in part the methods of Wohlfahrt, ¹⁰ Mayer, ¹¹ and Brand. ¹² Brand states that this salt is not stable above 100° and that its solution oxidizes rapidly in the air. We isolated the salt readily in a very pure state, dried it at 60°, and found that it keeps indefinitely without apparent change.

One gram-mole of p-nitrochlorobenzene is suspended in 150 cc. of alcohol, to which is added slowly with mechanical stirring 1 mole of sodium disulfide (100% excess) in 600 cc. of water. The reaction is exothermic and the mixture boils by the time all of the disulfide has been added. After the charge has been stirred for 5 minutes it is poured into 2 liters of cold water. By this time practically all of the p-nitrochlorobenzene has reacted; the solution contains a mixture of the sodium salt of the mercaptan and the disulfide. After dilution, the disulfide is filtered off and the red solution acidified, precipitating the impure free mercaptan. This is filtered off at once and dissolved in 500 cc. of boiling 5% sodium hydroxide solution. The hot alkaline solution is filtered to remove any disulfide or impurities carried by the mercaptan. It is allowed to cool and saturated sodium hydroxide solution is added causing an almost complete precipitation of the sodium salt in large red plates. The disulfide residue obtained is reduced with sodium hydroxide and sodium sulfide, following the procedure of Brand, and the solution containing the sodium salt is treated in the same way as described above. The yields obtained average 60%, being equally divided between the two steps in the process.

The p-nitrotoluene, p-nitrochlorobenzene and a large number of naphthalene intermediates used in this work were obtained through the courtesy of E. I. du Pont de Nemours and Company. We are also indebted to them for much information as to carrying out various processes.

I. (a) Alkyl and Aryl para-Nitro-thiophenyl Ethers, RSC₆H₄NO₂

The methyl, ¹⁸ ethyl ¹⁴ and benzyl ¹⁵ compounds had previously been made, the first two by the same method as used here.

The alkyl derivatives (including benzyl) were made by dissolving 0.1 mole of the halide in 75 cc. of 95% alcohol and adding 0.105 mole of sodium

p-nitro-thiophenate made into a thick paste with water. The mixture is stirred vigorously for 5 minutes and then heated to boiling on a waterbath. The reaction is soon complete, the solution remaining reddish on account of the slight excess of sodium mercaptide. The less soluble solid products separate as the solution is cooled to 0° . The oils were obtained by distilling most of the alcohol, washing the residue with water and dil. alkali and finally drying with calcium chloride. The solids are best recrystallized from 50--80% acetic acid.

The details of the preparations together with the properties of the products are given in Table I. Methyl iodide, benzyl and phenacyl chlorides were used and the bromides of all of the other alkyls.

Fromm and Wittmann¹⁷ obtained p-nitrophenyl-thioglycolic acid by condensing the mercaptide with sodium chloro-acetate. This and the corresponding amine have also been prepared by Friedlaender and Chwala.¹⁸ They made the acid from p-nitro-chlorobenzene and thioglycolic acid with sodium hydroxide. We obtained it from p-nitro-thiophenol and chloroacetic acid in the presence of alkali.

The same reaction took place with glycol-chlorohydrin and sodium

¹⁶ Parr, J. Ind. Eng. Chem., 11, 230 (1919).

¹⁷ Ref. 15a, p. 2273.

¹⁸ Friedlaender and Chwala, Monatsh., 28, 274 (1907).

p-nitro-thiophenolate, forming the thio-ether of monothioglycol as yellow plates; m. p., 59°. On refluxing this compound with hydrobromic acid for several hours the bromide NO₂C₆H₄SCH₂CH₂Br was obtained in 86% yield as yellow plates; m. p., 58°.

The phenyl derivative was readily prepared in 95% yield from p-nitro-chlorobenzene and the sodium salt of thiophenol in alcoholic solution. It had previously been made by Kehrmann and Bauer¹⁹ by eliminating the amino group from p-nitro-p'-amino-diphenyl sulfide.

Esters of p-Nitro-thiophenol

Esters were readily obtained by using benzoyl chloride, phosgene and thiophosgene. These were recrystallized from about 50% acetic acid as they are too soluble in strong acetic acid. Sulfones could not be obtained by oxidizing these esters. On reduction, only the *p*-nitrophenylthiol-benzoate (6 g.) gave the desired amine (4 g.; 75%); m. p., 115°. The calculated percentage of sulfur was 14.01; that found, 14.10.

The chlorides of p-toluene-sulfonic and m-nitrobenzene sulfonic acids were used in the same way but the desired esters could not be obtained.

(b) Alkyl and Aryl para-Amino-thiophenyl Ethers, RSC₆H₄NH₂

The methyl²⁰ compound had been prepared by the reaction of p-aceto-amino-thiophenol on methyl sulfate with the subsequent removal of the acetyl group, and the ethyl,²¹ phenyl²² and benzyl¹⁵ compounds by the reduction of the corresponding nitro compounds with tin and hydrochloric or acetic acid. We considered that reductions with iron and a trace of acetic acid, though much slower, would obviate the danger of splitting the molecule at the sulfur atom. The method with iron was found to be quite satisfactory.

To 5 g. of the nitro compound is added 15 g. of iron dust, 0.1 cc. of concd. acetic acid and 100 cc. of water, and the charge is stirred for 10 hours at $85-90^\circ$. At the end of this time the mixture is made alkaline with sodium carbonate and filtered. The filtrate is shaken with benzene to obtain the oil and the iron residue extracted four times with hot benzene. The combined extract is distilled on a water-bath, the last traces of benzene being removed by applying a vacuum. The oil is then added to 100 cc. of 5% sulfuric acid and the difficultly soluble sulfate so obtained is recrystallized from boiling

water, a small amount of diatomaceous earth being added to remove any tar. The yields in all cases are 85-90%.

All of these bases except the phenyl are oils with practically no odors; they darken rapidly in the light and the solubility of the sulfates decreases rapidly with increase in molecular weight, the sulfate of the benzyl compound being almost insoluble in boiling water. The hydrochlorides are much more soluble and may be obtained by saturating the benzene solution of the base with dry hydrogen chloride.

Details of the preparations and the properties of the compounds are given in Table II. The sulfates of the bases were analyzed by dissolving in hot water and adding barium chloride solution, the figures given being the sulfur in the sulfate ion.

^a Prepared by other authors; the phenyl is given as melting at 93° and 95°.

(c) Alkyl and Aryl para-Nitrophenyl Sulfones, RSO₂C₆H₄NO₂

Three sulfones of this series have been prepared previously; the methyl^{15b} and benzyl²³ by the oxidation of the corresponding sulfides with chromic acid and the phenyl²⁴ by the reaction of p-nitro-chlorobenzene on benzene sulfinic acid under pressure. The chromic acid method was used in this work.

Ten g. of the sulfide is dissolved in 100 cc. of 80% acetic acid and the mixture heated to boiling, then a saturated solution of chromic acid in water is added a little at a time until an orange coloration denotes the presence of an excess. After boiling for 15 minutes, an equal volume of water is added and the solution allowed to cool. The sulfone separates and is recrystallized from 50% acetic acid to remove chromium compounds. The sulfones are obtained as white plates or needles which are recrystallized to constant melting point.

The sulfones are white solids, crystallizing very well from acetic acid or alcohol. They are very stable towards oxidizing agents, as none of them

²³ Ref. 15a, p. 2270. Ref. 15b.

²⁴ Ullmann and Posdermadjian, Ber., 34, 1154 (1901).

shows any tendency to break at the sulfur atom forming sulfonic acids. The oxidation with chromic acid is exothermic; at the same time the product is purified by oxidation of any disulfides present to soluble sulfonic acids. The sulfones with low melting points separate from the oxidizing mixture as oils but solidify after standing for several hours. The yields are about 85%.

Details of the preparations are given in Table III together with properties of the products. The analyses were made by the method of Parr.

(d) Alkyl and Aryl para-Aminophenyl Sulfones, RSO₂C₆H₄NH₂

Two of this series of amino sulfones have been prepared previously, the methyl^{15b} and phenyl²⁵ derivatives by the reduction of the nitro bodies with tin and hydrochloric acid.

We have prepared others by reduction from the corresponding nitro compounds described above.

Five g. of the nitrophenyl sulfides. When the reduction is finished the charge is diluted with two volumes of water, heated to boiling and filtered hot. In the case of the first 7 products, the iron residue is extracted twice more with 500 cc. of hot water, but with the last two alcohol is used, since they are not very soluble in water. The water or alcohol extracts are cooled to 0° , at which a large percentage of the product crystallizes; but in the case of the methyl and ethyl derivatives it is necessary to evaporate to a small volume before any solid is obtained. The yields are about 90%, being low in the case of the methyl and ethyl compounds on account of their greater solubility.

The amino sulfones are white, odorless solids, and are much more soluble than the corresponding amino sulfides, the solubility decreasing with increase in the size of the radical. The first 4 numbers of the series melt lower than the corresponding nitro compounds while the last 5 melt higher. The methyl and ethyl compounds darken considerably on standing in light and air but the others remain white.

²⁵ Ref. 24, p. 1155.

Details of the preparations are given in Table IV.

II. (a) Alkyl and Aryl para-Nitrobenzyl Sulfides, NO₂C₆H₄CH₂SR

No para derivatives of this class have been made though $ortho^{26}$ and $meta^{27}$ nitrobenzyl-methyl sulfides have been prepared and also the corresponding amines. In these cases the sodium salt of the nitrobenzyl mercaptan was used with methyl iodide. As the para mercaptan is rather difficult to prepare, it was thought that the para sulfide could be obtained by the reaction of p-nitrobenzyl bromide on the sodium salt of the various mercaptans.

The methyl and ethyl derivatives could not be prepared in this way as, on adding a solution of the theoretical quantity of sodium ethylate saturated with an excess of the mercaptans to p-nitrobenzyl bromide, p,p'-dinitro-dibenzyl sulfide, ²⁹ m. p., 159°, resulted, though the butyl, *iso* amyl and phenyl derivatives were thus obtained, using the mercaptans.

One-tenth g.-mole of p-nitrobenzyl bromide is dissolved in 100 cc. of alcohol and heated to 60°. To this is added 0.1 mole of sodium mercaptide made by adding an alcohol solution of 0.1 mole of sodium ethylate to the mercaptan. This is added slowly with rapid agitation at 60° and after 15 minutes the alcohol is distilled and the excess of mercaptan distilled with steam. The oil is washed with water and dried with calcium chloride. In the case of the phenyl compound which is solid it is recrystallized from alcohol. Details are given in Table V.

The mercaptan salt has no apparent reducing action on the nitro group when p-nitrobenzyl bromide is still present in excess, but beyond this point it reduces the sulfide to a red substance which is probably an azo compound. Excess of the free mercaptan has no effect, the sodium salt being

necessary for the reduction. The reaction seems best at $60-70^{\circ}$, for at room temperature the *p*-nitrobenzyl bromide is rather insoluble in alcohol. The phenyl compound is solid and may be purified by crystallization from alcohol or acetic acid. The butyl and *iso* amyl derivatives are

TABLE V

Preparation and Properties of para-Nitrobenzyl Alkyl or Aryl Sulfides, $NO_2C_6H_4CH_2SR$

higher-boiling oils which decompose on distillation at 5 mm. pressures. They have an odor similar to the corresponding oils in the previous series. The yields are about 75%.

(b) Alkyl and Aryl p-Aminobenzyl Sulfides, NH2C6H4CH2SR

These compounds are prepared in the same way as the amino sulfides of the previous series, and resemble them in properties, the phenyl compound being solid also, but having a lower melting point. The oils were isolated as the slightly soluble sulfates which were recrystallized to remove *p*-aminobenzoic acid.

TABLE VI

Preparation and Properties of para-Aminobenzyl Alkyl or Aryl Sulfides, $\mathrm{NH_2C_6H_4CH_2SR}$

Alkyl	Nitro					Sul	fur ^a
or aryl	sulfide G.	G.Yi	eld— %	М. р. ° С.	d ₂₅	Cale.	Found %
Butyl	13	10	89		1.0321	6.66	6.75
isoAmyl	10	8	41		1.0307	6.20	6.28
Phenyl	7.25	6	94	72		14.91	35.13

^a The first two of the series are oils, and the analyses were therefore made on the sulfates of the bases, only the sulfur in the sulfate ion being determined. These sulfates are obtained as curdy precipitates, very slightly soluble in cold water, something like 1 g. per liter. On recrystallization from hot water, they separate in flocculent form.

(c) Alkyl and Aryl para-Nitrobenzyl Sulfones

The sulfones of this class are prepared in the same way as those of the previous series. They are crystalline solids, and are formed with a good yield,—about 75%. The butyl and isoamyl compounds are contaminated with 5–10% of p-nitrobenzoic acid, which lowers their melting points and which it is practically impossible to eliminate by crystallization. It is removed by agitating several times with a large volume of 5% solution of sodium carbonate. The sulfones may be recrystallized from acetic acid or alcohol. They are very slightly soluble in water; when the oxidation is carried out with a water suspension of the sulfide a poor yield of sulfone

Phenyl.....

contaminated with tar is obtained. Hot 20% sodium hydroxide solution decomposes the sulfones, giving a red solution and a yellow precipitate (m. p., 195°) which contains no sulfur and is probably a compound of the formula $\mathrm{NO_2C_6H_4CH:CHC_6H_4NO_2}$ (m. p., $210\text{--}216^\circ$).

A similar decomposition³⁰ has been noted with sulfone esters.

(d) Alkyl and Aryl para-Aminobenzyl Sulfones, NH2C6H4CH2SO2R

The amino sulfones are prepared in the same way as those of the former series, starting with material free from p-nitrobenzoic acid, and have similar properties. They are removed from the iron residue by extraction with alcohol. They were recrystallized by dissolving in hot alcohol, adding water cautiously to incipient separation and cooling.

III. (a) p,p'-Dinitro-diphenyl Derivatives with Various Groups between the Two Rings, NO₂C₆H₄.X.C₆H₄NH₂

In this series of compounds, p,p'-dinitro-diphenyl may be considered the simplest member, the more complicated ones consisting of various radicals containing sulfur between the two rings, X in the above formula standing for the following groups: $-S-, -CH_2S-, -CH_2SCH_2-, -SC_2H_4S-, -SC_2H_4S-, -SC_2H_4SC_2+, -SC_2H_4SC_2-, -SC_2H_4S-$

Nietzki and Bothof³² prepared dinitro-diphenyl sulfide by treating p-nitro-chlorobenzene with sodium sulfide. This reaction was rather slow and did not go to completion. p,p'-Dinitro-benzylphenyl sulfide was formed from p-nitrobenzyl bromide and sodium p-nitro-thiophenol. p,p'-Dinitro-dibenzyl sulfide was prepared by Fischer²⁹ from p-nitrobenzyl chloride and ammonium sulfide. Others of the series containing two or more separated sulfur atoms we obtained from two molecules of sodium p-nitro-thiophenolate with the following halides, methylene iodide, ethyl-

³⁰ Michael and Comey, Am. Chem. J., 5, 349 (1883-84).

ene bromide, trimethylene bromide, benzal chloride, mustard gas and mustard gas sulfone. In all cases the reaction took place at once with the separation of the new compound. Methylene chloride did not react at all because of its low boiling point and the inactivity of the chlorine atoms; hence, the iodide was used. In the case of ethylene bromide the reaction took place on warming to 70°, but when one ethylene hydrogen has been replaced by methyl, as in propylene dibromide, the reaction is much slower and the resulting compound was contaminated with a large amount of disulfide, produced by oxidation of the mercaptan either by the nitro group or by air. This takes place only to a very limited extent when the reaction is rapid. This was borne out by the fact that using butylene dibromide, in which two ethylene hydrogen atoms have been replaced by methyl, the desired reaction was so slow that the product obtained consisted almost entirely of disulfide.

Mustard gas and its sulfone both react immediately with the mercaptide, their chlorine atoms being much more active.

These nitro sulfides are yellowish, odorless solids which crystallize well from acetic acid, and are insoluble in water and only slightly soluble in alcohol. The yields average about 85%.

Inasmuch as the different compounds are made, using several intermediates, and the preparation is self-explanatory from Table IX, following, it will suffice to describe one completely, the others being made in the same way.

One-tenth g.-mole of methylene iodide is dissolved in 100 cc. of alcohol and 0.21 mole of sodium p-nitro-thiophenolate, with enough water to produce a thick paste, is added. The mixture is stirred while being heated on a water-bath to 65–70°. After a few minutes at this temperature, the reaction is complete and the solid sulfide partly precipitates. On cooling to 0°, practically all of the sulfide separates and is filtered off. It is purified by boiling with a 1% sodium carbonate solution and recrystallized from 80% acetic acid in which it is fairly soluble hot, and very slightly so cold; the latter treatment removes any dinitro-diphenyl disulfide formed.

(b) p,p'-Diamino-diphenyl Compounds (NH2C6H5)2X

Two amines of this group have been made previously. Nietzki and Bothof^{3a} prepared thio-aniline by reducing the dinitro derivative, while Mertz and Weyth³¹ prepared it by a fusion of aniline with sulfur. O. Fischer³² reduced dinitro-dibenzyl sulfide to the corresponding diamine with tin and hydrochloric acid. We have prepared these and the other amines of this group by reducing the dinitro compounds just described with iron and acetic acid as outlined above. Benzene was used for extracting the amines from the iron residue. On concentrating and cooling the benzene solutions, the amines were usually obtained as crystals. One of them is an oil.

The amines are very slightly soluble in water, more soluble in alcohol and very soluble in benzene. The solubility in all cases decreases rapidly with increase in molecular weight.

(c) Sulfones from the Dinitro-diphenyl Compounds

Fromm and Wittmann³⁸ prepared dinitro-diphenyl sulfone by oxidizing the sulfide dissolved in acetic acid with chromic acid. Following the procedure described above for preparing mononitro sulfones, we obtained disulfones in all cases except from p,p'-dinitro-diphenyl-dithiomethane, where the two sulfur atoms are separated only by a CH₂ group and oxidation breaks the molecule, yielding only soluble sulfonic acids. Various oxidizing agents were tried with the same result. In the case where the two sulfur atoms were separated by two CH₂ groups, no difficulty was encountered even when three sulfur atoms are present.

The sulfones are insoluble in water, slightly soluble in alcohol, and

fairly soluble in boiling 80% acetic acid, the last member, however, being insoluble in this, as the solubility of the series decreases markedly with the increase in molecular weight. They are white solids with high melting points, and are obtained in yields averaging 75%.

(d) Reduction Products of p, p'-Dinitro-diphenyl Sulfones

The preparation of diamino sulfones is much more difficult than that of the mono-amine sulfones in Classes I and II. Fromm and Wittmann³⁴ obtained diamino-diphenyl sulfone by reducing the corresponding nitrosulfone with tin and acid. This reduction also took place with iron and acetic acid but on carrying it to the next member of the series, p,p'-dinitrobenzylphenyl-sulfone, a compound was obtained which seemed by analysis to be a nitro-amino sulfone and could not be reduced further by this means; m. p., 215° (decomp.). Analysis: Calc. for S, 10.98. Found: 11.26. Dinitro-dibenzyl sulfone yielded a white, tarry substance.

These last two reductions were readily effected by using tin and hydrochloric acid in alcohol, the tin double salt separating on cooling. From this the desired base was obtained.

In the case of the di- and tri-sulfones, neither method of reduction was satisfactory. According to the analyses of the compounds isolated, both nitro groups had been reduced, and also one sulfone group to a sulfide; or both sulfone groups to sulfoxide, this being the case with the di- and tri-sulfones. Various methods of reduction were tried but the desired compounds were not obtained; according to the analyses, NO₂C₆H₄SO₂-

Preparation and Application of the Dyes

1. From Mono-amines. See Tables II, IV, VI and VIII

One-hundredth g.-mole of the base (in case it is liquid the equivalent quantity of the sulfate) is dissolved in two equivalents of hydrochloric acid in 75 cc. of water, and diazotized with one equivalent of sodium nitrite at 5° , maintaining an excess of nitrate for a half-hour, as shown by the starch-potassium iodide test. One-hundredth mole of R-salt, plus 5° excess, is dissolved in 50 cc. of water to which have been added two equivalents of sodium carbonate, and the mixture is cooled to 5° . The diazo solution is added to the alkaline solution of R-salt at this temperature, and the whole stirred half an hour. In some cases the dye separates immediately, while in others it remains in solution. At the end of this time a small sample is salted out and spotted on paper, the clear ring being tested with R-salt solution to detect the presence of any diazo body; none should be present, as shown by the absence of color on this ring. The solution should also be alkaline to Brilliant Yellow paper, adjustments being made in cases where it does not answer these requirements. After the coupling is complete the solution is heated to 45° and enough salt is added in small amounts to obtain a clear, or slightly colored, ring when spotted on paper. The dye is filtered out from the warm solution and dried at 80° .

These dyes belong to the class of acid colors, dyeing animal fiber from a weak acid bath, the application being made in the following way. As the strength of the several dyes varies considerably due to the amount of salt present, in order to obtain dyeings of approximately the same strength for comparison, it is necessary to make standard solutions of 500 cc. of 0.1%, of each. These are spotted on paper and the weak and strong ones noted, corrections being made in the volume of solution used for dyeing. For a 2% dyeing on a 10 g. woolen skein, 200 cc. of this solution is used, and more or less is added according to the strength. The measured volume is diluted to 700 cc., 4% sulfuric acid and 15% Glauber's salt, based on the weight of material dyed, being added. The wool which has been thoroughly wet in warm water, is immersed and the whole is heated slowly to boiling, while the skeins are turned frequently to insure even dyeing. After 30 minutes' boiling the bath is exhausted, and the skeins are removed, washed and dried.

Both in the preparation of the dyes and the application, approximately standard solutions of the various acids, bases and salts were used, so that the desired quantities could be easily measured.

In this same manner, dyes were made from thio-anisidine and thio-ansidine sulfone, the following intermediates being used in addition to R-salt: salicylic acid, Schaeffer's salt, Neville and Winther's acid, L-acid, (1-OH, 5-SO₃H) and chromotrope acid. For comparison, the corresponding dyes were prepared from p-toluidine and p-anisidine.

2. From Diamines. See Tables X and XII

One-hundredth g.-mole of the base is dissolved in 100 cc. of hot water containing 0.04 g.-mole of hydrochloric acid, cooled to 5° and diazotized with 0.02 g.-mole of sodium

nitrite, while an excess of nitrite is maintained for one-half hour as shown by the starch-iodide test; 0.022 mole of salicylic acid is dissolved in an equivalent quantity of sodium hydroxide, so that it is just alkaline to Brilliant Yellow paper, and then 0.2 mole of sodium carbonate is added. This solution is cooled to 5° and the tetrazotized base, which has previously been neutralized to a slight acidity to congo red paper, is added slowly at this temperature. After three hours it is tested for excess diazo with R-salt solution, by spotting a sample on paper and testing the clear ring. This should be negative, showing that the first molecule of salicylic acid has coupled; 0.02 moles of sodium hydroxide is added and the temperature brought slowly to 35° , stirring overnight at this temperature. In the morning the second molecule should be coupled, and the solution should be strongly alkaline to Brilliant Yellow paper. To test for excess of the second diazo group, a small amount of color is diluted and divided between two test-tubes, and to one several drops of 1% H-acid solution are added. Both are heated to boiling and should remain the same color. A change in the one containing H-acid denotes the presence of free diazo group. The dyes are heated to 50° and salted out.

Dyes containing salicylic acid are commonly known as acid chrome colors, since the color is fixed on the wool with a dichromate mordant. These colors were dyed as follows.

A standard solution of dye is made as described above, and the quantity measured to give a 2% dyeing; 3% acetic acid and 15% Glauber's salt are added, the skein is immersed and boiled for 1/2 hour. An addition of 3% acetic acid is made and the boiling continued for another half hour. In case the dye is to be chromed, this is followed by adding 10% dichromate and boiling for another half hour, after which the skeins are removed, washed and dried.

Thio-aniline, thio-aniline sulfone and the diamine from mustard gas, NH₂-C₆H₄SCH₂CH₂SCH₂CH₂SC₆H₄NH₂, were tetrazotized and coupled with the other intermediates which were used with the mono-amines described above.

At the same time similar dyes from benzidine itself were prepared for comparison. The couplings were made in the same way as with salicylic acid described above, except that sodium carbonate was substituted for the hydroxide, the couplings being made in a weaker alkaline solution. In this series also the first molecule of intermediate was coupled at a low temperature and, after testing with R-salt for uncombined tetrazo body, the temperature was elevated to 35° and the suspension stirred overnight.

The dyes obtained were applied to wool in exactly the same way as the acid dyes obtained from mono-amine bases.

Additional dyes were made with these same bases by coupling them with intermediates used to produce direct dyes, using naphthionic, gamma-and H-acids. The bases were tetrazotized in the usual way, but the couplings were made in the case of the first two intermediates in neutral solutions, neutrality being maintained during the formation of hydrochloric acid in the course of the coupling; with H-acid the solution was kept alkaline throughout by an excess of carbonate.

These colors are applied to cotton in the following way.

A standard 0.1% solution of the dye is prepared as usual and the required volume for the desired strength is diluted to 250 cc., 15% of sodium chloride, based on the weight of skein used, being added. The skeins are introduced into the boiling solution and allowed to remain there for $^3/_4$ hour and frequently turned.

Colors of the Dyes³⁵

Mono-amine Bases with R-salt. Dyes from Bases of Tables II, IV, VI and VIII

The first study was of the bases in Table II to determine the effect of changing the radical in NH2C6H4SR, R being methyl, ethyl, propyl, isopropyl, butyl, isobutyl, iso-amyl phenyl and benzyl. All of these give red dyes with R-salt, there being no distinguishable difference in color among them except that the -SCH3 is a bordeaux and the -SC6H3 is scarlet. The benzyl group acts exactly like the alkyls higher than the methyl group. The sulfur atom appears here as strongly bathochromic and its influence is so decided that the size or nature of the group beyond it makes little difference; or, what is more probable, the part of the auxochrome group which is in immediate union with the benzene nucleus is the decisive factor. This is shown by a comparison of the isomeric bases containing the groups —SCH₂C₆H₅ and —CH₂SC₆H₅. The dye from the first is deep red, while that from the second is tangerine, the auxochrome effect of the sulfur being lost by the interposition of the -CH₂- group. The same color is shown by the dye from the base containing -CH2SC3H11 (iso). The oxidation of the -S- in these two to $-SO_2$ — has no effect on the color.

Contrasting the amino sulfones of Tables IV and VIII with the amino sulfides of Tables II and VI we find that the oxidation of —S— to —SO₂—destroys the effect of the —S— completely; in fact the sulfone group is actually hypsochromic, the dyes from NH₂C₆H₄SO₂R being gold while the one from aniline itself is orange. The size and character of the radical carried by the sulfone group have no effect on the color, the dyes from all the bases in Table IV being indistinguishable.

A curious fact appears with the dye from $NH_2C_6H_4SCOC_6H_5$. This contains —S— joined to the nucleus and, according to what was said above, was expected to be deep red like the dye from $NH_2C_6H_4SCH_2C_6H_5$ from which it differs only in the oxidation of the — CH_2 —. The dye in question is scarlet but its tinctorial power is so diminished that only a moderate color was obtained by double strength dyeing. Here oxidation, even of a group beyond the sulfur, has lightened the color.

2. Mono-amine Bases with Various Intermediates

As it appears that the alkyl present in the sulfide and sulfones is of little consequence, further comparisons were made between dyes containing the groups $-CH_3$, $-CCH_3$, $-SCH_3$ and $-SO_2CH_3$; that is, p-toluidine, p-anisidine, p-thio-anisidine and its sulfone were diazotized and coupled with salicylic acid, Schaeffer's salt, Neville and Winther's acid, L-acid,

³⁵ Thanks to Dr. R. E. Rose, the color designations here given are from the Technical Laboratory of E. I. du Pont de Nemours and Co.

R-salt and chromotrope acid. The colors of the dyes obtained are given in the table below.

Table XIII
Colors of Dyes from Bases with Various Intermediates

Acids	-СН₃	Auxochromes —OCH ₃	—SCH₃	-SO2CH2
Salicylic	Yellow	Yellow	Yellow, darker	Gold
Salicylic, chromed	Yellow	Yellow	Old gold	Old gold
Schaeffer's	Orange	Scarlet	Red	Gold
Neville and Winther's	Scarlet	Scarlet	Red	Orange
L-acid	Red	Red	Bordeaux	Old gold
R-salt	Scarlet	Red	Bordeaux	Gold
Chromotrope	Cardinal	Heliotrope	Violet	Red

We have here the same color relations, the auxochromes being arranged in the order: $-SCH_3 > -OCH_3 > -CH_3 > -SO_2CH_3$. This is true regardless of the nature of the second constituent of the dye.

3. Diamine Bases with Salicylic Acid, Chromed. See Tables X and XII

The colors obtained are as follows: (1) benzidine, gold; (2) thioaniline, old gold; (3) and (4) the rings joined by -CH2S- and -CH2-SCH₂—, old gold; (5) by —SCH₂S—, old gold but deeper; (6) and (7) by -SCH₂CH₂S- and -SCH₂CH₂SCH₂CH₂S-, gold. The presence of sulfur connected to two rings in thio-aniline darkens the color considerably as compared with benzidine. The introduction of one or two methylene groups with one sulfur atom weakens the coloring property, and the sulfone is still weaker. In the case where two sulfur atoms are separated by CH₂, the color is practically the same as with thio-aniline, the influence of the CH2 being overcome by the relatively large amount of sulfur adjacent. Where the sulfur atoms are farther apart, being separated by ethylene, the color is much lighter and more greenish, lacking the reddish overcast obtained with thio-aniline and its sulfone. Where the two rings are separated by three sulfur atoms and two ethylene groups, the color is still darker and greener, while the introduction of a sulfone group in the center between the two ethylenes does not change the color at all, showing again that the sulfur atoms connected directly to the rings are the ones that exert the most influence on the color.

The sulfone of thio-aniline gives an old gold, the same as thio-aniline but darker apparently reversing the relationship found above between sulfides and sulfones. The dye from mustard gas sulfone is practically the same as that from mustard gas, which is as would be anticipated since the —SO₂— in the group —SCH₂CH₂SO₂CH₂CH₂S— cannot be expected to show much effect.

For these diamines, alicylic acid was used because of the importance of Anthracene Yellow C (Cassella)³⁶ obtained by coupling this inter-

³⁶ Schultz, "Farbstofftabellen," 1914, p. 294.

mediate with thio-aniline. The couplings were made in the following way, as were also the acid colors described subsequently.

4. Diamine Bases with Various Intermediates

The dyes from thio-aniline, thio-aniline sulfone and the diamine from mustard gas when coupled with various intermediates are contrasted with those from benzidine. The colors are given in the following table.

TABLE XIV

Colors of Dyes from	CERTAIN DIAMIN	es Coupled	WITH VARIOUS	Intermediates
Acids	Benzidine	-S	-SO ₂ = (SCH ₂ CH ₂) ₂ S
Salicylic (chromed)	Yellow	Gold	Gold	Yellow
Schaeffer's salt	Maroon	Scarlet	Orange	Scarlet
Neville and Winth	er's Heliotrope	Red	Scarlet	Red
L-acid	Claret	Claret	Burnt orange	Red
R-salt	Purple	Claret	Burnt orange	Red
Chromotrope	Purple	Heliotrope	Claret	Heliotrope
Gamma-acid	Violet	Claret	Claret	Red
Chicago acid	Purple	Lilac	Maroon	Violet
H-acid	Blue	Purple	Maroon	Lilac

This series of colors indicates that where the diphenyl rings are separated by sulfur, sulfone and other groups, they no longer possess the properties of benzidine, which gives colors varying from deep reds to blues and violets. The thio-aniline and its sulfone give much lighter colors, differing slightly but practically in the same range of the spectrum as those obtained from the mono-amines coupled with the same acids, though the molecular weight is greater than that of the benzidine dyes and approximately double that of the mono-amine series. The dyes containing three sulfur atoms, with the mustard gas residue between, are also slightly lighter than those from thio-aniline.

In this series the sulfur divides the molecules, so that the colors obtained appear as if each half were acting as a unit, while with benzidine the effect of each group is felt in the opposite ring.

The three diamine bases having —SCH₂S—, —SCH₂CH₂S— and —SCH₂CH₂CH₂S— between the rings were coupled with gamma-acid. The dyes from the first two were red and practically identical, but the last gave a maroon.

The conclusion drawn above, that these diamine bases do not possess the properties of benzidine, is borne out by the fact that they do not form direct cotton dyes. Benzidine, coupled with gamma-acid or H-acid, forms colors which dye cotton direct from a salt bath. Those obtained from the three sulfide bases used in the previous series, when coupled with intermediates suitable for producing direct colors, are found to be lacking in this property. The benzidine dyes exhaust the bath completely, while the others do so only in part; some color, however, remains in the fibre. The

dyes from the trisulfide bases from mustard gas show some tendency towards being direct, as the colors do not wash out in cold water. The monosulfides are poorer, and in the case of the sulfones practically all of the color washes out in cold water. On the other hand, all of them are removed in boiling water.

Table XV gives the colors of these dyes on cotton. Here also the color effect produced by the sulfide and sulfone groups is the same as with the acid dyes described above.

TABLE XV

COLORS OF DYES FROM DIAMINE BASES COUPLED WITH SEVERAL INTERMEDIATES AND Dyed over Cotton

Intermediates	Benzidine	—S—	-SO ₂ =	(SCH ₂ CH ₂) ₂ S
Naphthionic acid	Red	Burnt orange	Burnt orange	Gold
Gamma-acid	Violet	Claret	Claret	Maroon
H-acid	Blue	Blue	Lilac	Violet

Summary

A series of bases, p-NH₂C₆H₄SR, has been made and these have been diazotized and coupled with R-salt to find the effect of changes in the radical R on the color. Dyes have been made from p-toluidine, p-anisidine, p-thioanisidine and its sulfone by diazotizing and coupling with a number of intermediates. It has been found that -SCH₃ > -OCH₃ > -CH₃ > -SO₂CH₃ act as auxochromes.

Diamine bases of the type ρ, ρ' -NH₂C₆H₄-X-C₆H₄NH₂ have been made in which X is -S-, -SO₂-, -SCH₂-, -SCH₂S-, -SCH₂CH₂S-, -SCH₂CH₂SCH₂CH₂S-, etc., and these were tetrazotized and coupled with various intermediates to find the effect of the group between the two rings on the color of the dves. These bases do not resemble benzidine in giving fast cotton dyes.

ARYL 1,3-BENZO-DIOXANES (ARYL METHYLENE-SALIGENINS)

By Roger Adams, A. W. Sloan and B. S. Taylor RECEIVED JUNE 11, 1923

In a contribution from this Laboratory on the structure of disalicyl aldehyde,1 it was shown that saligenin condensed readily with benzaldehyde to yield 2-phenyl-1,3-benzo-dioxane according to the following equation.

$$\begin{array}{ccc}
CH_2OH & + C_6H_5CHO \longrightarrow & & & \\
OH & & \\
OH$$

¹ Adams, Fogler and Kreger, This Journal, 44, 1126 (1922).

Since a condensation of this type has not been previously described a study has been made of the condensation of certain substituted benzaldehydes with saligenin and substituted saligenins. It has been found that the reaction is quite general and takes place with the greatest ease. Whereas it was necessary to have present a catalyst, such as a small amount of benzoic acid, when benzaldehyde condensed with saligenin, no catalyst was found necessary with the substituted compounds. Cinnamic aldehyde condensed like the aromatic aldehydes and it is probable that any α,β -unsaturated aldehyde will react similarly. Simple aliphatic aldehydes did not condense with saligenin to give dioxanes under similar conditions

The condensation to form dioxanes is a type of acetal formation and resembles the condensation of benzaldehyde with trimethylene glycol² or trimethylene glycol derivatives. The only difference is that in saligenin one of the hydroxyl groups is a phenol and the other is an alcohol. Since it has been shown that aromatic aldehydes form acetals with phenols under proper conditions, and these are intermediates in the formation of triphenyl methane compounds, it is not surprising that aromatic aldehydes condense with saligenin to form dioxanes. Apparently there is no tendency for the products formed to rearrange into triphenyl methane or analogous compounds.

The 2-aryl-1,3-benzo-dioxanes are formed in very good yields (60–95%). They are white crystalline compounds and, like simple acetals, very stable toward alkalies but unstable toward acids, with the formation of saligenin and aldehyde.

Experimental Part

General Method for the Preparation of 1,3-Benzo-dioxanes.—A mixture of 1 molecular equivalent of saligenin or substituted saligenin and benzaldehyde or substituted benzaldehyde was heated on a steam-bath until a homogeneous liquid resulted. This required generally 5 to 30 minutes but in the case of nitrobenzaldehyde and saligenin, almost 2 hours. After the heating, the reaction mixtures were allowed to stand at room temperature until they solidified, the time required varying from a few minutes to 8 to 10 hours. The resulting solids were washed with water and crystallized from alcohol. In the cases of benzaldehyde and saligenin and nitrobenzaldehyde and saligenin, benzoic acid was used as a catalyst. In these latter experiments, consequently, the reaction mixtures were washed with sodium carbonate and then with water before crystallization was attempted.

The condensation of nitrosaligenin with benzaldehyde and substituted benzaldehyde was attempted. No definite condensation products could be isolated and in one case apparently no reaction took place.

Cinnamic aldehyde and saligenin did not give a solid product.

Formaldehyde, acetaldehyde and butyraldehyde were condensed in succession with saligenin but in no case was a dioxan obtained.

Saligenin.—Saligenin was prepared by the reduction of salicyl aldehyde according to the method of Voorhees and Adams.³

Bromosaligenin,⁴ 5-Br-2-HOC₆H₄CH₂OH.—Bromosaligenin was prepared by a slight modification of the method of Auwers.

A solution was made of 50 g. (1 molecular equivalent) of saligenin in 2.5 liters of water in a 12-liter flask. This solution was cooled to $5-10^{\circ}$ and kept cold and stirred mechanically during the addition of 9 liters of bromine water containing 65 g. (1 molecular equivalent) of bromine, requiring about 2 hours. The solution was filtered to remove a small amount of tar and was then extracted with 3 to 4 liters of ether. After the ether had been dried it was distilled and a yellow liquid remained which solidified as it cooled. After crystallization from benzene there was obtained 44 g. of white plates which after a

³ Voorhees and Adams, This Journal, 44, 1397 (1922). See also Carothers and Adams, *ibid.*, 45, 1071 (1923).

⁴ Auwers and Büttner, Ann., 302, 131, 138 (1898).

second crystallization melted at 107-109°. This was used in the condensation mentioned above.

p-Homosaligenin, 5-CH₃-2-HOC₆H₄CH₂OH.—Homosaligenin is difficult to prepare by any of the methods now described in the literature. The best two are treating p-cresol with formaldehyde, and the reduction of homosalicylaldehyde with sodium amalgam. A most satisfactory method was reduction of homosalicylaldehyde with hydrogen and platinum oxide according to the general method described by Carothers and Adams.⁵

A solution of 27.2 g. of p-homosalicylaldehyde in 100 cc. of alcohol was treated with 0.23 g. of platinum oxide and 0.1 cc. of N ferrous chloride solution. The mixture was reduced in the usual way, the time required being about 40 minutes when the hydrogen was passed in under a pressure of about 1.5 atmospheres. The yield was quantitative. The platinum was filtered off, the solution was evaporated and the product recrystallized. It then melted at $105\,^{\circ}$.

Summary

- 1. It has been found that benzaldehyde and substituted benzaldehydes condense with saligenin and substituted saligenins to yield 2-aryl-1,3-benzo-dioxanes.
- 2. The condensations take place with the greatest ease and generally without the addition of a catalyst. In the case of benzaldehyde and saligenin, and of nitrobenzaldehyde and saligenin the presence of benzoic acid greatly speeded up the reaction and gave the best results.

PROPERTIES OF DYED MATERIALS

By H. WALES

RECEIVED JUNE 30, 1923

Absorption Spectrum and Its Relationship to Color

Ever since the discovery of artificial colors, attempts have been made to find some relationship between the color and the chemical constitution. For some classes of dyes theories have been worked out with fair success. In practically every case, however, the "color" has been determined by means of the position of the absorption band or bands as determined with a spectroscope.

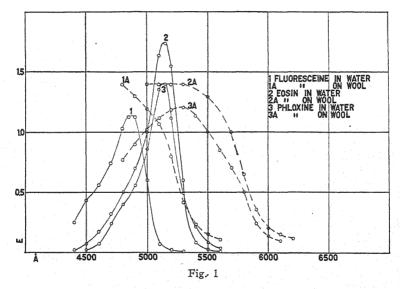

The author has been led to believe by some recent observations that this method is incorrect and that the location of the absorption maximum

⁵ Carothers and Adams, This Journal, 45, 1071 (1923).

¹ Ley, "Beziehungen zwischen Farbe und Konstitution," F. Hirzel, Leipsig, 1911. Watson, "Color in Relation to Chemical Constitution," Longmans, Green and Co., 1918.

or width of the absorption band as ordinarily determined has only a general influence on the color, that is, it will determine whether the color will be red or blue, but will not indicate the particular shade of red or blue. This fact was first brought out through solutions of Formyl Violet S4B and Acid Violet 4B Extra. The second solution was of a decidedly redder cast than the first, although it actually absorbed more red light, there being a shift in the absorption maximum of about 250 Å. towards the red end of the spectrum. Wool dyeings made from these two dyes showed the same color differences as the solutions.

Solutions of the majority of the dyes show broad absorption bands with indistinct maxima, due probably to isomers and subsidiary dyes. The yellows, browns, and most of the oranges are unsuited for spectroscopic work because their absorption is either in the ultraviolet or too

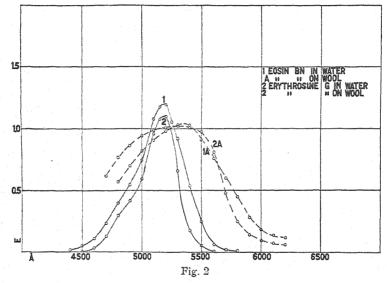

far into the violet to be read with any degree of accuracy. On the other hand, the dyes of the xanthene group show narrow, well-defined bands which fall near the center of the visual spectrum where the accuracy of reading is at the highest. Strangely enough, the one yellow dye of this group, fluoresceine, has its absorption maximum at about 4850 Å. and should therefore, by comparison with other dyes showing similar absorption, be orange-red.²

Since the matching of shades of color is at best subject to large personal errors due to the varying sensitivity of the eye in different individuals, a more absolute method had to be devised. It was found that the ab-

 $^{^{2}}$ The absorption maximum for Orange I is at 4750 Å, and for Ponceau 2 G at 4900 Å.

sorption spectra of wool dyed with different colors differed considerably from those determined from the solutions and offered at least a partial explanation for the color of the cloth.

The method used in this work was similar to that used by Meek and Watson.³ An attachment was fitted to the front of the photometer box of a Hilger spectrometer equipped with a Nutting photometer, to hold the cloth at an angle of 45° with the optical axis of the machine. By means of a suitable source of illumination, light was reflected from the dyed sample⁴ into one orifice of the photometer and from an undyed sample into the other orifice. A depth of dyeing sufficient to show an extinction coefficient of 1.0 to 1.5 was used in every case. This gave colorings of

almost equal intensity from dyes of different tinctorial strengths. Readings made on dyeings of different depths gave curves which were multiples of one another, although in many cases the samples would appear as entirely different shades to the eye. This is undoubtedly due to the varying sensitivity of the eye towards light of different wave lengths. The large amount of "white" light reflected from the surface of the cloth made it impossible to determine whether Beer's law held in this case.

The 17 dyes used in this work are listed in Table I. The absorption maxima were determined to the nearest 25 Å. for solutions and to the nearest 50 Å. for dyeings.

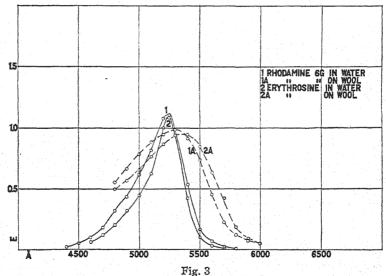

- ³ Meek and Watson, J. Chem. Soc., 109, 545 (1916).
- ⁴ All dyes used in this work were carefully purified and dyeings were made from aqueous solutions containing only the dye.
- ⁶ Compare Luckiesh, "Color and Its Applications," D. Van Nostrand Co., 1915, p. 11, on the effect of illumination.

Makers: "Berlin; "Schöllkopf; "Badische; "Heller; "Höchst; "National aniline; "Bayer.

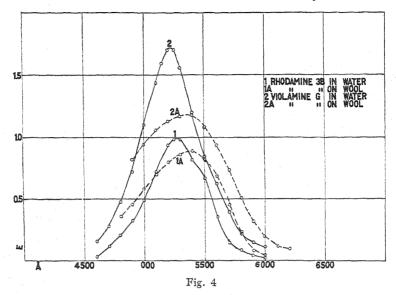

Eight of these dyes, Rhodamine 3B, Rhodamine 6G, Violamine G, Violamine R, Eosin BN, Erythrosine, Erythrosine G and Phloxine P, show absorption maxima in aqueous solutions at 5300 to 5200 Å. Disregarding the fluorescence, dilute solutions of 6 of these appear almost

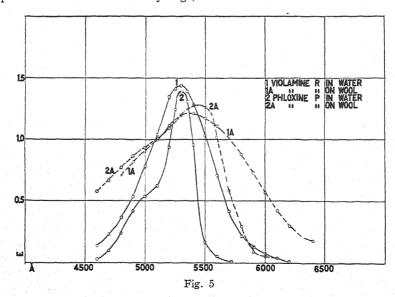

identical in color. Rhodamine 6G is slightly more yellow than these 6, while Violamine R, which shows practically the same absorption as Phloxine P, is decidedly purple. When dyeings are made from these 8 compounds, the series shows a gradual change in tint from a yellow-red to a blue-red. Violamine R still has the deepest color, but the yellowest shade is shown not by Rhodamine 6G but by Erythrosine G.

⁶ Schultz, "Farbstofftabellen," Weidmannsche Buchhandlung, 1914.

An analysis of the curves for the dyed samples shows that the complete curve and not the maximum determines the color. Erythrosine G and

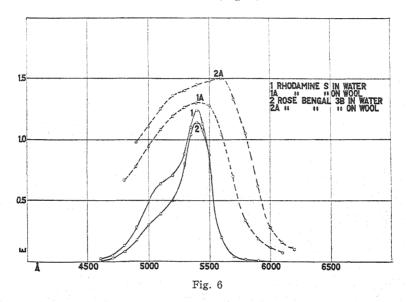

Eosin BN (Fig. 2) show maxima at practically the same point in both their aqueous solutions and wool dyeings, as do also Violamine R and Phloxine

P (Fig. 5). The first two show the same red absorption and the latter two the same blue absorption. Eosin BN, however, transmits more

blue light than Erythrosine G and is therefore bluer. In the same manner, the color of Violamine R is bluer than that of Phloxine P because it absorbs more light towards the red end of the spectrum.⁷

As was mentioned above, Acid Violet 4B extra has a much redder color than Formyl Violet S4B, although it shows a greater absorption in the red region. It also shows slightly more absorption in the blue but not enough to overbalance that in the red. Dyed samples show the same red absorption for both and a greater blue absorption for Acid Violet 4B Extra which is the redder of the two (Fig. 9).

The curves from the dyed samples show to a certain extent the color of an object. The spectrum of a solution will show only whether a dye should be red or blue. Anyone unfamiliar with the color of this solution would be unable to tell whether the unknown was lighter or darker in hue, by comparing its absorption curve with the spectrum of a known color giving a similar curve. Possibly either the absorption in the ultraviolet or in the infra-red or both may have some influence on the color sensation which is received by the eye. At present there are insufficient data on which to base any definite conclusions. A number of dyes have been studied to a limited extent in the ultraviolet, while only those used for sensitizing photographic plates have been examined for transmission in the infra-red.

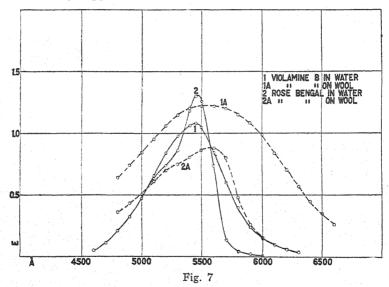

⁷ It is of interest to note that wool stained with alcoholic solutions of the color acids of these dyes gave curves identical with samples dyed from the salts.

^{*} Uhler and Wood, "Atlas of Absorption Spectra," Carnegie Inst. Washington, 1907.

The Mechanism of Dyeing

The older mechanical, chemical and solution theories of dyeing have of late been largely supplanted by the theory of colloidal adsorption by the fiber. The various methods which have been used to demonstrate these theories are incapable of direct proof. For this reason it was thought that a comparative spectroscopic investigation of dyes, both in solution and on the fiber, might shed some light on the subject.

Many investigators have noted that a dye will not show exactly the same absorption of light in two different solvents. Usually both the position of the maximum and the width of the band are altered with a change in solvent. It has also been claimed that the bands become wider as the dye approaches the colloidal condition. On the other hand,

the width of curves obtained from dye lakes¹¹ may or may not be different from those given by the corresponding dyes in aqueous solutions.

The spectrophotometric curves obtained from wool dyeings shown above are much broader than those from the aqueous or alcoholic solutions. When filter paper was stained with any of the xanthene dyes and examined by means of the spectroscope, absorption curves which were identical with those from wool dyeings were obtained, showing that the color is present on both fibers in the same state. Further experiments were made by depositing thin gelatin films of Eosin BN and Erythrosine on glass plates and measuring both the transmission and reflection spectra.

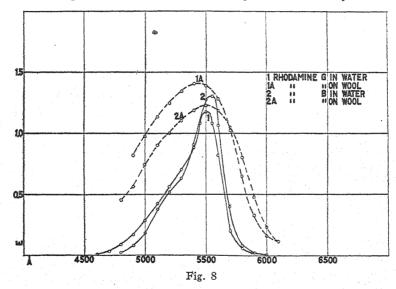

⁹ Bancroft, J. Phys. Chem., 18, 1, 118, 385 (1914); 19, 50, 145 (1915).

¹⁰ Shephard, Proc. Roy. Soc. London, 82A, 245 (1909).

¹¹ Holmes, Color Trade J., 13, 8 (1923).

In both cases the reflection spectra corresponded to those of the wool dyeings and the transmission spectra to those of the aqueous solutions, showing a slight shift in the maxima caused by a change in solvent (Fig. 10). Similar curves were obtained from a film of Erythrosine in cellulose acetate. These results indicate that these dyes are actually dissolved in the wool.

The objections to the solution theory¹² of dyeing are based mainly on the fact that the law of distribution between the solvent and fiber is not followed. Many dyeings are non-reversible.¹³ These objections, as well as most of the proofs put forth to substantiate the various theories, are based on the idea that dyes should act like inorganic or simple organic compounds in solutions. Since dyes do not obey the solution laws when dissolved in liquids, there is no reason to expect them to obey these laws

when dissolved in solids. For example, many sulfonated azo dyes can be completely extracted from aqueous solution by diluting with an equal volume of hydrochloric acid and shaking out with amyl alcohol. Repeated washings with 1:1 hydrochloric acid will not remove any of the dye from the amyl alcohol although the dye is very soluble in hydrochloric acid. When, however, the acidity of this amyl alcohol solution is reduced to below $0.7\ N$ by washing with dil. acid or with water, these dyes return to the aqueous layer. In this and many similar cases dyes show no distribution between two solvents. Under certain conditions the dye

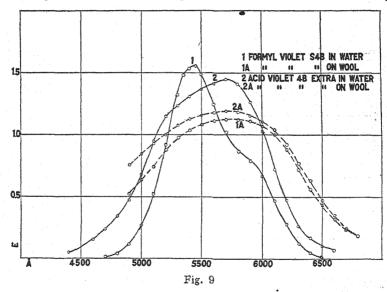

¹² Witt, Färbenztg., 1890-1891, 1.

¹³ Von Georgievics, Mitt. Tech. Gew. Museum Wien, 4, 205, 349; Z. angew. Chem., 16, 574 (1902).

¹⁴ U. S. Dept. Agr., Bull., 448, 12-13 (1917).

will go completely into one solvent and under slightly changed conditions into the other solvent.

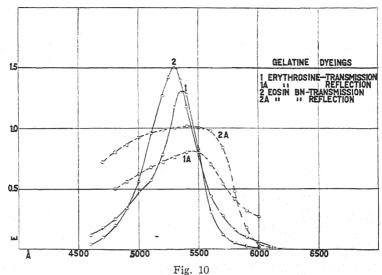

This failure to obey the solution laws may be due to the fact that most dyes are on the border line between the crystalloid and colloid states. This may be shown by some experiments which were conducted on the solubility of pure Tartrazine in water. If Tartrazine and water were placed in a thermostat and solution effected at the desired temperature, good checks on the solubility could be obtained. On the other hand, if solution of an excess of this dye was accomplished at a higher temperature, and then placed in the thermostat, precipitation would not always take place. In fact, many times the solution would continue to dissolve a large additional amount of Tartrazine at this lower temperature until finally some sort of a change in state would take place and an enormous amount of pre-

cipitation would occur. An entirely different value for the solubility of Tartrazine in water was given by this method from that found by the method first described. Many unexpected effects, due to the addition of slight amounts of sodium chloride, were also noticed and will be discussed in a later paper.

The properties of the dye and the fiber are such that a large and probably varying amount of dye would be adsorbed on the fiber in addition to that dissolved by it. For this reason it is extremely doubtful whether it will ever be possible to demonstrate the mechanism of dyeing satisfactorily by the methods which have been used in the past. A practice which cannot be too severely condemned in work of this nature is that of dyeing from solutions containing salts, acids or other leveling agents or assistants which

may cause secondary reactions on the fiber. Unfortunately, this point has been ignored by most investigators. A study of the literature yields a long record of tests made from solutions containing salt, Glauber's salt, sulfuric acid, soap, etc., and on samples which have been treated with various mordants. Attempts have been made to draw conclusions from the results thus obtained before the process of dyeing from solutions

containing only the pure dye has been fully studied. It would seem to be more scientific to investigate first the simple case where dye, fiber and solvent are the only factors concerned. After this has been done, the study of the effect of salt, etc., would follow.

The colloidal adsorption of dyes by the fiber has been successfully demonstrated by Bancroft¹⁶ and others, but most of the work shows that this cannot be the whole of the dyeing process. Some samples of paper pulp¹⁷ were dyed with Pontamine Sky Blue 3BX with the following results.

Table II

DISTRIBUTION OF DYE

¹⁶ Bancroft, "Applied Colloid Chemistry," McGraw-Hill Book Co., 1921.

¹⁷ Pulp obtained through the courtesy of the District of Columbia Paper Mfg. Co.

These results cannot be explained until some method is found of separating the adsorbed and unabsorbed dye on the fiber.

The optical method indicates that there is an actual solution of the dye in the fiber. The next step in explaining the mechanism of dyeing must be to find some method which will separate the dissolved dye from that held on the fiber by adsorption.

Summary

A study of the absorption spectra of light reflected from dyed materials showed that the reflection spectra more nearly explained the variations in color between two dyes than the transmission spectra of the solutions.

Dyeings made on wool, paper and gelatin indicated that the dye was present as a solution in these materials.

THE TEMPERATURE OF EXPLOSION FOR ENDOTHERMIC SUBSTANCES. II. TRINITRO-META-CRESOLATES AND THEIR EXPLOSION TEMPERATURES

By Rasik Lal Datta, Loknath Misra and Jogendra Chandra Bardhan Received July 2, 1923

The temperature of explosion has already been studied in the case of a few typical organic compounds, namely, nitro-bodies, picrates, azo compounds, haloid compounds, organic perchlorates, alkaloids, etc.¹ All of these classes of substances are endothermic and hence give explosion temperatures. Previous to our investigations, the explosion temperatures of a very few substances which explode before melting or decomposing were known and for endothermic substances generally such a temperature was never before known to exist. Several of the endothermic substances were, because of their practical use as explosives, known to explode by means of detonators and some of these were shown by Berthellot² to explode when thrown into a vessel previously raised to a high temperature.

The object of these investigations is to show that endothermic substances in general give an explosion temperature, and how the temperature varies according to the endothermic properties and molecular grouping. The reason why such an important constant has previously escaped detection is that substances which either melt or decompose at temperatures below the explosion temperature could not at all attain that temperature in the ordinary course of heating. The temperature is known only for those substances which explode before they are decomposed or volatilized.

¹ Datta and Chatterjee, *J. Chem. Soc.*, 115, 1006 (1919). Previous communication on the subject.

² Berthellot, Compt. rend., 105, 1159 (1887); 129, 926 (1899).

This is clearly evident when we examine how Silberrad and Phillips³ did not obtain the explosion temperatures of trinitrophenol and its ammonium, hydrazine and mercury salts, while they were successful with all the stable metallic salts of trinitrophenol which do not decompose or volatilize before the temperature of explosion is reached. The trinitrophenol is decomposed and the ammonium and hydrazine salts volatilized before the temperature of explosion is attained. This temperature can be determined in air, or in an atmosphere of inert gas such as carbon dioxide and nitrogen or in a vacuum. The method of determination as described in the previous communication on the subject was to drop small quantities of the substances to the bottom of a clean test-tube immersed in a bath of potassium hydrogen sulfate just when the temperature particular to each substance had been attained. The extreme accuracy and reliability of this temperature as an important physical constant for all endothermic substances will be evident from the practical determination of the explosion temperature of acenaphthene-trinitro-m-cresolate. This test was performed at 5°intervals from 350° to 450° without explosion, but at 455° the substance exploded. The bath was cooled, and tests were made at 445° and 450° without explosion, but at 452° explosion occurred. The bath was again cooled and tests made at 448° and 450° without explosion, but at 451° explosion occurred. Once more the bath was cooled and a test made at 450° without explosion, but at 451° explosion again took place. It is thus evident that the temperature of explosion is sharp and quite accurate; the explosion at 451° was marked by a vivid flash of light.

The temperature of explosion should be of great value in determining the purity of endothermic substances which do not give either a melting or a boiling point, since it has been found that the explosion temperature is elevated markedly in the presence of traces of moisture and other impurities. A perfectly pure substance gives the correct explosion temperature, just as it gives correct boiling and melting points.

Furthermore, this constant should be of great practical importance in the manufacture of explosives. It is generally a fact that the lower the temperature of explosion, the easier the substance is exploded and hence the smaller the charge of detonator needed. By determining the explosion temperature of a given explosive, the charges of detonator which would be necessary to explode it satisfactorily may be found at once by comparison with a known explosive having a similar temperature of explosion; no practical tests whatever should be necessary.

Experimental Part

In Table I are listed the names, formulas, properties, analyses, and explosion temperatures of 19 compounds with trinitro-m-cresol. The

compounds with acenaphthene, fluorene, allylamine, benzylamine, p-chloro-aniline and dimethyl- α -naphthylamine were obtained by mixing hot saturated solutions of the constituents and allowing the mixtures to cool slowly.

Camphylamine and α -naphthylamine were dissolved in dil. hydrochloric acid and mixed with hot saturated solutions of trinitro-m-cresolate in water. The menthylamine and piperazine derivatives were prepared from hot aqueous solutions. p-Bromo-aniline was dissolved in water and added hot to an alcoholic solution of the cresol, while alcohol was used for both solutions in the cases of p-iodo-aniline, o-anisidine, o-phenetidine, pseudo-cumidine, triphenyl-guanidine and α -naphthol. The hexamethylenetetramine and β -naphthol compounds were prepared by mixing hot aqueous solutions.

Our thanks are due to the Wolcott Gibbs and C. M. Warren Funds for grants which defrayed part of the expenses of the investigation.

Summary

The temperature of explosion of an endothermic organic explosive substance is a natural constant.

Addition compounds between 19 aromatic amines and phenols and trinitro-m-cresol have been prepared and their explosion temperatures determined.

STUDIES ON CELLULOSE CHEMISTRY

IV. PROPERTIES OF GAMMA-DELTA-DIHYDROXY-CARBONYL DERIVATIVES AND THEIR BEARING ON THE POLYMERIZATION OF POLYSACCHARIDES

By Harold Hibbert and John Arrend Timm^{1,2}
Received July 7, 1923

The suggestion was made by one of us some years ago³ that cellulose was probably derived from an anhydro glucose of the type of Formula I and this was termed the cellulose nucleus.

In a later paper⁴ a comprehensive review was made of the reactions to which any formula for cellulose must conform and opportunity was taken to emphasize the importance of the role played by the hydroxyl groups in the γ,δ positions to the —CHO radical.

- ¹ This paper is constructed from Part II of a dissertation presented by John Arrend Timm in June, 1922, to the Faculty of the Graduate School of Yale University in candidacy for the degree of Doctor of Philosophy.
- ² Communicated to the Cellulose Section, American Chemical Society, Birmingham, Alabama, April, 1922.
 - ³ Hibbert, Chem. Met. Eng., 22, 838 (1920).
 - ⁴ Hibbert, J. Ind. Eng. Chem., 13, 256, 334 (1921).

The question as to whether cellulose is merely a polymerized form of the above nucleus or consists of a closed ring containing (x) anhydro glucose molecules, as shown in Formula II, was left open, no definite information being available at that time as to the magnitude of (x).

That this view was clearly expressed is evident in the current literature. In view of Irvine's recent comments it should be pointed out that no claim has ever been made other than that the cellulose molecule in all probability consists of a large ring of anhydro glucose molecules, each connected to the other through the aldehydic and δ -hydroxyl oxygen linkages, respectively. This view was put forward at a time when no experimental data were available to either confirm or disprove such a theory and it is only through the brilliant series of investigations carried out by Irvine and his collaborators and pupils that the matter is now approaching a settlement, the evidence submitted strongly favoring the constitution of cellulose as represented by Formula III.

It is of interest that their work should confirm the speculations first put forward by one of us⁴ as to the mode of linking of the anhydro glucose units and of the fundamental importance of the γ,δ -hydroxyl groups in the glucose molecule.

If, as previously assumed, the polymerization of anhydro glucose to cellulose is fundamentally related to the behavior of, and dependent on, the loss of water from the δ - and aldehydic hydroxyls, then presumably other γ , δ -dihydroxy-carbonyl derivatives should exhibit the same behavior, and this is now found to be the case.

⁶ Irvine and Hirst, J. Chem. Soc., 123, 527 (1923).

Polymerization of γ , δ -Dihydroxybutyl-methyl Ketone.— γ , δ -Dihydroxybutyl-methyl ketone (CH₂OH—CHOH—CH₂—CH₂—CO—CH₃) was first prepared by Traube and Lehmann⁷ and is a pale yellow, viscous liquid which distils without decomposition at 190° under a pressure of 20 mm. Its mode of synthesis leaves no doubt as to the position of the hydroxyl groups relative to the carbonyl (CO) radical. When this ketone is heated at 120–130° in the presence of a trace of mineral acid (concd. sulfuric acid) for a few minutes, water is evolved and the liquid becomes more and more viscous, the dark-colored, very viscous product solidifying to a hard, compact resin at room temperature. This reaction also proceeds in the presence of this catalyst at room temperature, though much more slowly.

A determination of the amount of water evolved, and an analysis of the resin, show that the latter is derived from the dihydroxy ketone by the loss of one molecule of water from each molecule of the ketone. Assuming that the ketone possesses the butylene oxide structure⁸ the changes taking place may presumably be represented as follows:

⁷ Traube and Lehmann, Ber., 34, 1971 (1901).

⁸ The constitution of dihydroxybutyl-methyl ketone has not yet been definitely established. A decision as to whether it contains (a) a butylene or (b) an amylene oxide ring can presumably be reached by employing the technic developed by Irvine. Thus by converting it into the methyl ketoside, followed by methylation, hydrolysis, and oxidation (a) should yield a 1:4 diketone, while (b) should give a ketonic acid. This work is in progress as well as the synthesis of the corresponding aldehyde (CH₂-OHCHOHCH₂CH₂CHO), an examination of whose properties is expected to yield further valuable information. The senior author courteously requests that he may be left undisturbed in the prosecution of this work for a limited period.

the reaction thus representing an *intramolecular cyclic acetal condensation*. Such a reaction would seem to be of considerable importance when considered in the light of its bearing on the formation of inulin from fructose, starch and cellulose from glucose, etc.

There is one other explanation as to the course of the above reaction, namely, the primary splitting off of water to give an ethylene oxide ring,

followed by polymerization to the resinous product,

$$\begin{array}{c} \text{CH}_2\text{-CH}\text{-CH}_2\text{-CH}_2\text{-CO}\text{-CH}_3 \\ \text{CH}_2\text{-CH}\text{-CH}_2\text{-CH}_2\text{-CO}\text{-CH}_3 \\ \text{O} \end{array} \\ \begin{array}{c} \text{CH}_2\text{-CH}\text{-CH}_2\text{-CH}_2\text{-CO}\text{-CH}_3 \\ \text{O} \\ \text{O} \\ \text{O} \end{array} \\ \begin{bmatrix} \text{CH}_2\text{-CH}\text{-CH}_2\text{-CH}_2\text{-CO}\text{-CH}_3 \\ \text{O} \\ \text{O} \\ \end{bmatrix}_X \end{array}$$

That this does not occur was proved by the direct synthesis of B from allyl acetone by treating the latter with hypochlorous acid to give the chlorohydrin and then removing hydrochloric acid with formation of the oxide, which was first prepared in this manner by Kablukow, (B). On warming with a drop of concd. sulfuric acid, this oxide shows no tendency to polymerize, prolonged heating resulting only in charring.

The results thus obtained provide valuable experimental support for previous speculations relative to the role played by hydroxyl groups in the γ and δ positions to the carbonyl radical and of their function in the polymerization processes leading to the formation of polysaccharides. The importance of these groups is being further emphasized by Irvine and his school in connection with the properties of the γ sugars as related to vital problems such as the abnormal metabolic changes taking place in cases of diabetes.

Experimental Part

Preparation of γ , δ -Dihydroxybutyl-methyl Ketone.—The ketone was prepared by the method of Traube and Lehmann⁷ by heating together epichlorohydrin and the sodium salt of ethyl aceto-acetate. The sodium salt of 1-chloro-2-hydroxypropyl-ethyl aceto-acetate, first formed, decomposes, yielding sodium ethylate and α -acetyl- δ -chloro- γ -valerolactone. The lactone, on boiling with a dilute solution of potassium carbonate, yields the γ , δ -dihydroxybutyl-methyl ketone.

Method.—Twelve g. of sodium was dissolved in absolute alcohol and 70 g. of aceto-acetic ester added. The mixture was cooled to 0° and 50 g. of epichlorohydrin, dissolved in 50 cc. of absolute alcohol, was added drop by drop in the course of about two hours. The alcohol was then evaporated under reduced pressure and the residue treated with 500 cc. of 5% sulfuric acid. The oily layer which separated was dried over sodium

⁹ Kablukow, J. Russ. Phys.-chem. Soc., 1, 502 (1887); Ber. Ref., 21, 55 (1888).

sulfate and, on fractionation under reduced pressure, yielded 40 g. of the lactone, b. p., 163° (12 mm.), which corresponds to that obtained by Traube and Lehmann.

Forty g. of α -acetyl- δ -chloro- γ -valerolactone was boiled with 0.5 mole of potassium carbonate in the form of a 5% aqueous solution for 5 hours. The oil gradually dissolved with evolution of carbon dioxide. After removal of the water under reduced pressure at about 25°, the remaining oil was dissolved in absolute alcohol, the solution filtered from the potassium chloride, dried over sodium sulfate, and the alcohol removed by distillation. The remaining oil, on fractionation, yielded 8 g. of γ , δ -dihydroxybutylmethyl ketone, b. p., 158–160° (7–8 mm.) [b. p., 189–191° (20 mm.)], which is in agreement with that found by Traube and Lehmann).

Conversion of Dihydroxybutyl-methyl Ketone into its Anhydro Derivative.—Prepared as outlined above, the dihydroxy ketone is a pale yellow, viscous liquid which distils under diminished pressure without decomposition if all traces of acid are carefully removed. It also undergoes no apparent change after standing at room temperature for months. However, when it is heated under atmospheric pressure in the presence of traces of concd. sulfuric acid at about 125°, dehydration followed by resinification takes place.

Fifty g. of dihydroxybutyl-methyl ketone was mixed with 0.05 g. of concd. sulfuric acid and the mixture heated to 150° . The liquid rapidly became very viscous, water was evolved and after 2–3 minutes it solidified on cooling to a hard resin. This was pulverized, dried for two hours at 100° , and analyzed.

Analyses. Calc. for $C_6H_{10}O_2$: C, 63.11; H, 8.84. Found: C, 62.86, 62.91; H, 9.01, 9.11.

The analysis indicates that the product has been formed by the loss of one mol. of water from each molecule of the dihydroxybutyl-methyl ketone ($C_6H_{12}O_3 = C_6H_{10}O_2 + H_2O$), a conclusion confirmed by the direct weighing of the water evolved during the resinification process.

This was carried out by placing a known weight of the ketone in a small glass-stoppered tube (about 8 cc. in capacity, 10 cm. long and 1 cm. in diameter). This was fitted with a narrow inlet and outlet tube, the latter being connected to a weighed U-tube containing concd. sulfuric acid; 0.01 g. of concd. sulfuric acid was then introduced, the stopper inserted and the mixture heated to 120–130° in a current of dry air for about 6 hours to constant weight.

Analysis. Subs., 0.7956: H_2O obt. 0.1177; actual loss in weight of ketone product, 0.1337 g., or 16.8%. Calc. for 1 molecule loss of water: H_2O , 13.64%. Found: 14.79.

There is apparently some slight secondary decomposition brought about by the long continued heating under these conditions.

Preparation of γ -Ketobutyl-ethylene Oxide. CH_2 -CH- CH_2 - CH_2 -

CO—CH₃.—This was made according to Kablukow's method⁹ from allyl acetone.

Allyl Acetone.—Allyl acetone was obtained by condensing allyl bromide with the sodium salt of aceto-acetic ester¹⁰ and saponifying the allyl-ethyl aceto-acetate, thus formed, with dil. potassium carbonate solution.

¹⁰ Wolff, Ann., 201, 46 (1880).

Mehrling's¹¹ method of hydrolysis with barium hydroxide was found unsatisfactory. The following modified procedure gave satisfactory results, but the yield was never high because of the formation of by-products.

One hundred g. of allyl-ethyl aceto-acetate was boiled for 20 hours with 300 cc. of a 5% potassium carbonate solution, the mixture being thoroughly agitated throughout. The product was then steam distilled, the upper allyl acetone layer in the distillate separated and the aqueous layer extracted with ether. The ether extract was dried over sodium sulfate and finally distilled. Yields of about 35% allyl acetone (b. p., $129-134^\circ$) were usually obtained.

Allyl Acetone Chlorohydrin.—The hypochlorous acid solution was prepared according to the method of Bamberger and Lodter. 12

Two hundred g. of bleaching powder was suspended in water and allowed to stand for 24 hours in the dark at 40° , 115 g. of sodium carbonate was then introduced and the suspension thoroughly shaken. It was then filtered by suction and 160 g. of pulverized boric acid added to the filtrate.

To 100 cc. of this solution, 10 g. of allyl acetone was slowly added in the course of one hour, the mixture being agitated and the temperature kept below 0°. The solution was also protected from direct light. After standing for 12 hours another 200 cc. of the hypochlorous acid solution was added and the solution allowed to stand under the same conditions for an equal length of time. It was then extracted with ether, dried over sodium sulfate, the ether removed, and the remaining oil fractionated under reduced pressure; yield, 8 g.; b. p., 113° (20 mm.), which corresponds to that obtained by Kablukow.

Conversion of the Chlorohydrin into the Oxide.—Eight g. of allyl acetone chlorohydrin was heated with 200 cc. of 5% potassium carbonate solution on a water-bath for 16 hours and then at the boiling point on a sand-bath for 10 hours. The solution was cooled, extracted with ether, dried, and the ether removed by distillation. No residue remained. The mother liquor was then carefully neutralized with hydrochloric acid and the water evaporated on a steam-bath. A viscous oil remained which was dissolved in alcohol, filtered, and dried over sodium sulfate; the alcohol was then removed, and the residue distilled under diminished pressure. The oxide was obtained as a colorless, mobile liquid; b. p., 169° (81 mm.); yield, about 2 g.; the boiling point recorded by Kablukow was 162–167° at 80 mm. When a portion of the oxide was heated with a drop of concd. sulfuric acid no indication of any polymerization could be observed, but prolonged heating resulted in some charring.

The authors desire to acknowledge gratefully the kind assistance rendered them for the purchase of supplies in the form of a grant from the Warren Fund of the American Academy of Arts and Sciences.

Summary

- 1. Attention is drawn to the important role played by the γ and δ -hydroxyl groups in the conversion of carbohydrates to polysaccharides.
- 2. It is found that the simplest γ, δ -dihydroxy-ketone, namely, γ, δ -dihydroxybutyl-methyl ketone, readily undergoes dehydration and polymerization in the presence of a trace of mineral acid. The change corre-

¹¹ Mehrling, Ann., 264, 323 (1891).

¹² Bamberger and Lodter, Ann., 288, 81 (1895).

sponds to a loss of one molecule of water from each molecule of the dihydroxy ketone.

3. The polymerization taking place is probably closely related to that occurring in the formation of inulin from fructose.

TRIHYDROXY-METHYL-ANTHRAQUINONES. 1

By G. D. Graves¹ with Roger Adams Received July 23, 1923

Hydroxy-methyl-anthraquinones and their methyl ethers occur widely, either in the free state or as glucosides, in the leaves, bark and roots of various plants, forming natural drugs and coloring matters. Six natural trihydroxy-methyl-anthraquinones have been reported in the literature, the most important being emodin, found in Cascara sagrada, Frangula, rhubarb and other plants. The probable structures which have been suggested for a few of these anthraquinones contain two hydroxyl groups in one ring, with the methyl and remaining hydroxyl in the other. A study of a practical method of synthesis of this type of substituted anthraquinones has been undertaken with the ultimate object of synthesizing the natural products.

In general, the best method available for the preparation of substituted anthraquinones with definite structures is the condensation of phthalic anhydride or its derivatives with benzene derivatives to form substituted benzoyl-benzoic acids; these can then be dehydrated to give anthraquinones. To prepare the desired trihydroxy-methyl-anthraquinones it was proposed to condense dimethoxy-phthalic anhydrides with the cresols, to dehydrate the resulting benzoyl-benzoic acids, and to demethylate the anthraquinones.

But few condensations involving methoxy-phthalic anhydrides have been reported. Bistrazycki² condensed 3,4-dimethoxy-phthalic anhydride (hemipinic anhydride) with anisole by means of aluminum chloride, using benzene as a solvent. The same anhydride was condensed by Weizmann³ with veratrol, pyrogallol-trimethyl ether and o-xylene, using aluminum chloride with carbon disulfide as a solvent. Simonsen condensed this anhydride with o-cresol by means of aluminum chloride in acetylene tetrachloride.⁴ With the exception of the condensation product of hemipinic anhydride with anisole, the exact structure of the resulting products

¹ This communication is an abstract of a thesis submitted by G. D. Graves, DuPont Fellow for 1922–1923, in partial fulfilment of the requirements for the Degree of Doctor of Philosophy in Chemistry at the University of Illinois.

⁴ Simonsen, ibid., 119, 1339 (1921).

was not determined. In the particular case just mentioned it was shown without question that the carboxyl group adjacent to the methoxy group entered into reaction and that it condensed *para* to the methoxy group of the anisol.

Weizmann³ condensed 4-methoxy-phthalic anhydride with o-xylene and p-cresol methyl ether by means of aluminum chloride in carbon disulfide, and with the free cresols by means of boric acid; Dimroth and Fick⁵ condensed 3-methyl-5-methoxy-phthalic anhydride with hydroxy-hydroquinone triacetate by means of boric acid. The exact course of these condensations was also left undetermined. Moreover, in almost all of the condensations just reviewed the results were quite unsatisfactory.

A systematic study of the synthesis of such trihydroxy-methyl-anthraquinones of definite structures from methoxy-phthalic anhydrides must involve a thorough knowledge of four points: the best method for the initial condensation to form the benzoyl-benzoic acid derivatives; the best method for dehydrating the benzoyl-benzoic acids to form anthraquinones; the position in the cresol ring (whether *ortho* or *para* to the hydroxyl) taken by the entering benzoyl radical; the determination of which of the two carboxyl groups in an unsymmetrical phthalic anhydride reacts first with the cresol.

This research has involved a study of the condensation of 3,6-dimethoxy-phthalic anhydride with o-, m- and p-cresols. The structure of the benzoyl-benzoic acids formed has been determined and a study of their conversion into anthraquinones has been made. Preliminary work upon the condensation of 3,5-dimethoxy-phthalic anhydrides and cresols has been carried out.

On account of its ease of preparation, 3,6-dimethoxy-phthalic anhydride was chosen as a convenient methoxy-phthalic anhydride to employ in determining a satisfactory method of condensation with the various cresols. It has the further advantage of being symmetrical in structure, thereby eliminating a problem which is involved with unsymmetrical phthalic anhydrides, namely, the determination of which carboxyl reacts first with the cresol.

Many of the commoner methods of effecting condensation of phthalic anhydrides with various types of cresols gave unsatisfactory results with the 3,6-dimethoxy derivative. Thus, boric acid gave very poor yields, and the method of Ullmann and Schmidt,⁶ using aluminum chloride and acetylene tetrachloride, caused the decomposition of the anhydride. Satisfactory results were obtained by using excess of cresol as a solvent⁷ and a rather

- ⁵ Dimroth and Fick, Ann., 411, 315 (1915).
- ⁶ Ullmann and Schmidt, Ber., 52, 2098 (1919).

⁷ During the preparation of this manuscript an article has appeared by Widmer [Helvetica Chim. Acta, 6, 421 (1923)] in which a similar method of condensation of certain phthalic anhydrides with phenols was employed with success.

large proportion of aluminum chloride. Under these conditions consistent results were obtained. 3,6-Dimethoxy-phthalic anhydride formed benzoyl-benzoic acid derivatives when condensed with the cresols and at the same time yielded diphenyl-phthalide derivatives as by-products.

Acids I, II and III were obtained from o-, m- and p-cresols in 22%, 50% and 16% yields, respectively. In each reaction, a certain amount of diphenyl-phthalide derivative formed, a phthalein from both o- and m-cresol (IV and V) and a fluoran from p-cresol (VI).

Although the yields of benzoyl-benzoic acids appear small, the ease with which they could be separated and purified rendered the processes practicable.

For the dehydration of the benzoyl-benzoic acids to form anthraquinones, concd. or fuming sulfuric acid, sometimes with boric acid, has almost always been used. These reagents have proved satisfactory for many of the methoxy compounds studied. Concd. sulfuric acid with a trace of boric acid readily converted the condensation products from o- and p-cresol (I and III) into the corresponding anthraquinones (VII and IX) in 30% and 88% yields, respectively. In the case of the m-cresol, however, ordinary concd. sulfuric acid gave no results and only by the use of 7% fuming acid was it possible to obtain a 6% yield of the corresponding anthraquinone (VIII).

A similar difficulty in the formation of anthraquinones from those benzoylbenzoic acids which contain an *ortho* or *para* directing group *meta* to the position in which condensation must take place was observed by Weizmann.⁸ This difficulty was particularly pronounced in the case of phenol derivatives probably on account of the ease with which sulfonation took place. Widmer⁹ reports the formation of an anthraquinone from a *m*-cresol-benzoyl-benzoic acid by means of fuming sulfuric acid, but does not state his yield.

Under the conditions used for forming the anthraquinones from the benzoyl-benzoic acids, there was only a slight splitting of the methyl ethers during the condensation. In general, if temperatures higher than 100° were employed, the splitting of the ethers became appreciable and sulfonation took place to a greater extent. For the conversion of the methylated anthraquinones to the corresponding hydroxy anthraquinones (X, XI and XII), aluminum chloride in benzene may be used. It was found, however, that better results could be obtained by heating with constant-boiling hydrobromic acid in acetic acid solution.

The structure of the benzoyl-benzoic acids was determined by a comparison of the compounds obtained from the free cresols and the cresol ethers. The assumption was made that the entering group would be either ortho or para to the hydroxyl, since no condensations of this type have ever been known to enter the meta position. Nourrisson¹⁰ and Weizmann³ have already shown in a number of instances that phthalic anhydride and certain derivatives condensed with phenol ethers in the para position to the methoxyl group. Other investigators 11 have found that with free phenols the entering group goes ortho to the hydroxyl. By analogy, it seems reasonably certain that the structures of the compounds obtained in this investigation are correct as given. To confirm this conclusion the benzoyl-benzoic acids from 3,6-dimethoxy-phthalic anhydride and o- and m-cresols were methylated to give the trimethyl ethers. These products differed from the trimethyl ethers¹² obtained by the condensation of phthalic anhydride and cresol ethers, showing definitely that a different position was taken in each of the condensations. The condensation product from p-cresol, when methylated, gave the same substance as that obtained by the condensation product from p-cresol methyl ether. This would be expected because the para positions to the hydroxyl and methoxyl

groups in p-cresol and p-cresol methyl ether, respectively, are filled, and consequently the *ortho* position will be taken in both condensations.

Further evidence concerning the character of the condensation products came from a study of the decomposition of the phthaleins. It has already been mentioned that when the cresols were condensed with 3,6-dimethoxy-phthalic anhydride, diphenyl-phthalide by-products were obtained. The phthaleins from the o- and m-cresol condensations resemble phenol- and cresolphthalein very closely and the products, therefore, unquestionably have the structure represented by Formulas IV and V. In the case of the p-cresol, phthalein condensation must take place in the ortho position to the hydroxyl, thus allowing the formation of a fluoran by dehydration (VI). If, for any reason, the phthaleins had formed in the ortho position to the hydroxyl in either the o- or m-cresol condensations, it is extremely probable that fluorans would also have formed spontaneously.

The phthalein (IV) from the o-cresol condensation, when heated with 3,6-dimethoxy-phthalic anhydride in sulfuric acid, was converted according to the general method of Baeyer¹³ into an anthraquinone derivative. This anthraquinone (XIII), however, should be different from that (X) obtained by the dehydration of the benzoyl-benzoic acid from 3,6-dimethoxy-phthalic anhydride and the free o-cresol and then demethylation of the anthraquinone produced; but it should be identical with the trihydroxy-methyl-anthraquinone¹⁴ formed by the condensation of 3,6-dimethoxy-phthalic anhydride with o-cresol methyl ether, followed by condensation to the anthraquinone and demethylation.

The experimental results were exactly those expected, the substances obtained checking up in every particular. The fact that the anthraquinone formed according to the above equation has the structure XIII and not the possible isomeric structure XIV is proved in the following paper.¹⁴

The condensation of 3.5-dimethoxy-phthalic anhydride and m-cresol (XV) was carried out. It went smoothly as might be expected from the

¹³ Baeyer and Freude, Ann., 202, 137, 165 (1880).

¹⁴ Gardner and Adams, This Journal, 45, 2455 (1923).

results with the 3,6-dimethoxy-phthalic anhydride and *m*-cresol. It seems probable that the condensation took place through the carboxyl adjacent to the methoxyl group judging by analogy to hemipinic anhydride condensations, but this has not yet been proved.

In order to show that condensation with the 3,5-dimethoxy-phthalic anhydride followed the same course as the condensation with 3,6-dimethoxy-phthalic anhydride, that is ortho to the hydroxyl and para to the methoxyl. 3,5-dimethoxy-phthalic anhydride was condensed with m-cresol methyl ether. A different trimethoxy-benzoyl-benzoic acid (XVI) was obtained from that formed by the methylation of the condensation product XV obtained from the free m-cresol. Proof of the structure of the condensation products was indicated by condensing 3.5dimethoxy-phthalic anhydride with o-nitro-m-cresol, obtaining undoubtedly the acid XVIII because there would be practically no tendency for the benzovl group to enter between the hydroxyl and methyl groups, and the other ortho position to the hydroxyl group is filled. This was not identical with the nitration product from the acid XV which, doubtless, then has the structure XIX. Had condensation with m-cresol gone para to the hydroxyl group to form the acid XVII, nitration would undoubtedly have given the acid XVIII.

The condensation product of 3,5-dimethoxy-phthalic anhydride and *m*-cresol (XV) should by dehydration and demethylation give emodin, provided the structure¹⁵ XX which has been assigned to it after a careful study of its reactions is correct. When the ring closure was attempted, however, even poorer yields were obtained than with the *m*-cresol condensation product from 3,6-dimethoxy-phthalic anhydride. The product was methylated to form the trimethyl ether and this was compared with the trimethyl ether from emodin. Natural emodine and the synthesized dimethyl ether dissolved in alkali with the development of & red color. The synthetic trimethyl ether and that from cascara emodin dissolved

¹⁵ Arch. Pharm., 250, 301 (1912). Hesse [Ann., 309, 73 (1899)] had previously suggested that emodin might have the structure of the anthraquinone (XII) prepared as described above.

in concd. sulfuric acid with the same red color. The absorption spectra of the trimethyl ethers showed close similarity in their curves.

Although only a very small amount of the anthraquinone was obtained, all indications pointed toward its being an emodine derivative. Further work is now under way modifying this latter condensation in such a manner that the preparation of emodine in satisfactory yields should be possible and the constitution of this substance thus be proved without question.

Absorption Spectra of the Anthraquinones and Phthaleins 16

The absorption spectra and color reactions of anthraquinones are accepted as furnishing very reliable evidence concerning the orientation of hydroxyl groups. Absorption-spectra curves for all of the anthraquinones prepared were obtained by the method recommended by the United States Bureau of Standards. As abscissas are plotted wave lengths in $(m\mu)$ and as ordinates, $-\log_{10}$ transmission, which is defined as the ratio of the intensities of the light leaving to the light entering the absorbing layer, that is, $bck = -\log T$, where b is the concentration and c the thickness. The concentration of the solutions used was not determined so that the values of the ordinates have no significance; this does not interfere with the determination of the wave length of the absorption bands.

The absorption of slightly acid and alkaline alcoholic solutions was determined, the alcohol being used to accentuate the peaks of the curves. The solutions for determination were prepared by adding to the alcoholic solutions of the anthraquinones just enough alcoholic alkali to change the color, or a drop of alcoholic hydrochloric acid. All of the curves of the anthraquinones having the quinizarin grouping (two α -hydroxyl groups in the same ring) have the same general form, the acid absorption band being nearer the blue than the alkaline band (Fig. 1). The maxima of the dimethoxy-hydroxymethyl-anthraquinones were 15-20m μ nearer the blue than those of the corresponding trihydroxy compounds (Fig. 2). The bands shifted toward the red in the 1,5,8-trihydroxy-anthraquinones as the methyl group moved from Position 2 to 4 to 3.

The phthaleins (IV and V) are very similar to phenolphthalein, giving blue-red colors with alkali. They are indicators, changing color at $P_{\rm H}$ values of 9.1 and 9.8, respectively, phenolphthalein and o-cresolphthalein changing at Sörensen values of 8.3 and 8.2, respectively.

The alkaline absorption curves were very similar, Phthaleins V and VI showing maxima at $\lambda 580$ and $\lambda 585$, respectively, while the maxima of

¹⁹ Meek, J. Chem. Soc., 109, 554 (1916).

phenolphthalein and o-cresolphthalein are at $\lambda555$ and $\lambda572$, respectively. The curves are of the same general type as that obtained from phenolphthalein.

means of sulfuric acid. The phthalimide was converted to the anhydride by alcohol and hydrochloric acid.

The same results could not be obtained by following the directions given. It has been found possible to convert the nitrile directly to the anhydride by means of sulfuric acid.

²² All melting points given in this paper are corrected unless otherwise stated.

²² Ref. 21. Zincke and Schmidt [Ann., 286, 37 (1895)] also obtained this anhydride by oxidation of 1,4,5,6-tetramethoxy-naphthalene with potassium permanganate.

A mixture of 60 g. of crude dicyanohydroquinone dimethyl ether, 300 cc. of concd. sulfuric acid, and 15 cc. of water was heated on the steam-bath for 1.5 hours. At the end of this time the solution was poured into 500 cc. of water and boiled for two hours. After the mixture had cooled the dimethoxy-phthalic anhydride was filtered off. The yield was 45 g. (64%) when the 2,3-dicyanohydroquinone dimethyl ether was of reasonably good grade. The product, after purification from benzene, melted at 259–261°. Sometimes the total amount did not precipitate at once. It was often necessary to evaporate the filtrate in an open dish overnight on the steam-cone in order to complete the hydrolysis of the nitrile. On the addition of water, the remainder of the anhydride was precipitated.

Condensation of 3,6-Dimethoxy-phthalic Anhydride with the Cresols

p-Cresol Derivatives. 3,6-Dimethoxy-2-(2-hydroxy-5-methylbenzoyl)benzoic Acid (III).—A mixture of 10 g. of 3,6-dimethoxy-phthalic anhydride, 10 g. of aluminum chloride, and 30 cc. of p-cresol was stirred mechanically and heated slowly up to 70° (oil-bath temperature) during the course of 4 hours, then held at that temperature for 9 hours. Water was cautiously added to decompose the excess of aluminum chloride, then 10 cc. of hydrochloric acid, and the excess of cresol was distilled with steam. The liquid remaining in the flask was decanted from the gummy residue which was dissolved in 10% sodium hydroxide solution. The alkaline solution was red, due to phthalein byproducts. It was saturated with carbon dioxide to precipitate the phthalein (2 g.), which was filtered off. The filtrate was acidified with hydrochloric acid to precipitate the benzoylbenzoic acid; yield, 2.5 g. (16%). The product was purified from methyl alcohol, forming white plates; m. p., 218°.

Analyses. Subs., 0.1330; CO₂, 0.3146; H₂O, 0.0620. Cale. for $C_{17}H_{16}O_6$: C, 64.59; H, 5.06. Found: C, 64.51; H, 5.17.

Subs., 0.2243: required, 0.712 cc. of N NaOH. Calc.: neutr. equiv., 316. Found: 315.

2,7-Dimethyl-12,15-dimethoxyfluoran²⁴ (VI).—The phthalein by-product was dissolved in glacial acetic acid. The solution was treated with bone black and allowed to stand in the open for a week or more in order to avoid the separation of amorphous material by rapid precipitation and to allow crystals to form slowly. This material was recrystallized from glacial acetic acid, from dil. acetic acid, and from an acetone-ether mixture, to constant melting point. It was found to be insoluble in alkali, the acetic acid apparently having dehydrated the *ortho*-phthalein to a fluoran. The product formed white crystals that melted at 290°.

Analyses. Subs., 0.0791, 0.1029: CO_2 , 0.2128, 0.2771; H_2O , 0.0378, 0.0493. Calc. for $C_{24}H_{20}O_5$: C, 74.22; H, 5.16. Found: C, 73.37, 73.43; H, 5.30, 5.32.

The material analyzed had not undergone the final purification with acetone and ether and apparently held acetic acid, so that the analyses were not as accurate as might be expected.

About 4 g. of uncondensed dimethoxy-phthalic anhydride was recovered by adding $^{1}/_{3}$ the volume of sulfuric acid to the liquors remaining over the gummy condensation product after steam distillation, and boiling the solution until the anhydride separated. Thus, from the 6 g. of anhydride that reacted, 4.5 g. of mixed product was isolated.

3,6-Dimethoxy-2-(2-methoxy-5-methylbenzoyl)benzoic Acid.—This substance was prepared in quantitative yields by refluxing 1 g. of the 3,6-dimethoxy-2-(2-hydroxy-5-methylbenzoyl)benzoic acid (III), 4 g. of potassium hydroxide, 5 g. of dimethyl sulfate and 75 cc. of water for an hour, filtering, and precipitating the trimethoxy compound with hydrochloric acid. It was recrystallized from dil. methyl alcohol, forming white

²⁴ The nomenclature used is that recommended by Chemical Abstracts.

needles that melted at 203° . It proved to be identical with the compound made from 3,6-dimethoxy-phthalic anhydride and p-cresol methyl ether and described in the following paper by Gardner and Adams.

1-Hydroxy-4-methyl-5,8-dimethoxy-anthraquinone (IX).—Two g. of the 3,6-dimethoxy-2-(2-hydroxy-5-methylbenzoyl)benzoic acid (III), a pinch of boric acid, and 40 cc. of concd. sulfuric acid were heated on the steam-bath for one hour. The color changed from green to bluish red. The solution was poured over ice to precipitate the anthraquinone. It was purified by dissolving in alkali and reprecipitating with carbon dioxide; yield, 1.5 g. (88% of the calculated amount). The material was purified from acetone, forming red needles; m. p., 224°. It gave a red solution in alkali and a blue to blue-red color in concd. sulfuric acid, depending on the concentration.

Analyses. Subs., 0.0620: CO_2 , 0.1566; H_2O , 0.0247. Calc. for $C_{17}H_{14}O_5$: C, 68.46; H, 4.70. Found: C, 68.89; H, 4.47.

1,5,8-Trihydroxy-4-methyl-anthraquinone (XII).—1-Hydroxy-4-methyl-5,8-dimethoxy-anthraquinone (IX) was refluxed with equal parts of constant-boiling hydrobromic acid and glacial acetic acid for 6 hours. The anthraquinone was precipitated by pouring the solution into water and purified by recrystallization from glacial acetic acid. It dissolved in alkali with the development of a blue-red color. In concd. sulfuric acid it showed a blue color in dilute solutions, and a blue-red color in greater concentrations.

Analyses. Subs., 0.0734: CO₂, 0.1784; H_2O , 0.0250. Calc. for $C_{15}H_{10}O_5$: C, 66.66; H, 3.70. Found: C, 66.29; H, 3.78.

o-Cresol Derivatives. 3,6-Dimethoxy-2-(2-hydroxy-3-methylbenzoyl)benzoic Acid (I).—A mixture of 15 g. of 3,6-dimethoxy-phthalic anhydride, 24 g. of aluminum chloride and 60 cc. of o-cresol, stirred mechanically, was heated in an oil-bath at 75 $^{\circ}$ for 19 hours. The products were worked up as in the p-cresol condensation: yield, 5 g. of benzoyl-benzoic acid (22%) and 18 g. of crude phthalein by-product. The benzoyl-benzoic acid was purified from methyl alcohol, forming white needles; m. p., 194°.

Analyses. Subs., 0.0748: CO_2 , 0.1958; H_2O , 0.0352. Calc. for $C_{24}H_{22}O_6$: C, 70.33; H, 5.17. Found: C, 71.02; H, 5.22.

o-Cresol-3,6-dimethoxy-phthalein (2,2-Bis(4-hydroxy-5-methylphenyl)3,6-dimethoxyphthalide) (IV).—This substance was purified in the same way as was 2,7-dimethyl-12,15-dimethoxy-fluoran (VI). It was treated, however, with hot alkali after recrystal-lization from acetic acid in order to saponify any acetyl derivative which might have formed. The product forms white needles; m. p., 258°. The substance is an indicator, changing from colorless to red at $P_{\rm H}$ 9.1. The alkaline absorption spectrum showed a peak at $\lambda 580 {\rm m}\mu$.

Analyses. Subs., 0.0748: CO₂, 0.1948; H₂O₃, 0.0352. Calc. for $C_{24}H_{22}O_6$: C, 70.93; H, 5.17. Found: C, 71.02; H, 5.22.

3,6-Dimethoxy-2-(2-methoxy-3-methylbenzoyl)benzoic Acid.—This was prepared by methylation of 3,6-dimethoxy-2-(2-hydroxy-3-methylbenzoyl)benzoic acid (I) exactly as described under the preparation of 3,6-dimethoxy-2-(2-methoxy-5-methylbenzoyl)benzoic acid. It was purified from methyl alcohol, forming white needles; m. p., 178°. It was not identical with the benzoyl-benzoic acid obtained by condensing 3,6-dimethoxy-phthalic anhydride with o-cresol methyl ether, which has the constitution 3,6-dimethoxy-2-(4-methoxy-5-methylbenzoyl)benzoic acid.

Analyses. Subs., 0.1438: CO₂, 0.3430; H₂O, 0.0700. Calc. for $C_{18}H_{18}O_6$: C, 65.45; H, 5.45. Found: C, 65.12; H, 5.40.

Subs., 0.4642: required, 0.139 cc. of N NaOH. Calc.: neutr. equiv., 330. Found: 333.

o-Cresol-3,8-dimethoxy-phthalein-dimethyl Ether, (2,2-Bis(4-methoxy-5-methyl-phenyl)3,6-dimethoxyphthalide).—This substance was prepared by refluxing 1 g. of the corresponding phthalein with 5 g. of potassium hydroxide and 4 g. of dimethyl sulfate. The red color disappeared and the ether precipitated from the alkaline solution. It was filtered off and crystallized from acetic acid. It formed white needles; m. p., 202°. This was the same substance as that formed in the condensation of 3,6-dimethoxyphthalic anhydride with o-cresol methyl ether.

Analyses. Subs., 0.0808: CO_2 , 0.2115; H_2O , 0.0433. Calc. for $C_{26}H_{26}O_6$: C, 71.99; H, 5.99. Found: C, 71.37; H, 5.95.

1-Hydroxy-2-methyl-5,8-dimethoxy-anthraquinone (VII).—This was prepared from 3,6-dimethoxy-2-(2-hydroxy-3-methylbenzoyl)benzoic acid, sulfuric acid and boric acid in the same way as was the 1-hydroxy-4-methyl-5,8-dimethoxy-anthraquinone (IX). It was recrystallized from glacial acetic acid, giving red needles; m. p., 165°. Its solution in alkali was red; in concd. sulfuric acid it was blue to blue-red, depending on the concentration.

Analyses. Subs., 0.0360: CO₂, 0.0910; H_2O , 0.0162. Calc. for $C_{17}H_{14}O_5$: C, 68.45; H, 4.69. Found: C, 68.43; H, 5.00.

1,5,8-Trihydroxy-2-methyl-anthraquinone (X).—This was prepared from the ether in the same manner as 1,5,8-trihydroxy-4-methyl-anthraquinone (XII) was prepared from its ether. It was purified from glacial acetic acid, forming red needles that sublimed at 250–60°. It dissolved in alkali with the development of a red, and in coned. sulfuric acid to give a blue-red solution.

Analyses. Subs., 0.1153: CO₂, 0.2821; H₂O, 0.0385. Calc. for C₁₅H₁₀O₅: C, 66.66; H, 3.70. Found: C, 66.74; H, 3.71.

2,5,8-Trihydroxy-1-methyl-anthraquinone (XIII).—A solution of 3 g. of o-cresol-3,6-dimethoxy phthalein (IV) and 1.5 g. of 3,6-dimethoxy-phthalic anhydride in 60 cc. of coned. sulfuric acid was heated for 40 hours in a bath at 125°. The anthraquinone (1 g.) was precipitated by pouring the solution into water and purified by precipitation from alkaline solution by carbon dioxide. It was recrystallized from chloroform, forming dark red needles; m. p., 270°. It was identical with the anthraquinone obtained by condensing 3,6-dimethoxy-phthalic anhydride with o-cresol methyl ether, dehydrating the benzoyl-benzoic acid thus obtained, and demethylating the anthraquinone. The substance dissolved in alkali and in coned. sulfuric acid to give a bluish red solution.

Analyses. Subs., 0.0795: CO₂, 0.1935; H_2O , 0.0255. Calc. for $C_{16}H_{10}O_6$: C, 66.68; H, 3.70. Found: C, 66.38; H, 3.58.

m-Cresol Derivatives. 3,6-Dimethoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic Acid (II).—A mixture of 20 g. of dimethoxy-phthalic anhydride, 40 g. of aluminum chloride, and 120 cc. of m-cresol, after standing for 2 hours, was heated for 12 hours in a bath at 75° with mechanical stirring. The products were worked up as in the analogous p-cresol condensation. The yield of crude benzoyl-benzoic acid was 15 g. (50%), and of phthalein, 17 g.

On recrystallizing the crude benzoyl-benzoic acid from methyl alcohol, two substances were obtained. The least soluble fraction formed white needles that melted at 233° and proved to be the above-mentioned substance.

Analyses. Subs., 0.0933: CO₂, 0.2204; H₂O, 0.0450. Calc. for C₁₇H₁₆O₆: C, 64.59; H, 5.66. Found: C, 64.44; H, 5.35.

Subs., 0.3767: required, 1.19 cc. of N NaOH. Calc.: neutr. equiv., 316. Found: 314.

3-Hydroxy-6-methoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic Acid.—A second, much more soluble substance was obtained from the filtrates in the crystallization of

the crude benzoyl-benzoic acid. This when pure melted at 147° (uncorr.) losing water and resolidifying. A second melting point was reached at about 179°. It was impossible to remove all the water by heating the substance at 120°. At 140° for 48 hours the water was removed completely and the product then melted at 187°. This was analyzed and shown to be a monomethyl ether. It probably has the structure assigned it, but this was not proved.

Analyses. Subs., 0.0557, 0.0860: Co_2 , 0.1307, 0.2005: H_2O , 0.0245, 0.0391. Calc. for $C_{16}H_{14}O_6$: C, 63.57; H, 4.63. Found: C, 63.99, 63.57; H, 4.90, 5.02.

Hydrated subs. (m. p., 147°), 0.1468: CO₂, 0.3275, H₂O, 0.0697. Calc. for C₁₆H₁₄O₆.H₂O: C, 60.00; H, 5.00. Found: C, 60.84; H, 5.27.

Hydrated subs. 0.1673: required, 0.529 cc. of N NaOH. Calc.: neutr. equiv., 320. Found: 316.

3,6-Dimethoxy-2-(2-methoxy-4-methylbenzoyl) benzoic Acid.—This substance was prepared from each of the benzoyl-benzoic acids obtained from m-cresol, by the action of alkali and dimethyl sulfate, in a manner similar to the methylation of the analogous o-and p-cresols. The identity of the trimethyl ethers was proved by a mixed melting point. The product forms white needles from methyl alcohol; m. p., 189°.

Analyses. Subs., 0.0668: CO₂, 0.2078; H_2O , 0.0428. Calc. for $C_{18}H_{18}O_6$: C, 65.45; H, 5.45. Found: C, 65.24; H, 5.48.

Subs., 0.5355: required, 1.61 cc. of N NaOH. Calc.: neutr. equiv., 330. Found: 331.

m-Cresol-3,6-dimethoxy-phthalein; (2,2-Bis(4-hydroxy-6-methylphenyl)3,6-dimethoxy phthalein) (V).—This substance was purified in the same way as was 2,2-bis-(4-hydroxy-5-methylphenyl) 3,6-dimethoxy-phthalein (IV). The product formed white needles; m. p., 271°. It is an indicator, the solution changing from colorless to red at $P_{\rm H}$ 9.8. The alkaline absorption spectrum showed a peak at $\lambda 585 {\rm m} \mu$.

Analyses. Subs., 0.0708: CO₂, 0.1843; H₂O, 0.0338. Calc. for C₂₄H₂₂O₆: C, 70.93; H, 5.17. Found: C, 71.10; H, 5.30.

1-Hydroxy-3-methyl-5,8-dimethoxy-anthraquinone (VIII).—A solution of 5 g. of 3,6-dimethoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic acid (II) and 5 g. of boric acid in 100 cc. of 7% oleum was heated for one hour on the steam-bath. The solution was poured over ice and extracted with chloroform. The chloroform solution was washed with sodium bicarbonate solution and again with alkali, which removed the anthraquinone. Acidification precipitated the substance. It was purified from glacial acetic acid, forming red needles; m. p., 172°; yield, about 0.25 g. (6%). Not enough of the substance was obtained to analyze, but it was converted to the corresponding trihydroxy compound (XI).

1,5,8-Trihydroxy-3-methyl-anthraquinone (XI).—The corresponding dimethyl ether (VIII) was refluxed with glacial acetic and hydrobromic acids for 5 hours. As the mixture cooled the trihydroxy compound separated. It was purified from glacial acetic acid, forming red needles; m. p., 227°. The substance dissolved in alkali, giving a blue solution, while the dimethyl ether gave a red solution. Both gave blue-red solutions in concd. sulfuric acid.

Preparation of 3,5-Dimethoxy Phthalic Anhydride. The Acid Barium Salt of 3,5-Disulfo-benzoic Acid.—This substance was prepared by a slight modification of the method of Barth²⁵ and Hohenemser.²⁶ A mixture of 900 g. of benzoic acid, 300 g. of phosphorus pentoxide, and 1500 cc. of 50% oleum was sealed in an iron bomb and heated in an electric furnace for 5 hours at 240-250°. After it had cooled, the bomb was

²⁵ Barth, Ann., 159, 222 (1871).

²⁶ Hohenemser, Ber., 35, 2305 (1902).

3,5-Dimethoxy-2-(4-methoxy-2-methylbenzoyl)benzoic Acid (XVI).—By condensing m-cresol methyl ether with 3,5-dimethoxy-phthalic anhydride, this substance was obtained in 40% yield. It was recrystallized from dil. methyl alcohol, forming white needles; m. p., 233°.

A mixed-melting-point determination showed that this acid is different from the isomer (m. p., 219°) obtained by methylating the compound (XV), indicating that the rule of condensation *ortho* to hydroxyl and *para* to methoxyl groups holds for 3,5- as well as 3,6-dimethoxy phthalic anhydrides.

3,5-Dimethoxy-*m*-cresol-phthalein (2,2-Bis - (4 - hydroxy-6 - methylphenyl)3,5 - dimethoxy Phthalide.—It was found impossible to crystallize this compound free from tarry impurities by the methods used successfully with the other phthaleins.

Attempts at Preparation of Emodin Dimethyl Ether.—A solution of 5 g. of 3,5-dimethoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic acid (XV) and 5 g. of boric acid in 50 cc. of 7% oleum was warmed on the steam-cone for an hour. The anthraquinone was purified as described under the preparation of 1-hydroxy-3-methyl-5,8-dihydroxy-anthraquinone. A very small amount was obtained, sulfonation apparently taking place to a considerable extent. The product crystallized from dil. alcohol in yellow needles; m. p., about 185°. Its solution in alkali was red. This product was refluxed with excess of dimethyl sulfate and alkali for 2 hours. The trimethoxy compound was extracted from the alkaline solution with ether. On evaporation of the ether it was obtained in yellow needles; m. p., about 175–180°. Not enough was obtained to purify. It dissolved in coned. sulfuric acid with the development of a red color. This crude trimethyl ether was used for the absorption spectrum determinations.

Nitration of 3,5-Dimethoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic Acid (XV). 3,5-Dimethoxy-2-(2-hydroxy-4-methyl-5-nitrobenzoyl)benzoic Acid (XIX).—A solution of 4 g. of the benzoyl-benzoic acid in 80 cc. of glacial acetic acid was treated with 1 cc. of nitric acid (sp. gr. 1.42) in 20 cc. of glacial acetic acid at 50-60° for 3 hours. On adding water the nitro acid was obtained in quantitative yield. It was recrystallized from alcohol in light yellow needles; m. p., 241°.

Analyses. Subs., 0.0823: CO₂, 0.1697; H₂O, 0.0325. Calc. for C₁₇H₁₅O₈N: C, 56.51; H, 4.15. Found: C, 56.23; H, 4.38.

Subs., 0.1195: required, 0.642 cc. of N NaOH. Calc.: neutr. equiv., 361, or 180 if the OH were neutralized. Found: 186.

Condensation of 3,5-Dimethoxy-phthalic Anhydride with o-Nitro-m-cresol. 3,5-Dimethoxy-2-(4-hydroxy-2-methyl-5-nitrobenzoyl)benzoic Acid (XVIII).—A mixture of 10 g. of 3,5-dimethoxy-phthalic anhydride, 35 g. of o-nitro-m-cresol, 31 and 20 g. of aluminum chloride was heated and stirred in a bath at 75° for 20 hours. The excess of nitrocresol was steam distilled and the product worked up as before; yield of acid, 9 g. (62%). It was purified from methyl alcohol, forming white needles; m. p., 181°. Only a trace of phthalein derivative was obtained.

Analyses. Subs., 0.1098: CO₂, 0.2299; H₂O, 0.0446. Calc. for C₁₇H₁₅O₈N: C, 56.51; H, 4.15. Found: C, 57.00; H, 4.51.

Subs., 0.1143: required, 0.620 cc. of N NaOH. Calc.: neutr. equiv., 361; or 180 if the OH were neutralized. Found: 184.

Summary

1. A satisfactory method has been developed for the condensation of phthalic anhydride containing methoxyl groups with cresols to form substituted benzoyl-benzoic acids.

³¹ Keller, Ann., 259, 223 (1890).

- 2. 3,6-Dimethoxy-phthalic anhydride was condensed with o-, m- and p-cresols.
- 3. The benzoyl-benzoic acids thus formed were condensed by means of sulfuric acid to the corresponding trihydroxy-methyl-anthraquinones or their ethers.
- 4. The exact structures of the benzoyl-benzoic acid derivatives and of the anthraquinones have been established: first, by comparison with the isomeric bstances (described in the following paper) prepared by condensing 3,6-dimethoxy-phthalic anhydride with cresol ethers; and second, by comparison with the trihydroxy-methyl-anthraquinone of known structure prepared from 3,6-dimethoxy-o-cresolphthalein.
- 5. It has been established that the entering group takes the *ortho* position to the hydroxyl in the cresols.
- 6. The anthraquinones from the benzoyl-benzoic acids derived from o-and p-cresol form readily, and those from the m-cresol only with great difficulty.
- 7. A preliminary study of the condensation of 3.5-dimethoxy-phthalic anhydride with m-cresol and of the formation of the anthraquinone from the resulting benzoyl-benzoic acid derivative has been made, with the object of the synthesis and proof of the structure of the natural drug emodin.
- 8. The course of the condensation of the 3,5-dimethoxy-phthalic anhydride with *m*-cresol was determined by a comparison of the products obtained with this cresol and with *m*-cresol methyl ether and *o*-nitro-*m*-cresol.
- 9. The absorption spectra of the anthraquinones and phthaleins were obtained.

TRIHYDROXY-METHYL-ANTHRAQUINONES.

By J. H. GARDNER¹ WITH ROGER ADAMS RECEIVED JULY 23, 1923

In the previous paper² a satisfactory method was developed for the condensation of certain phthalic anhydrides containing methoxyl groups with cresols. The resulting benzoyl-benzoic acids were converted to substituted anthraquinones. A detailed study of the condensation of 3,6-dimethoxy-phthalic anhydride with cresols showed that the reactions took place very readily by means of anhydrous aluminum chloride and an excess of cresol as a solvent with the formation of products in which the ketonic carbonyl of the benzoyl-benzoic acid was *ortho* to the hydroxyl group of the cresol. Sulfuric acid in the presence of a little boric acid

¹ This communication is an abstract of a thesis submitted by J. H. Gardner in partial fulfilment of the requirements for the Degree of Doctor of Philosophy in Chemistry at the University of Illinois.

² Graves and Adams, This Journal, 45, 2439 (1923).

converted the benzoyl-benzoic acids thus formed into the corresponding anthraquinones and these were demethylated to the trihydroxy-methylanthraquinones by means of hydrobromic acid. The benzoyl-benzoic acids were accompanied by diphenyl-phthalide derivatives in the formation of which the condensation took place in the para position to the hydroxyl group of the o- and m-cresol residues and in the ortho position to the hydroxyl group of the p-cresol residue.

In the present work the condensation of 3,6-dimethoxy-phthalic anhydride with the methyl ethers of o-, m- and p-cresol has been studied. The conversion to the corresponding anthraquinone derivatives has been carried out and the structure of the intermediate and final products has been determined.

The initial condensation to the benzoyl-benzoic acids was effected by means of anhydrous aluminum chloride, using an excess of the cresol ether as a solvent. The benzoyl-benzoic acids from o-, m- and p-cresol methyl ethers (I, II and III) were obtained in yields of 24%, 65% and 48%, respectively, as the average of several runs.

In the case of the m-cresol methyl ether, more vigorous conditions were used in the condensation than in the others, thus causing the hydrolysis of one of the ether groups (II).

The acids just mentioned from the o- and p-cresol methyl ethers were accompanied by alkali-insoluble diphenyl-phthalide derivatives (IV and V) in yields of 76% and 21%, respectively. No product of this type formed in the condensation with m-cresol methyl ether, possibly on account of the vigorous conditions used.

The conversion of the benzoyl-benzoic acids into anthraquinone derivatives was first accomplished with the acids from o- and p-cresol methyl ethers (I and III) by heating with concd. sulfuric acid to 150° and cooling immediately with ice. The anthraquinone derivatives thus produced were partially demethylated during their formation.

The benzoyl-benzoic acids were also converted to anthraquinones by heating with concd. sulfuric acid for 20 to 30 minutes at 145–155°. Under these conditions the products were formed and completely demethylated (VI and VIII); this method is, therefore, to be preferred to the other, as a single product is thus obtained.

Such a very small amount of anthraquinone derivative from the acid obtained from *m*-cresol methyl ether resulted from either of the above treatments, that it could not be purified. This is in accord with the results of Weizmann³ and of Graves and Adams² who had difficulty in forming anthraquinones from substituted benzoyl benzoic acids of a similar type.

The structures of the benzoyl-benzoic acids as given (I, II and III) were shown to be correct. Such structures would be expected after a consideration of the work of Nourisson⁴ and Weizmann^{3b} who showed that condensation of phthalic anhydride with phenol ethers took place para to the methoxyl group, providing that position was open. In the first place, the benzoyl-benzoic acids from o- and m-cresol methyl ethers were different from those obtained by the methylation of the benzoylbenzoic acids from 3,6-dimethoxy-phthalic anhydride and o- and m-cresols. The benzoyl-benzoic acid from p-cresol methyl ether was the same as that obtained by the methylation of the condensation product from 3,6-dimethoxy-phthalic anhydride and p-cresol.

Second, the identity of the completely demethylated anthraquinone derivative (VI) from 3,6-dimethoxy-phthalic anhydride and o-cresol methyl ether with that obtained by the condensation of o-cresol-3,6-dimethoxy-phthalein dimethyl ether with 3,6-dimethoxy-phthalic anhydride and sulfuric acid, also shows without question the constitution of the original substance.

³ Weizmann, J. Chem. Soc., (a) 97, 687 (1910); (b) 91, 1626 (1907).

⁴ Nourisson, Ber., 19, 2103 (1886).

Still further proof, and more direct, for the structure of the o-cresol methyl ether compound (I) was obtained. The demethylated anthraquinone (VI) from 3,6-dimethoxy-phthalic anhydride and o-cresol methyl ether was distilled with zinc dust in order to obtain the corresponding methyl anthracene. This, in turn, was oxidized to the methyl anthraquinone and identified as the α -methyl compound. This proves conclusively that the initial condensation must have been para to the methoxyl group in the cresol ether, since if it had been ortho, β -methyl-anthracene would have resulted.

By analogy, it is fair to assume that the *m*-cresol methyl ether also condensed in an analogous way, the ketonic carbonyl going *para* to the methoxyl group. It was mentioned above that the acid was partially demethylated during its formation and it is most probable, judging from the work of Kostanecki and Dreher, that the methoxyl group *ortho* to the ketone carbonyl (II) is the one which has been split.

The constitution of the benzoyl-benzoic acid from p-cresol methyl ether is most certainly that given by Formula III. It is identical with the acid obtained by the methylation of the condensation product of 3,6-dimethoxy-phthalic anhydride and p-cresol.

With the constitution of the benzoyl-benzoic acids fixed, the structures of the anthraquinones formed from them can easily be proved. In the case of the p-cresol methyl ether derivative, only one anthraquinone formula is possible (VIII). The anthraquinone from the o-cresol methyl ether derivative might have one of two formulas (VI or VII), depending upon whether water was eliminated using the hydrogen atom o-rho or p-ara to the methyl group. It has already been mentioned, however, under the discussion of the structure of the benzoyl-benzoic acids, that α -methyl-anthracene could be obtained by reduction of this anthraquinone, thus showing that the hydrogen o-rho to the methyl group has been eliminated and that Formula VI is correct.

It was mentioned that during the formation of the anthraquinones from the benzoyl-benzoic acids under certain conditions partial demethylation took place. From the benzoyl-benzoic acid obtained from o-cresol methyl ether, a monomethylated anthraquinone was formed. The exact structure was not determined, but it seems probable that the product was 2-methoxyl-methyl-5,8-dihydroxy-anthraquinone. The benzoyl-benzoic acid from p-cresol methyl ether yielded an anthraquinone dimethyl ether which was identical with that obtained by Graves and Adams from 3,6-dimethoxy-phthalic anhydride and p-cresol, and so must be 4-hydroxy-1-methyl-5,8-dimethoxy-anthraquinone. This is in accord with the observations of Oesterle who showed that one of the two methoxyl groups in the 1,8-positions in chrysazin is more reactive than the other.

⁵ Kostanecki and Dreher, Ber., 26, 78 (1893).

⁶ Oesterle, Arch. Pharm., 253, 335 (1915).

The structures of the phthalein by-products (IV and V) are correct without doubt. The one formed from the o-cresol methyl ether was the same as that obtained by the methylation of the phthalein obtained by the condensation of 3,6-dimethoxy-phthalic anhydride with o-cresol. In the case of the condensation of the 3,6-dimethoxy-phthalic anhydride with the p-cresol, a fluoran was produced due to the dehydration of the phthalein first formed. When the p-cresol methyl ether was used, no such fluoran formation was possible and the corresponding phthalein was, therefore, produced.

Experimental Part

The 3,6-dimethoxy-phthalic anhydride was prepared as described in the previous paper. The cresol ethers were made by the usual method of treatment of the cresols with sodium hydroxide and dimethyl sulfate.

Condensation of 3,6-Dimethoxy-phthalic Anhydride with the Cresol Methyl Ethers

p-Cresol Methyl Ether Derivatives.⁷ 3,6-Dimethoxy-2-(2-methoxy-5-methylbenzoyl) benzoic Acid (III).—A mixture of 5 g. of 3,6-dimethoxy-phthalic anhydride and 25 cc. of p-cresol methyl ether was prepared in a large Pyrex test-tube provided with a mechanical stirrer. To this was added 15 g. of anhydrous aluminum chloride, and the mixture was stirred continuously for 1 hour so as to give a homogeneous reaction mixture; during this time evolution of hydrogen chloride took place. The tube was then heated for 6 hours at 70°; after 4 to 5 hours the mixture became so thick that it could no longer be stirred.

At the end of the heating the mixture was cooled and slowly treated with 50 cc. of 1:1 hydrochloric acid. The excess of cresol ether was removed by steam distillation, as well as any free cresol which might have formed during the reaction. The residual mixture in the flask was cooled and the dark brown solid was filtered. It was boiled with 10% sodium hydroxide, cooled and filtered. The residue was set aside and the alkaline solution was saturated with carbon dioxide. This caused the precipitation of aluminum hydroxide which was filtered off. From this filtrate $3.5~{\rm g}.~(44\%)$ of 3.6-dimethoxy-2-(2-methoxy-5-methylbenzoyl)benzoic acid was obtained by acidification with hydrochloric acid. It was purified by recrystallization from methyl alcohol and washing with ether, forming colorless, truncated prisms melting at $203-204^{\circ}$.

Analyses. Subs., 0.0812: CO₂, 0.1942; H_2O , 0.0866. Calc. for $C_{15}H_{18}O_6$: C, 65.45; H, 5.45. Found: C, 65.23; H, 5.01.

p-Cresol-3,6-dimethoxy-phthalein Dimethyl Ether, or 2,2-Bis(2-methoxy-5-methyl-phenyl)-3,6-dimethoxyphthalide⁸ (V).—In the preparation of 3,6-dimethoxy-2-(2 methoxy-5-methylbenzoyl)benzoic acid (III) there was always obtained as a by-product a portion insoluble in sodium hydroxide solution. From the reaction mixture described, there was obtained 2.2 g. (21%) of this insoluble material. It was purified by recrystallization from glacial acetic acid, forming colorless needles melting at 187.5°. It was dried to constant weight at 100° before analysis.

Analyses. Subs., 0.0826: CO₂, 0.2164; H₂O, 0.0426. Calc. for $C_{25}H_{26}O_6$: C, 71.89; H, 5.99. Found: C, 71.45; H, 5.73.

⁷ All melting points given in this paper are corrected.

⁸ Nomenclature according to the system used in Chemical Abstracts.

1,5,8-Trihydroxy-4-methyl-anthraquinone.—A mixture of 5 g. of 3,6-dimethoxy-2-(2-methoxy-5-methylbenzoyl)benzoic acid (III) and 100 cc. of concd. sulfuric acid was heated rapidly to 150°. When this temperature was reached the mixture was poured over ice and the dark red precipitate which formed was filtered out. It was dissolved in 10% aqueous sodium hydroxide, the solution filtered and the mixture of anthraquinone derivatives precipitated by means of carbon dioxide; yield, 2.7 g., or 60%. By recrystallization of this crude material from acetone, two fractions were obtained in about equal amounts. The less soluble of these, which proved to be the 4,5,8-trihydroxy-1-methyl-anthraquinone, was recrystallized from glacial acetic acid for further purification. It formed fine red needles, melting at 276–278° with sublimation. It is soluble in concd. sulfuric acid with a blue-violet color, and in alkalies with a violet-red color.

Analyses. Subs., 0.0734: CO_2 , 0.1784; H_2O , 0.0250. Calc. for $C_{15}H_{10}O_5$: C, 66.67; H, 3.70. Found: C, 66.29; H, 3.78.

The more soluble compound obtained from the acetone crystallization proved to be the 1-hydroxy-4-methyl-5,8-dimethoxy-anthraquinone. It was purified further by recrystallization from glacial acetic acid from which it formed long, red needles with a yellowish, metallic gleam. It melted at 224° when pure, dissolved in concd. sulfuric acid with the development of a blue-violet color and in sodium hydroxide to give a bluish-red solution.

Analyses. Subs., 0.0620: CO₂, 0.1566; H₂O, 0.0247. Calc. for C₁₇H₁₄O₅: C, 68.46; H, 4.70. Found: C, 68.89; H, 4.47.

As stated in the introduction, a mixture of products consisting of partially methylated and entirely demethylated anthraquinones by the condensation of 3,6-dimethoxy-2-(2-methoxy-5-methylbenzoyl)benzoic acid (III) and sulfuric acid, could be avoided if the conditions used for the condensation were slightly modified. This latter procedure is to be preferred.

A mixture of $8.5\,\mathrm{g}$. of the benzoyl-benzoic acid and $85\,\mathrm{cc}$. of concd. sulfuric acid was heated at $145-155^\circ$ for 20 minutes. The solution was then poured onto ice, and the precipitate filtered out and redissolved in 10% sodium hydroxide solution. The alkaline solution thus obtained was saturated with carbon dioxide, causing the precipitation of $4.5\,\mathrm{g}$. (65%) of practically pure 4.5.8-trihydroxy-1-methyl-anthraquinone. This was further purified from glacial acetic acid as described above.

o-Cresol Methyl Ether Derivatives. 3,6-Dimethoxy-2-(4-methoxy-5-methylben-zoyl) benzoic acid (I).—A mixture of 5 g. of 3,6-dimethoxy-phthalic anhydride and 20 cc. of o-cresol methyl ether was placed in a large Pyrex test-tube provided with a mechanical stirrer. To this was added 8 g. of anhydrous aluminum chloride and after the mixture had been stirred for an hour it was heated to 65° during a period of 2 hours and continuously stirred, after which it was held at that temperature for 5 hours.

The mixture was cooled and decomposed with 50 cc. of 1:1 hydrochloric acid. The resulting product was treated in exactly the same way as described under the corresponding p-cresol methyl ether derivative. There was thus obtained 1.9 g. (26%) of 3,6-dimethoxy-2-(4-methoxy-5-methylbenzoyl)benzoic acid. It was purified by crystallization from methyl alcohol, then from acetone, and finally dried to constant weight. It was a white powder, melting at 192°.

Analyses. Subs., 0.0934: CO₂, 0.2266; H₂O, 0.0442. Calc. for C₁₈H₁₈O₆: C, 65.45; H, 5.45. Found: C, 66.17; H, 5.26.

o-Cresol-3,6-dimethoxy-phthalein Dimethyl Ether, 2,2-Bis(4-methoxy-5-methyl-phenyl)3,6-dimethoxy-phthalide (IV).—From the condensation just described 8 g. (76%) of the material insoluble in sodium hydroxide was obtained. This was purified by recrystallization from glacial acetic acid, forming colorless needles; m. p., 202-203°.

Analyses. Subs., 0.0808: CO₂, 0.2115; H_2O , 0.0433. Calc. for $C_{26}H_{26}O_6$: C, 71.89; H, 5.99. Found: C, 71.37; H, 5.95.

2-Methoxy-1-methyl-5,8-dihydroxy-anthraquinone.—A mixture of 5 g. of 3,6-dimethoxy-2-(4-methoxy-5-methylbenzoyl)benzoic acid (I) and 100 cc. of concd. sulfuric acid was heated rapidly to 150° and then poured onto ice. The red precipitate was purified as described under the corresponding p-cresol methyl ether derivatives. There was thus obtained 2.5 g. (58% yield) of anthraquinone.

The crude material was recrystallized from glacial acetic acid, forming dark red needles melting at 249–249.5°. From the mother liquors small amounts of 2,5,8-tri-hydroxy-1-methyl-anthraquinone were obtained. The monomethyl ether is soluble in concd. sulfuric acid with the formation of a blue-violet color and dissolved in alkalies to give a blue-red solution.

Analyses. Subs., 0.0823: CO₂, 0.2025; H₂O, 0.0320. Calc. for C₁₆H₁₂O₅: C, 67.61; H, 4.23. Found: C, 67.11; H, 4.32.

2,5,8-Trihydroxy-1-methyl-anthraquinone (VI).—This substance was obtained in small amounts from the mother liquor from the previous condensation, but it was more readily obtained in a pure state by the following procedure.

A mixture of 4 g. of 3,6-dimethoxy-2-(4-methoxy-5-methylbenzoyl)benzoic acid (I), 3 g. of boric acid and 40 cc. of concd. sulfuric acid was heated at 150° for 30 minutes. The solution was poured onto ice, the liquid filtered and the precipitate dissolved in 10% sodium hydroxide solution. After filtration the solution was saturated with carbon dioxide, thus precipitating 1.5 g. (45%) of 2.5.8-trihydroxy-1-methyl-anthraquinone. It was purified by recrystallization from dil. acetic acid and then from chloroform. It formed dark red needles, melting at 270° .

Analyses. Subs., 0.0795: CO₂, 0.1936; H₂O, 0.0255. Calc. for $C_{15}H_{10}O_5$: C, 66.67; H, 3.70. Found: C, 66.38; H, 3.56.

This same substance was obtained by the condensation of 2,2-bis(4-methoxy-5-methylphenyl)-3,6-dimethoxy-phthalide (IV) with 3,6-dimethoxy-phthalic anhydride and sulfuric acid. A mixture of 7 g. of the phthalide with 185 cc. of concd. sulfuric acid and 3.5 g. of 3,6-dimethoxy-phthalic anhydride was heated for 2 days at 125°. The solution was poured onto ice, the dark red precipitate filtered and dissolved in 10% sodium hydroxide solution. By saturating this solution with carbon dioxide, 7.5 g. of the anthraquinone derivative was obtained.

Since the phthalide was formed in large amounts by the condensation of 3,6-dimethoxy-phthalic anhydride with o-cresol methyl ether, this method of preparation of the 2,5,8-trihydroxy-1-methyl-anthraquinone was more satisfactory than that by the dehydration of 3,6-dimethoxy-2-(4-methoxy-2-methylbenozyl)benzoic acid (I).

Conversion of 2,5,8-trihydroxy-1-methyl-anthraquinone (VI) to 1-methyl-anthraquinone.—A sample of 2,5,8-trihydroxy-1-methyl-anthraquinone was reduced to methyl-anthracene by distillation with zinc dust, following the method of Gattermann. The crude material thus obtained was oxidized to methyl-anthraquinone, following the method of Fischer and Reinkober. The product thus obtained was purified by crystallization from dil. acetic acid, forming yellow needles melting at 167°, which is the melting point of 1-methyl-anthraquinone. When this product was mixed with a sample of pure 2-methyl-anthraquinone melting at 174°, the melting point of the mixture was lowered to 154°, indicating that the compounds were not the same.

m-Cresol Methyl Ether Derivatives. 3-Hydroxy-6-methoxy-2-(4-methoxy-1-

⁹ Gattermann, "Practical Methods of Organic Chemistry," MacMillan and Co., 1914, p. 369.

¹⁰ Fischer and Reinkober, J. prakt. Chem., [2] 92, 49 (1915).

methylbenzoyl)benzoic acid (II).—A mixture of 5 g. of 3,6-dimethoxy-phthalic anhydride and 25 cc. of m-cresol methyl ether was condensed in the same manner as the o-and p-cresol methyl ethers with the exception of a few details. The mixture was heated up to 75° during the course of 1.5 hours, and maintained at that temperature for 7 hours. When worked up in the manner previously described, no alkali-insoluble product was obtained but merely 4.9 g. (65%) of a dimethyl ether, probably 3-hydroxy-6-methoxy-2-(4-methoxy-1-methylbenzoyl)benzoic acid (II). This was purified by crystallization from methyl alcohol, forming colorless prisms melting at 194–195°. It was dried to constant weight before it was analyzed.

Analyses. Subs., 0.0766: CO_2 , 0.1806; H_2O , 0.0342. Calc. for $C_{17}H_{16}O_6$: C, 64.56; H, 5.06. Found: C, 64.30; H, 4.67.

Summary

- 1. 3,6-Dimethoxy-phthalic anhydride was condensed with o-, m- and p-cresol methyl ethers.
- 2. The benzoyl-benzoic acids formed from the o- and p-cresol methyl ethers were condensed by means of sulfuric acid to the corresponding trihydroxy-methyl-anthraquinones or their methyl ethers. By varying the conditions of condensation it was possible either to obtain partial demethylation or complete demethylation during this reaction.
- 3. The structures of the benzoyl-benzoic acids obtained were established: first, by comparison with the isomeric substances obtained by the condensation of 3,6-dimethoxy-phthalic anhydride with cresols; and second, by direct proof.
- 4. It has been established that the entering group takes the para position to the methoxyl groups in the o- and m-cresol ethers and the ortho position to the methoxyl in the p-cresol methyl ether.
- 5. The structure of the anthraquinones obtained from the benzoylbenzoic acids was determined.

THE YIELDS OF SOME GRIGNARD REAGENTS

By Henry Gilman and Roy McCracken¹ Received July 31, 1923

Introduction

In connection with a series of studies involving the Grignard reagent, it was necessary to determine the approximate yield in the preparation of a number of typical RMgX compounds. A knowledge of such yields is quite indispensable in certain studies. In particular is this true of reactions involving an excess of some compound treated with the Grignard reagent, and when the interpretation of mechanism of such a reaction

¹ This paper is an abstract of a thesis presented by Roy McCracken in partial fulfilment of the requirements for the degree of Master of Science in Chemistry at Iowa State College.

is in no small way determined by the yields of products. Apart from these immediate considerations, the study is not without some interest in such general problems as steric hindrance and the order of activity of halogens in organic compounds.

The method used for the quantitative estimation of the various compounds was that previously described.² Although no optimum condition was determined for the formation of any of the reagents described in this paper, advantage was taken of the opportunity to incorporate where possible those factors which were found earlier³ to give a maximum yield of ethylmagnesium iodide. It is quite probable that although the quantity of organic halide used was only that which would react theoretically with 1.15 g. of magnesium, the yields determined are such as may be expected, in larger runs made under comparable conditions. In this connection a quantitative study of yields, when the commonly used solvent (ether) is replaced in large part by other more desirable solvents such as benzene, is in progress. Here the method of analysis by titration will be checked in part by the preparation of standard compounds in fairly large quantities.

Procedure

The technique was essentially identical with that previously described in determining the best conditions for the preparation of ethylmagnesium iodide.³ In each run 1.25 g. of magnesium turnings was used, and the weight of halide taken was approximately that which would theoretically react with 1.15 g. of magnesium. A small crystal of iodine was added in each run as a catalyst; the halide in ether was added over a 45-minute period, and stirring was used throughout.

With a few of the compounds (the bromotoluenes, β -bromostyrene, and α -bromonaphthalene) which react with magnesium rather sluggishly at first, a minor alteration in procedure was made. Instead of adding 25 cc. of ether to the magnesium before the addition of the halide, only about 3 cc. was run in and then about 2 cc. of the ether solution of halide. This mixture was warmed until the reaction set in, and then the remainder of the ether solution of halide was added over 45 minutes.

Duplicate runs were made on each compound, and from each run two samples were removed for analysis. The yields given in the following table are, therefore, average yields for at least 4 analyses. Because of the apparently unusual results observed with some of the compounds, repeated check determinations were made up to 12 and 16 analyses. The agreement in results was of the order already noted: 3 very few of the analyses varied from the average by more than 1%, and practically all were within 0.5% of the average.

³ Gilman and Meyers, ibid., 45, 159 (1923).

TABLE I RESULTS

Halide used	Av. % yield of corres. organomagn hal.		Av. % yield of corres. organomagn, hal.		Av. % yiel of corres. organomage hal.	
n-Propyl iodide.	. 79.35	n-Butyl bromide.	91.23	$o ext{-Bromotoluene}$	86.6	5
n-Butyl iodide	. 65.23	iso-Butyl bromid	e 78.23	m-Bromotoluene	84.7	5
n-Amyl iodide	. 75.76	sec-Butyl bromid	e 68.26	p-Bromotoluene	88.1	6
n-Hexyl iodide	. 59.50	tert-Butyl bromid	e 20.62	Benzyl chloride	94.2	8
n-Heptyl iodide.	. 64.27	n-Butyl chloride.	87.38	α-Bromonaphthale	ne. 70.5	0
n-Octyl iodide	. 44.22	Bromobenzene	94.37	Bromocyclohexane	68.3	2
Lauryl bromide.	. 73.70	Iodobenzene	84.58	β -Bromostyrene	47.5	9

With n-butyl iodide a first pair of duplicate runs gave an average percentage yield of 78.24. Because it was felt early in the work that the yield should have been nearer to those with n-butyl bromide and n-butyl chloride, a check determination was made on a more highly purified sample. This second pair of duplicate runs averaged more than 10% lower. This necessitated another determination, and to avoid any uncertainty a third and a fourth pair of duplicate runs were made. The second, third and fourth runs agreed quite closely and the average of these three runs (12 analyses) is that given, 65.23%. Although the percentage obtained in the first determination fits in admirably with the drop in yield with increasing length of carbon chain, it should be discarded.

In the cases of n-hexyl iodide, lauryl bromide and bromocyclohexane a pair of duplicate runs was made and the result for each is the average of 8 analyses.

n-Butyl chloride showed no evidence of a reaction with magnesium until after three hours of stirring. In sequence, each reaction mixture was stirred for 4 hours, then allowed to stand for 8 hours, and finally stirred for 4 hours.

The percentage listed for benzyl chloride is an average of a pair of duplicate runs. In another determination, where the benzyl chloride was used directly without special purification by drying and by distillation, the yield was 4% less.

All halides were purified at least by a combination of drying and distillation, with the exception of the butyl bromides, butyl chloride, and the bromotoluenes. These were used directly from small stock bottles, and were of the regular high grade quality to be had from American houses.

Discussion

The yields of organomagnesium halides prepared from normal alkyl iodides confirm in large part several observations to be found in the literature. It has long been known that the yield of Grignard reagent drops with the increasing length of the carbon chain, and that probably the concurrent Wurtz reaction becomes more prominent.

Two interruptions to an orderly decrease, however, are to be noted with *n*-butyl and *n*-hexyl iodides. Several check analyses with highly and freshly purified samples failed to alter appreciably the average percentages indicated. If an explanation for this apparent irregularity is sought in the phenomenon of alternating properties of even and odd numbered members of an homologous series, it must be remembered that the yield of ethylmagnesium iodide, determined scores of times, has always been considerably higher than that of *n*-propylmagnesium iodide.

The yields of the 4 butylmagnesium bromides indicate in a striking

fashion that the increasing complexity of branching of an alkyl group runs parallel with a decrease in yield of the corresponding organomagnesium halides.

The three bromotoluenes show comparatively small differences.

A comparison of yields of several of the compounds reveals the desirability of using bromides instead of iodides where the bromides are not too volatile and where there is not too much difficulty in initiating a reaction with magnesium. First, n-butyl bromide gives a decidedly larger yield of the corresponding organomagnesium compound than does n-butyl iodide. Second, the yield of phenylmagnesium bromide is significantly larger than that of phenylmagnesium iodide. Third, it is quite obvious that if the regular decrease in yield with normal alkyl halides extends to the higher members of a series, the yield of laurylmagnesium bromide far exceeds what one might expect for laurylmagnesium iodide.

In this connection the yield of n-butylmagnesium chloride is noteworthy. It is considerably larger than that of n-butylmagnesium iodide and only slightly smaller than that of the corresponding bromide. There is a possibility that it might exceed the yield of bromide if the reaction with magnesium could be made to start more easily. This point is to be tested in connection with some studies on the activation of reagents used in the preparation of organomagnesium compounds. There is undoubtedly a limiting factor here when one compares the halogen attached to like radicals, because work recently published and studies now being carried on in this Laboratory point strongly to decidedly poor yields of organomagnesium fluorides, whenever it is possible to prepare them at all.

The yield of benzylmagnesium chloride is surprisingly high. For this reason it was checked and re-checked. The literature contains many references to the rather large quantity of dibenzyl formed by the usual Wurtz-Fittig reaction which apparently accompanies all preparations of the Grignard reagent. It is highly probable, therefore, that the conditions for an optimum yield of ethylmagnesium iodide which have been extended to the compounds mentioned in this study might, for the present, be advantageously used in the preparation of all Grignard reagents.

The yields of the last three compounds listed were determined because they are typical of some classes of substances frequently used in synthetic work.

Summary

The yields of a number of typical Grignard reagents have been determined, and attention has been directed to some apparent regular-

⁴ The observations on chlorides should be restricted to alkyl chlorides, for although it is possible to prepare phenylmagnesium chloride directly the reaction is unusually sluggish and the yield such as to make the preparation essentially without value.

THE FORMATION OF FREE RADICALS BY REDUCTION WITH
VANADOUS CHLORIDE

Preliminary Paper

By J. B. Conant and A. W. Sloan Received August 3, 1923

The addition of vanadous chloride to a solution of triphenylpyrylium chloride (I) causes the formation of a reddish precipitate which can be obtained in a fairly pure condition by filtering in an atmosphere of carbon dioxide. This colored, insoluble substance behaves like a free radical; a chloroform solution of it is bright red and the color disappears when the solution is shaken with air. The substance is reoxidized to the pyrylium salt by ferric chloride; if this process is carried out quantitatively in the absence of oxygen a maximum of one molecule of ferric chloride is required. Considerably less than this amount suffices to oxidize a precipitate which has stood for some hours even in an atmosphere of carbon dioxide; the compound is apparently unstable.

While these facts clearly indicated that we were dealing with a free radical, we desired to obtain still more positive evidence. We, therefore, investigated the reduction of the salts of phenylxanthenol (II) from the chloride of which Gomberg¹ obtained the free radical phenylxanthyl by the action of metals in benzene solution. Phenylxanthenol dissolves to a slight extent in coned. hydrochloric acid, producing an orange-colored solution. This solution presumably contains a chloride for which the oxonium formula (III) can be written. This salt is much more readily hydrolyzed than the pyrylium salt, so that it is necessary to work with coned. hydrochloric acid solutions. When such a solution of phenyl-xanthylium chloride is treated with vanadous chloride a brown precipitate

$$\begin{array}{c|c} C - C_{e}H_{5} \\ \hline C + CH \\ C \\ C_{b}H_{5} - C \\ \hline C \\ C - C_{e}H_{5} \\ \hline C \\ CI \\ \hline (I) \\ \hline \begin{pmatrix} C_{e}H_{4} \\ C_{e}H_{4} \\ C \\ C_{e}H_{4} \\ C \\ C_{e}H_{5} \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C \\ C_{e}H_{5} \\ C_{e}H_{5} \\ C \\ C_{e}H_$$

¹ Gomberg and Cone, Ann., 370, 154 (1909).

is formed which is very similar in its reactions to the substance formed by the reduction of triphenylpyrylium chloride. It dissolves in chloroform or benzene giving a red solution which to the eye seems identical with solutions of phenylxanthyl (IV) prepared according to Gomberg's procedure. Furthermore, on shaking these solutions with air a peroxide is formed identical with the peroxide formed by oxidation of phenylxanthyl. There is, therefore, no doubt that vanadous chloride reduces phenylxanthylium chloride to phenylxanthyl, and there is every reason to believe that from triphenylpyrylium chloride a corresponding free radical is formed.

This novel type of reduction is not confined to oxonium salts. The so-called carbonium salts of triphenylcarbinol are reduced by vanadous salts to triphenylmethyl. Triphenylcarbinol is slightly soluble in a very concentrated aqueous solution of zinc chloride saturated with hydrogen chloride; a colored precipitate is formed on adding vanadous chloride to this solution. The existence of triphenylmethyl in this precipitate was demonstrated both by the color of a benzene solution and by the isolation of the peroxide obtained on shaking the solution with air. A solution of triphenylcarbinol in concd. sulfuric acid is also reduced by vanadous chloride, a precipitate containing triphenylmethyl being formed.

In this preliminary paper we shall not enter into a discussion of the much debated subject of the constitution of salts of triphenylcarbinol² nor of the relative advantages of the oxonium or carbonium formulas for the pyrylium and xanthylium compounds.³ For our present purposes we may consider that *in solution* the "oxonium" and the "carbonium" salts are present, at least to some extent, as polar compounds; if this is so, the reduction of such salts to free radicals is comparable to the reduction of stannous chloride to metallic tin by the action of chromous chloride. These processes appear to be reversible and to consist essentially of the gain or loss of an electron from a certain group of atoms which can function either as a positive ion or as a free radical, thus: $(C_6H_5)_3C^+ + E$ $C_6H_5)_3C^-$.

Recent investigations have shown that a number of reversible organic processes which can be formulated in terms of electronic transfer give definite potentials.⁴ Preliminary experiments indicate that reduction potentials of certain organic salts to free radicals can also be measured; such potentials of free radicals are analogous to the single potentials of

the metals. We hope to deal with this subject in more detail in another paper.

Free Radicals and Bimolecular Reduction

The extensive work of Gomberg and others on free radicals has shown that the so-called free radical is in solution an equilibrium mixture of the monomolecular free radical and its bimolecular association product. In the case of triphenylmethyl the following equation represents one of the equilibria which are involved (we will neglect in this discussion the tautomeric equilibria involving color changes). $2(C_6H_5)_3C^- \longrightarrow (C_6H_5)_3C^ C(C_6H_5)_3$. The extent of the dissociation of the bimolecular form is a function of the nature of the groups attached to the central carbon atom. This being the case, one would expect that in many cases in which "onium halides" were reduced to radicals the free radicals would polymerize completely to the associated form; if this associated form was not appreciably dissociated in the solution, simple bimolecular reduction would apparently have occurred. However, if the first reduction product should separate rapidly in the solid form before it had wholly associated it might be possible to obtain a solid "free" radical whose existence in solution could not be demonstrated. We believe that we have realized such a case in the reduction of the salts of xanthenol (V) with vanadous chloride. When a very dilute solution of xanthenol in concd. hydrochloric acid is treated in the cold with vanadous chloride a pink precipitate is immediately formed. This can be filtered off and is stable for a few hours in the air but gradually becomes colorless. The colorless solid is bixanthyl⁵ (VI).

$$O \xrightarrow{C_6H_4} CHOH \qquad O \xrightarrow{C_6H_4} CH-CH \xrightarrow{C_6H_4} O$$

$$(VI) \qquad (VII)$$

bright pink precipitate is washed with water, sucked dry and then dissolved in chloroform in the absence of air (in a special apparatus) a momentary color is produced in the chloroform which fades in a few seconds. The chloroform solution on evaporation yields bixanthyl. This color change is a strong indication that the solid which is precipitated on the addition of vanadous chloride contains some "free" xanthyl radical (VII) which dissolves in chloroform with a brown color and then immediately and completely polymerizes to the colorless bixanthyl. If our interpretation of these color changes is correct a new method is available for mak-

⁵ Fosse, Bull. soc. chim., [3] 35, 1005 (1906).

ing solid organic radicals which are not free in solution. We are now investigating the extension of this method as well as the closely allied problem of the reduction of various types of aldehydes and ketones with vanadous and chromous salts.

The reduction of pyridinium and acridinium salts should be entirely analogous to the reduction of pyrylium and xanthylium compounds. Indeed, Cone showed some years ago that by the action of metallic zinc on an aqueous solution of N-phenyl-phenylacridinium chloride a free radical was formed. This reaction can be formulated either as the general reaction between a metal and the solution of an organic chloride giving a free radical or as a case of reduction brought about in this case by a metallic reducing agent. There is one difference between the reduction of pyrylium and pyridinium compounds: the reduction products of the former series whether as free radicals or in the bimolecular form no longer have basic properties; they therefore precipitate from acid solution on the addition of vanadous chloride. This would not be the case with the nitrogen compounds, since even in the reduced form the trivalent nitrogen would have basic properties. It is, therefore, not surprising that on the addition of vanadous chloride to benzylpyridinium chloride (VIII) there is no apparent change; on making the solution alkaline, however, and extracting with ether, the bimolecular reduction product, N',N-dibenzyl-tetrahydrodipyridyl (IX), is obtained. By analogy with the carbonium compounds

there is every reason to believe that the first step in the process is the formation of the free radical, benzylpyridinium, but since this is soluble in the acid solution it immediately polymerizes to the bimolecular form.

If we formulate the relationship between a free radical and the corresponding "onium salt" in terms comparable to the single electrode potential of a metal, it is obvious that all reducing agents whose potentials are below the potentials of the free radicals should cause the precipitation of the radical. In the case of those compounds which we have so far investigated, vanadous chloride has a sufficiently low potential (normal potential about —0.200 referred to hydrogen) to cause this reaction; titanous salts (about —0.040) do not cause a rapid reduction. Chromous

6 Cone, This Journal, 34, 1695 (1912); 36, 2101 (1914).

⁷ Weitz, [Ann., 425, 202 (1921)] and Emmert [Ber., 53, 370 (1920)] reported that they had obtained this free radical, but later [Ber., 55, 2322, 2864] showed conclusively that the colored substance was bimolecular.

chloride (—0.400) reduces the substances in question to free radicals just as does vanadous chloride, but because of its relative stability we have preferred to use the latter reagent. If too powerful a reducing agent be employed in such a process the free radical may be further reduced to the hydrogen compound, just as arsenic and antimony may be reduced to their hydrides. As in inorganic chemistry, the solubility and dissociation of the various factors and products in an electrochemical reaction are quite as important as the value of the normal potentials. Until we have such information, together with the potentials of the free radicals, it is profitless to pursue further the electrochemical aspects of these reactions.

Experimental Part

Reduction of 2,4,6-Triphenylpyrylium Chloride.—The ferric chloride double salt of this chloride was prepared according to the method of Dilthey⁸ and from it the pseudo base and the iron-free chloride. Both the chloride and the ferric chloride double salt are reduced by vanadous chloride in the same manner, except that with the latter compound a certain amount of vanadous chloride is used up in reducing the ferric to ferrous salt. Because the ferric salt is more conveniently prepared it was used in most of the experiments of which the following is typical.

One g. of the ferric chloride double salt was dissolved in 125 cc. of air-free water in a 200cc. Erlenmeyer flask. The flask was swept out with carbon dioxide and 0.1 N vanadous chloride added from a buret while the flask was constantly shaken. A reddish solid soon began to precipitate; vanadous chloride was added in excess (until no further precipitate formed). The mixture was then filtered through a Gooch funnel in an atmosphere of carbon dioxide and washed with air-free water.

The red-brown solid thus obtained dissolved in chloroform or benzene with a red color; when shaken with air the solution became colorless or yellow. When suspended in water and treated with ferric chloride solution the brown solid went into solution rapidly and the characteristic yellow double salt of pyrylium chloride and ferric chloride separated on the addition of hydrochloric acid. Several attempts to dry the precipitate in an atmosphere of carbon dioxide were unsuccessful, either because of failure to exclude air completely or because the compound slowly decomposed; the resulting solid was a mixture of yellow and blackish materials which did not show the characteristics of the original compound.

A number of quantitative experiments were carried out in which the precipitate after it was washed was oxidized with ferric alum in an atmosphere of carbon dioxide either with or without the addition of a little benzene to facilitate the solution. After the solution had been thoroughly shaken for 5 minutes the excess of ferric salt was titrated with standard titanium chloride using ammonium thiocyanate as an outside indicator. The following summarizes the results which are very variable but indicate

⁸ Dilthey, J. prakt. Chem., 94, 65 (1916).

that one equivalent of hydrogen is involved as a maximum. The figures represent moles of ferric salt required to oxidize the precipitate formed from one mole of double salt: (1) freshly precipitated, 0.92, 0.74, 0.59, 1.00; (2) after 14 hours in carbon dioxide, 0.50; (3) after 3 days in carbon dioxide, 0.29.

Reduction of 9-Phenylxanthylium Chloride.—Half a gram of 9-phenylxanthenol was dissolved in 20 cc. of concd. hydrochloric acid and 5 cc. of water by gently warming the mixture. The resulting orange-colored solution was cooled, filtered from a very small amount of insoluble material by means of glass wool and placed in a separatory funnel filled with carbon dioxide. An excess of 0.1 M vanadous chloride was run in and a brown precipitate was immediately formed. Chloroform (about 20 cc.) was then added and the mixture shaken; the heavy precipitate completely dissolved, imparting a deep red color to the chloroform. This solution was then run into another vessel and shaken with air; the color rapidly vanished. On evaporation of the chloroform a white solid was obtained which was freed from a small amount of oily material by washing it with ether. It melted sharply with decomposition at 208–209° and weighed 0.25 g. Recrystallized from benzene, it melted at 211° and was identified as phenylxanthyl peroxide by comparison with a sample prepared according to Gomberg's procedure.

Reduction of Triphenylcarbinol.—A solution of 0.2 g. of triphenylcarbinol in a mixture of 5 cc. of coned. hydrochloric acid and 10 cc. of zinc chloride solution (100 g. in 50 cc. of water) saturated with hydrogen chloride at a temperature of 70-80°, was cooled and filtered through glass wool; vanadous chloride was added to it in an atmosphere of carbon dioxide. A reddish precipitate was formed which was rapidly filtered off and dissolved in benzene in the absence of air. A brown solution was formed, the color of which was discharged by shaking with air. The benzene solution on spontaneous evaporation yielded a small amount of white solid, insoluble in ether, which melted sharply to a red melt at 180-182° (triphenylmethyl peroxide melts at 185-186°). A solution of 0.5 g. of triphenylcarbinol in 20 cc. of 95% sulfuric acid was treated with vanadous chloride solution; a red precipitate formed. The evolution of hydrogen chloride somewhat hindered the carrying out of this reaction; we propose to use vanadous sulfate for such reactions in future work. The sulfuric acid suspension of the reddish precipitate was poured onto cracked ice and the mixture filtered as soon as the ice had melted. The precipitate dissolved in benzene with the development of color; the color disappeared when the solution was shaken with air and the peroxide was obtained by evaporating the benzene solution and treating the residue with ether.

Reduction of Xanthylium Chloride.—A solution of 2 g. of xanthenol in 50 cc. of concd. hydrochloric acid saturated with hydrogen chloride at 0° was filtered from a small amount of material by passing it through glass wool. The light brown solution was treated with an excess of vanadous chloride in the usual manner and the resulting precipitate rapidly filtered in the air and washed with water. A pink solid was thus obtained; attempts to dry it in nitrogen without loss of color were unsuccessful. Recrystallized from acetone after it had become colorless it yielded 1.3 g. of bixanthyl⁵ (m. p., 204–205°) and 0.2 g. of oily material. In another experiment the precipitate was immediately dissolved in chloroform, the chloroform solution showing a faint red color for a few seconds and then becoming colorless. Bixanthyl was obtained in a good yield from this solution. To ascertain whether or not the rapid fading of the color of the solution was due to oxidation, the solution in chloroform was carried out in the absence of air. Some of the freshly precipitated compound was placed in one leg of a wide Y-tube and chloroform placed in the other leg. The apparatus was then repeatedly evacuated and filled with nitrogen (free from oxygen). The tube was then tilted and the chloroform

rapidly run onto the precipitate which dissolved with a momentary red color, forming after a few seconds a colorless solution. This is strong evidence that the color change was not due to oxidation but to polymerization.

Reduction of Benzylpyridinium Chloride.—A solution of 2 g. of benzylpyridinium chloride in 50 cc. of water was treated with 50% more than the amount of vanadous chloride equivalent to two hydrogen equivalents. No precipitate formed but the vanadous chloride was evidently oxidized, as the first portion of it rapidly changed color. The solution was made strongly alkaline and the solution containing a suspension of inorganic hydroxides and organic material was repeatedly extracted with ether. On evaporation a brown solid was obtained which on washing with alcohol became nearly white. It melted at 74-83° and was identified as N,N'-dibenzyl-tetrahydro-dipyridyl by the very characteristic blue color which its alcoholic or acetone solutions acquired when warmed in air.

Summary

- 1. Vanadous chloride reduces triphenylpyrylium chloride, forming a colored substance insoluble in water that behaves like a free radical. The same reagent reduces phenylxanthylium chloride to the free radical, phenylxanthyl, previously prepared by Gomberg.
- 2. Triphenylcarbinol in concd. hydrochloric acid or sulfuric acid solution is reduced to triphenylmethyl by vanadous chloride.
- 3. Xanthenol in concd. hydrochloric acid is reduced by vanadous chloride to bixanthyl. The color of the product indicates that a free radical is first formed which is stable only in the solid state. Benzylpyridinium chloride is reduced to a bimolecular product; no insoluble compound is formed in contrast to the behavior of the oxonium and carbonium chlorides.

CAMBRIDGE 38, MASSACHUSETTS

NEW BOOKS

The Theory of Allotropy. By A. Smits, Ph.D., Professor of Chemistry in the University of Amsterdam. Translated from the German with the Author's sanction by J. Smeath Thomas, D.Sc., Senior Lecturer on Chemistry in the University of Liverpool. (Text-Books of Physical Chemistry, edited by Sir William Ramsay and F. G. Donnan.) Longmans, Green and Company, 55 Fifth Avenue, New York; London, Toronto, Bombay, Calcutta and Madras; 1922. xiii + 397 pp. 239 figs. 22 × 14 cm. Price \$7.00 net.

Many of the writers of scientific papers published in the Netherlands seem tacitly to assume that the reader is thoroughly familiar with the writer's previous papers and can therefore without explanation apprehend the precise meaning of terms and symbols. In a series of papers this may be unavoidable, but a book made from them should surely include a fundamental discussion comprehensible to the reader not already a specialist in the topic. American readers of this book will find the explanatory matter inadequate, and the general mode of treatment is not attractive enough to persuade many of them to proceed far with the task of reading

it comprehendingly. Part of the difficulty is inherent in the subject; but the drier the subject, the more care must one take in exposition. The first two pages are designed to set forth the basis of the theory, but do it so curtly that to many readers they would convey little. On the third page the author plunges into his subject and devotes about half of the book to a theoretical discussion of various possible cases, using the methods of Gibbs, which are more familiar to Hollanders than to Americans. In the latter half he takes up a number of cases which have been investigated experimentally and considers the application of the theory to account for electrochemical phenomena, passivity of metals in particular. The essence of the theory is that allotropy is a case of tautomerism; that an allotropic substance, though in many respects it behaves as a one-component system, is in reality a mixture of two molecular species or pseudocomponents which in general are in equilibrium with each other. This hypothesis is very helpful in accounting for the phenomena observed in systems such as sulfur where the observed melting temperature, for instance, depends upon the previous history of the sample of sulfur; but there is a question as to how far one is practically justified in extending it to all of the cases to which the author applies it. To the student specifically interested in the subject of allotropy the book will be welcome, but it cannot be commended to any other class of readers.

JOHN JOHNSTON

Anorganische Chemie: ein Lehrbuch zum Weiterstudium und zum Handgebrauch. (Inorganic Chemistry: a textbook for the more advanced student and for reference.) By Dr. Fritz Ephraim, Professor at the University of Berne. Second and third editions, revised. Theodor Steinkopff, Residenzstr. 12 b, Dresden-Blasewitz, 1923. viii + 742 pp. 55 figs. 24.5 × 16.5 cm. Price unbound \$2.00; bound \$2.40.

It is not surprising that a third edition of this excellent handbook has been required. In it, account has been taken of the most recent advances in this field, and numerous minor improvements have been made. The book is, however, substantially unchanged from the first edition.

It is too bad that so good a book as this is printed on such miserable paper.

ARTHUR B. LAMB

Laboratory Exercises in Inorganic Chemistry. By James F. Norris, Professor of Organic Chemistry, Massachusetts Institute of Technology, and Kenneth L. Mark, Professor of Chemistry, Simmons College. International Chemical Series, H. P. Talbot, Ph.D., Consulting Editor. McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York; 6 and 8 Bouverie Street, E. C. 4, London, 1922. x+548 pp. 16 figs. 21 × 14 cm. Price \$2.00.

This book is intended for "the student who has had a good training in Chemistry in the high school, and who should have his interest stimulated in his college course, and should be given an opportunity to extend his experience." In carrying out this purpose, the authors have avoided the mere repetition of the more purely illustrative experiments performed in the high school, and have introduced a large number of experiments to emphasize the general principles of chemistry, as the following titles of the first 20 experiments will show.

Physical and Chemical Changes; Mixtures and Pure Substances, (an important topic often slurred in elementary courses); Oxygen; Hydrogen; Quantitative Studies of Chemical Reactions; Water; Chlorine; Hydrochloric Acid; Hydrogen Peroxide; Properties of Liquids and Solids; Carbon and Its Compounds; Acids, Bases, and Salts; Solutions; Chemical Equilibrium; Sulfur and Sulfides; Oxides and Acids of Sulfur; Nitrogen and the Atmosphere; Ammonia; Acids and Oxides of Nitrogen; Atomic and Molecular Weights. The experiments which follow take up Groups 7 and 5, organic compounds, silicon and boron, and then the metals, but include also experiments on the physical properties of the metals, chemical properties of the metals, and electrochemistry. Each assignment is preceded by a discussion which should enable the student to understand the general purpose of the experiments. The experimental directions are clear, and involve simple apparatus.

The most striking feature of the book is the list of questions upon each experiment. The authors have resisted the temptation to do all the thinking for the student by wording the questions so as to indicate the answer. The questions are, on the contrary, well calculated to stimulate the student to accurate observation and clear reasoning. In the opinion of the reviewer, this course represents a noteworthy effort to give the student the proper foundation for the understanding of modern chemistry.

TOEL H. HILDEBRAND

Die Physikalische Chemie in der Inneren Medizin (Physical Chemistry as Applied to Internal Medicine). By Prof. Dr. H. Schade, Director of the Physico-chemical Division of the Medical Clinic, University of Kiel. Theodor Steinkopff, Dresden and Leipzig. 1921. vii + 569 pp. 107 figs.

The development of physical chemistry as an independent entity has determined great progress in many fields of thought. Among these, the medical sciences upon which the art of healing is based, have been notably stimulated and expanded by the application of these concepts and generalizations. Recognizing the import of scientific development to the practice of the art, the author has prepared a non-mathematical summary for the use of physicians and students. The introductory chapters are devoted to an exposition of certain fundamental concepts in the physico-chemical field. In the main the facts are clearly presented, at times, excellently, and the summary solution of certain of the still disputed questions of theory will probably not prove disquieting to the author's prospective

clientele. As an example may be cited the author's opening sentences (p. 2) in which solutions are divided into three "sharply defined" types. From time to time, the author pauses to emphasize the validity of purely materialistic concepts. One wonders why his optimistic prophecy concerning cell morphogenesis is not supported by quotation from Bastian's ingenious—and meaningless—experiments. The major portion of the volume is concerned with the principal thesis, the pathological conditions discussed being arranged chiefly in a topographical classification. The blood, alimentary canal, liver, kidneys, lungs, circulatory and nervous systems, are among the topics treated. It is to be regretted for the authority of the book that the access of the writer to literature other than that in German, was so limited. While the disruption of the war could readily explain a number of the omissions, others cannot be so reasonably condoned. To cite a single instance, a discussion of gaseous metabolism without reference to Benedict or duBois must fall short of a complete exposition of the topic. Of the author's own prolificity, frequent quotation leaves no doubt. Particularly is he indebted to his earlier publication on "The Significance of Catalysis for Medicine."

Certain earlier generalizations which have lost a portion of their original significance in the light of later experience are apparently regarded as still to be designated as laws ("gesetze").

In the somewhat frequent application of this term to generalizations of varying degrees of validity one is inevitably reminded of the Dooley saying of two decades ago concerning "buildings called sky scrapers—but not by the sky."

A third portion of the book is devoted to a description of the technical details of certain physical chemical methods which have been applied to diagnostic procedures. Many of the illustrations are familiar to those who have had occasion to consult the catalogs of several well-known purveyors of apparatus.

To summarize briefly: the book shows evidence of the expenditure of much labor. There is, however, a distinct lack of critical evaluation of much included material. With the several excellent treatises in this field from authors evidencing a more catholic taste in current literature there does not seem to be a searching need for the present volume.

The make-up of the book reflects the material difficulties with which Germany is now contending.

A. W. Rowe

Die Physikalische Chemie in der Inneren Medizin. Die Anwendung und die Bedeutung Physikochemischer Forschung in der Pathologie und Therapie fur Studierende und Aerzte. (Physical Chemistry as Applied to Internal Medicine. The Application and Significance of Physicochemical Studies in Pathology and Therapeutics. For Students and Physicians.) By Prof. Dr. H. Schade. Thirdd enlarge

and revised edition. Theodor Steinkopff, Dresden and Leipzig, 1923. viii + 605 pp. 120 figs. 24.5×16 cm. Price unbound \$2.80; bound \$3.70.

While the preceding review was in press, a third and revised edition of the work has appeared. Beyond the expansion of certain sections by the inclusion of more recent citations, chiefly local in origin, no significant changes have been made. A number of minor inaccuracies occurring in the first edition remain uncorrected. The insertion of the index to Part I in the body of the book is an innovation of dubious value. The quality of press work and stock is improved but still leaves much to be desired.

A. W. Rowe

Practical Physiological Chemistry. By Philip B. Hawk, M.S., Ph.D., Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. Eighth edition, revised. P. Blakiston's Son and Co., Philadelphia, U. S. A., 1923. xvi + 693 pp., 6 full page color plates and 197 figs. Price \$5.00.

Since the first appearance of this work in 1907, it has passed through a number of editions until in 1923, the 8th revision appears. Originally intended as a laboratory manual, it has grown steadily until it is now a somewhat compendious compilation of laboratory methods. This growth, while it has enriched the volume as a work of reference has, in large measure, nullified the original purpose. A patent cause of the embarrassment of riches is the attempt to unite in one volume the materials for a course in biochemistry suitable for collegiate instruction, with those of a diagnostic technical character designed for the instruction of medical students. The chapters on "Gastric Analysis" and "Respiration and Acidosis" are eminently cases in the latter point. This enlarges the book far beyond any practical compass as a teaching manual, and entails a repetition of early experiments under later captions.

In the chapter on "Metabolism" it is a little difficult to understand the inclusion of 20 pages of animal experimentation, although the lucidity of the text and the attractiveness of the illustrations make it both interesting and stimulating. It is to be regretted also that in the selection of analytical methods the author does not exercise a larger measure of critical scrutiny, thereby lessening the somewhat bewildering multiplicity of procedures for the determination of a single substance. To summarize, in its present form the book occupies that debatable middle ground between the real laboratory manual designed for the conduct of a specific course, and the encyclopedic compendia of laboratory methods such as so frequently appear under the editorship of the prolific Abderhalden.

On the other hand, the book possesses many admirable qualities. The introductory paragraphs of each chapter are most judicious summaries of the facts and theories to illustrate which the experiments are designed. The author enjoys a most happy faculty of presenting his matter with clarity, simplicity and accuracy. These qualities, applied as they are to

the individual directions for experiment, offer the maximum of assistance to the student, while in no sense restricting individual performance. The illustrations are numerous and admirably chosen. The summaries in systematic form cannot fail to appeal to teacher and student alike. The appendix, repeating the directions for preparation of reagents and solutions, originally presented as footnotes, is an excellent feature. The index is complete and well arranged.

If the author could be persuaded to divide his material into two volumes, thus conserving the needs of his dual public, the objections to the present text would be in large measure eliminated. And teachers and students in the several fields of pure and applied biochemistry would be greatly enriched thereby.

From the publisher's standpoint the book is handsomely and durably fashioned. Freedom from typographical error is an added attraction.

A. W. Rowe

The Chemistry of Tuberculosis. By H. Gideon Wells, M.D., Lydia M. DeWitt, M.D., and Esmond R. Long, Ph.D., Professors in the University of Chicago and in Rush Medical College. Williams and Wilkins Company, Baltimore, U. S. A., 1923. vii + 447 pp. 7 figs. 23.5 × 15.5 cm. Price \$5.00, United States; \$5.25, Canada; \$5.50 other countries; net, postpaid.

This volume is the outgrowth of the bibliographical phase of the studies on tuberculosis carried out at the Otho S. A. Sprague Memorial Institute. The authors state in the preface that it supplements the earlier monograph by Ott published in 1903. They could with full justice have claimed that, in large measure, it replaces it. The majority of citations are from the literature of the last two decades, during which time refinement and development of chemical methods have rendered obsolete much of the carefully compiled but regrettably erroneous data of the earlier period. The application of physicochemical concepts and generalizations to the problems of biology has also wrought changes of far reaching import and significance. In the present volume, while the cited literature is by nomeans exhaustive, this is evidently the result of a nice discrimination. Particularly to be commended is the just and balanced use of the authors' own material.

Pertinent and significant reference is naturally made, but there is wholly lacking that textual absorption that is an unfortunate and limiting feature of certain similar publications. Recognizing the existence of two schools of practice, it may be suggested that the uniform inclusion of the author's name with the literature citation would be an improvement. Further advantage might be secured by an alphabetical arrangement of all citations in an appendix.

The book is divided into unequal thirds, each dealing with a special phase of the topic. The introductory chapters on the chemistry of the

acid fast bacteria are written by Dr. E. R. Long. The chemical composition of the bacillus and its various metabolic activities are fully treated, and a special chapter is devoted to the property of acid fastness. The second section, which comprises approximately half of the volume and deals with a discussion of the chemical changes in the host, is from the pen of the senior author. Readers who have enjoyed the succinct and graphic summaries in the author's "Chemical Pathology" will derive equal pleasure from the present volume. Restatement of citations is here and there observed, but a fresh connotation usually warrants the repetition.

The inclusion of brief but lucid comparisons and contrasts with pathological states other than that of the thesis adds to the value of the book to the general scientific reader, and attests quietly and convincingly the author's breadth of perspective.

The concluding chapters of the book, written by Dr. L. M. DeWitt, deal with the chemotherapy of tuberculosis. As is implied in the character of research to which the Sprague Institute is dedicated, citation from local sources is here more frequent. With its intrinsic connection with the problem in hand, however, it but emphasizes the scope and value of the studies which have there found their genesis.

All in all, the authors have rendered a very real and definite service to the scientific public, for while the individual worker must go to his original sources, the summary here critically presented, should make unnecessary many hours of fruitless labor.

Mechanically, the press work is excellent, and there is an almost complete absence of typographical error. The probable appearance of a new edition in the near future will, it is hoped, offer opportunity for the use of a more substantial binding.

THE SOLUBILITY AND SURFACE ENERGY OF CALCIUM SULFATE

By Merle I. Dundon¹ and Edward Mack, Jr. Received April 9, 1923

It is well known in a qualitative way that the solubility of very fine particles is greater than that of coarse ones. This is exemplified in the ordinary custom of digesting precipitates in order to facilitate their filtration. The importance of having available some quantitative knowledge of just how solubility depends on size is very apparent. Such data are needed in elucidation of the surface-energy relations of solids such as are now involved in the study of the colloidal state. In spite of its importance, however, the only available experimental data in this field are those of Hulett² for calcium and barium sulfates, and for mercuric oxide, and even these are admittedly qualitative.

In the present paper and the one which follows,^{2a} we have repeated some of Hulett's work and have extended his general experimental method to several other substances in an effort to obtain reliable values for their surface energy.

- ¹ Grasselli Fellow, 1921-1922.
- ² Hulett, Z. physik. Chem., 37, 385 (1901); 47, 357 (1904). It is true that Marian Jones and J. R. Partington [J. Chem. Soc., 107, 1019 (1915)] measured the increased solubility of small calcium sulfate particles. Sauer [Z. physik. Chem., 47, 160 (1904)] also mentions incidentally the increased solubility of finely pulverized calomel in connection with the use of a calomel electrode. But it is not reported in either of these papers that the size of the particles was measured. It should be noted also that F. C. Thompson [Trans. Faraday Soc., 17, 391 (1922)] by quenching an iron-carbon alloy at 780°, then tempering part of it at 500° and another part at 650°, obtained cementite grains of different sizes. He determined the concentration of the carbon dissolved in the iron in the two cases by measuring the electrical resistance, and calculated an interfacial tension of 1350 dynes/cm.

Theoretical Part

Surface energy, σ , has been calculated by Hulett and by Freundlich, by substitution in the Ostwald-Freundlich equation,³

$$\frac{RT}{M} \ln \frac{S_2}{S_1} = \frac{2\sigma}{\rho} \left(\frac{1}{r_2} - \frac{1}{r_1} \right)$$
 (1)

where R is the gas constant, T the absolute temperature, M the molecular weight of the solid in solution, ρ the density of the solid, σ the surface energy per unit surface between the solid and its solution, and S_2 and S_1 are the solubilities of the particles of radii r_2 and r_1 , respectively. In the derivation of this equation it is assumed that the particles are spherical, that the dissolved solid obeys the gas laws, and that σ and ρ are independent of the size of the particles. Equation 1 does not hold for dissociated substances. Jones takes into account the dissociation of the dissolved substance by combining Equation 1 with the equation of Storch, which is

$$\frac{(1-\alpha)}{v} = K\left(\frac{\alpha}{v}\right)^m \tag{2}$$

where α is the degree of dissociation, v is the dilution and K and m are constants. When m is 2, Storch's equation becomes the familiar Ostwald dilution equation. The equation which Jones derived, by a combination of Equations 1 and 2 and by integrating between the limits α_1 and α_2 , is

$$\frac{2\sigma}{\rho} \left(\frac{1}{r_2} - \frac{1}{r_1} \right) = \frac{RT}{M} \left[(n-1) (\alpha_1 - \alpha_2) - \frac{n}{m-1} \ln \frac{1 - \alpha_1}{1 - \alpha_2} + \frac{m}{m-1} \ln \frac{\alpha_1}{\alpha_2} \right]$$
(3)

where n is the number of ions formed from the dissociation of one molecule. While this equation is theoretically sound, its practical application is complicated by the fact that concentrations are expressed only in terms of dissociation and the constant m in Storch's equation. Inasmuch as small differences in dissociation correspond to rather large changes of concentration, small errors in expressing dissociations are quite serious.

In these fundamental derivations the ordinary expression for osmotic work done is $\frac{RT}{M} \ln \frac{p_2}{p_1}$ for one mole of dissolved solute. Then, if a substance is dissociated and we assume that this dissociation is constant during the process, Equation 1 becomes

$$(1-\alpha+n\alpha)\frac{RT}{M}\ln\frac{S_2}{S_1}=\frac{2\sigma}{\rho}\left(\frac{1}{r_2}-\frac{1}{r_1}\right) \tag{4}$$

³ First derived in its most general form by Willard Gibbs in 1876, "Scientific Papers," Longmans, Green and Co., 1906, N. Y., vol. I, p. 315.

⁴ William Jacob Jones [Ann. Physik, 41, 441 (1913)] has considered the influence of various geometrical forms instead of the spherical particles assumed in the general equation.

⁵ W. J. Jones, Z. physik. Chem., 82, 448 (1913).

⁶ Storch, ibid., 19, 13 (1896).

Values obtained by this simple equation approximate closely to those calculated by means of the rigorous equation of Jones, the differences being very small in comparison with the errors inherent in the data.

There is another point in this connection which is important. In substituting numerical values for the radii in the expression $\frac{2\sigma}{\rho}\left(\frac{1}{r_2}-\frac{1}{r_1}\right)$, r_2 is the radius of the smaller and more soluble particles, and is, of course, measured by microscopic observation; r_1 represents the radius of a large particle, in equilibrium with its own saturated solution. In Hulett's work (and also in the present work) this saturated solution containing the large particles was simply a saturated solution of the substance in equilibrium with large crystals. Since the crystal surfaces were flat, $1/r_1$ is $1/\infty$. It is true that Hulett's results seemed to show that particles 2μ in diameter were also in equilibrium with the saturated solution of the crystals. But one cannot be absolutely certain of the equilibrium, and if it is a question of choosing between $1/\infty$ and $1/2\mu$ there can be no doubt that it is preferable to write $1/\infty$ into the equation. In this case, Equation 4 assumes the form

$$(1 - \alpha + n\alpha) \frac{RT}{M} \ln \frac{Sr}{S} = \frac{2\sigma}{\rho r}$$
 (5)

and this is the equation which we have used throughout our work in calculating the surface energy.

In an interesting paper, Marian Jones and J. R. Partington have attempted to test the validity of Equation 1 at 20°, 40° and 60°. Taking the known concentrations of saturated calcium sulfate solutions in equilibrium with gypsum crystals, they substitute these values for S_1 in Equation 1 and calculate S_2 for the respective temperatures and for various values of r_2 , setting $r_1 = \infty$, and making use of W. J. Jones' surface-energy value, 1050, calculated from Hulett's data. They have not measured the size of their particles, but have assumed a radius of 1μ , because their experimentally determined solubilities fit their calculated solubility curve for particles of this size. The surface-energy value, 1050, which takes into account the dissociation of the calcium sulfate, has unfortunately been substituted in Equation 1, which does not hold for dissociated substances. The result is that all of their calculated solubilities and radius values are much too high. This error is evident from the fact that their fine particles which give an increased concentration of 4.6% at 20° are considered to be of the same size as were found by Hulett to show no increased solubility, although their own calculations are based on Hulett's data.8

⁷ Jones and Partington, J. Chem. Soc., 107, 1019 (1915).

⁸ It has seemed desirable to call attention to the difficulties with the conclusions reached by Jones and Partington, because the substance of their work has already been incorporated into two well-known chemical texts.

Experimental Part

The method we have employed in measuring the increased solubility of small particles of calcium sulfate is essentially the same as that of Hulett. Into a saturated solution of calcium sulfate in equilibrium at 25° with large crystals, a quantity of the finely powdered calcium sulfate was introduced. The increase in concentration, and the return to the original concentration were noted by conductivity measurements. In order to calculate the concentration of a solution of a dissociated substance from the conductivity by means of the formula, $\frac{\text{millimoles}}{\text{liter}} = \frac{k}{2\alpha\Lambda_{\infty}}$, it is necessary to know the degree of dissociation α . For strong electrolytes Storch's dilution law holds and can be applied to supersaturated solutions. That equation, however, contains two unknowns and cannot be solved for α , but corresponding values for concentration (1/v) and dissociation (α) may be determined by the method of trial and error. this way values of 1/v and α corresponding to the conductivity of the solution in question are found. A at 25° was taken as 126. Concentrations of calcium sulfate can also be calculated from the conductivity value at 25° by the empirical formula of Hulett, $\frac{\text{millimoles}}{\text{liter}} = -0.354 +$ $5211 (k_{25}) + 841400 (k_{25})^2$.

Calculations to millimoles per liter for two supersaturated solutions gave by the first method 15.59 and 48.84, and by Hulett's equation 15.54 and 49.35, respectively. In view of the evident agreement the simpler formula of Hulett was used in all subsequent calculations, for even though absolute values might be slightly different the percentage increase would be the same.

Preparation of the Salt.—Large crystals of calcium sulfate were prepared by allowing solutions of calcium chloride and of sulfuric acid to drop slowly into 3 liters of hot, well-stirred, distilled water. The precipitate was then thoroughly washed eight times, using 2 to 3 liters of distilled water each time. In this way a pure sample of crystals $20-50\mu$ long was obtained. Analysis showed that its water content was 21.1%. A second analysis checked exactly with the first. The theoretical water content of the dihydrate, CaSO₄. $2H_2O_7$, is 20.93%.

The Kohlrausch type of conductivity cell with platinized electrodes that was used could be shaken violently by hand immediately upon addition of the powder.

Experiment 1.—Some of these large crystals were ground by hand in an agate mortar to a fairly uniform average size of 0.3μ . Part of this powder (0.4 g.) was added to about 40 cc. of the saturated solution in a conductivity cell and in one minute the conductivity rose from the original value of 2208×10^{-6} to 2616×10^{-6} . After two days it had returned

⁹ Hulett, Z. physik. Chem., 42, 581 (1903).

to 2276, and after six days to 2213 \times 10⁻⁶. The only large crystals, with which the final solution was presumably in equilibrium, were those large fragments introduced along with the fine powder. When calculated to concentration values, the increase was about 24%.

Analysis of a portion of the powder which had been ground in the agate mortar, showed that its water content was only 12%. Evidently, the grinding treatment had partially dehydrated it. This effect has been observed by Sullivan and Steiger, 10 who reduced the water in gypsum to about 5% by long grinding. Since it is well known 11 that dehydrated calcium sulfate is much more soluble than the dihydrate, it may be true that part, at least, of the observed increase in solubility noted in this experiment may have been due to the presence of the dehydrated material. Hulett, in fact, was careful to call attention to such a possibility. Practically the same result that has been noted in this experiment with precipitated calcium sulfate, has also been found with natural gypsum. With ground gypsum particles 0.3μ in diameter and a water content of 15%, an increase in concentration of 28% was observed.

Experiment 2.—The greater solubility of the dehydrated material may be shown in a very striking way. When calcium sulfate which has lost a few per cent. of its water content is added to a drop of water under the microscope, long needle-like crystals of the dihydrate form rapidly, thus showing a high degree of supersaturation. But the needles do not form if the added powder contains its full amount of water of crystallization, even though it be very finely divided.

Experiment 3.—To the same saturated solution in equilibrium with the large crystals used in Expt. 1, were added some of these same large crystals which had been dehydrated by heating. The crystals were not ground. The conductivity moved from the original value of 2208×10^{-6} to 2450×10^{-6} in one day, and in two days to 2520×10^{-6} . When filtered and seeded with the original hydrated crystals, the conductivity returned after four days to practically its original value. The question at once arose as to whether or not heating the crystals resulted in pulverization by decrepitation. Microscopic examination of the dry crystals failed to show the presence of fine particles, and the very slow rate of increase of the conductivity also indicated that small particles were not present.

This experiment shows that it is possible to increase the concentration without powdering the calcium sulfate, if it is dehydrated. It is interesting to note, incidentally, what happens to the dry crystals which have been dehydrated, when a drop of water is added to them on a microscopic slide.

¹⁰ This observation is given by W. F. Hillebrand, This Journal, 30, 1120 (1908).
Compare John Johnston, Rec. trav. chim., 42, 850 (1923).

¹¹ Marignac, Ann. chim. phys., (5) I, 274 (1874). Cavazzi, Industria chimica, 1906, 366 (1906).

They are at once broken up into much smaller crystals, as though the water violently works its way with a disruptive force into porous places which have been produced in the crystals by the heat treatment.

Experiment 4.—It is evidently not at all an easy matter to grind calcium sulfate crystals without causing partial dehydration. An attempt was made to do this by grinding the precipitated crystals between two glass plates wetted with petroleum ether. The powder analyzed 21.1% water. Most of it was about 0.5μ in diameter, with very little smaller than that. The increase in concentration obtained was 4.8%.

The crystals can be ground between glass plates without the addition of petroleum ether and the powder will show by analysis its full water content, but it is difficult to obtain powder even as small as 0.5μ , because of the stickiness and the great resistance to rubbing.

Experiment 5.—In a further attempt to prevent dehydration on grinding, some clean natural gypsum crystals were ground in an agate mortar in a small room where the air was kept saturated by vapor from boiling water. The temperature was about 25°. Each lot of 0.1 g. powder was ground for 20 minutes. The powder so prepared showed a water content of 18.5%. It was then taken in small lots in the mortar, wet with conductivity water, ground until dry, and the resulting lumps were powdered. Analysis gave 21.0% water. Most of the particles were about 0.5μ in diameter, with a few 0.4μ . An increase in concentration of 4% was found.

Experiment 6.—It was observed, during examination of fine calcium sulfate particles under the microscope, that if water was used to wet the particles, a slight rubbing with the glass cover slip seemed to break them up into much smaller pieces. This suggested that the substance might be ground satisfactorily in the presence of water. Therefore, precipitated calcium sulfate crystals were wet with conductivity water and ground by hand in an agate mortar until dry. The resulting dry lumps were then ground until thoroughly powdered. The water content was 21.3%. The powder grains appeared very irregular in shape, and a large percentage of them were about 0.2μ , and some 0.3μ in diameter. The increase in concentration, as shown by conductivity measurements, was 12.3%.

Experiment 7.—Some of the ground powder used in Expt. 4, showing a water content of 21%, was heated at 100° for half an hour, until its water content had dropped to 15.5%. This powder when added to the saturated solution in the conductivity cell, showed an increase of 257% in concentration. There did not seem to be many smaller particles present after the heating than before, although, of course, there may have been a great deal of material too small to be visible in the microscope.

Discussion of Results

Examination of the results in Expts. 4, 5 and 6, shows that where precautions were taken to avoid dehydration, the increase in solubility due to the small size of the particles was not very great. In Expts. 4 and 5, where particles about 0.5μ in diameter were used, the average surface energy, calculated from Equation 5, taking i (that is, $1-\alpha+n\alpha$) as 1.56, was 356 ergs per sq. cm. Calculation by Jones' Equation 3 gave 352 (a difference of about 1%), while an error of only 0.01μ in the diameter measurement would make a difference of 2% in the value for surface energy. In the microscopic estimation of the size of particles, the probable error is much greater than 0.01μ . It is more nearly 0.1μ . Thus it is clear that the simplified Equation 5 is amply sufficient for present needs. It is also clear that very little reliance should be placed on our present knowledge of the surface energy of solids.

In Expt. 6, where the particles were estimated at 0.2μ in diameter, the calculated value of the surface energy was 385. The average for the two sizes, 0.5 and 0.2μ , is then about 370.

The question now arises as to why the above result differs from that of Hulett, who found a much larger increase in solubility. The possibility of slight dehydration is suggested by the fact that he does not specifically mention any moisture determination on his fine powder. Moreover, gypsum crystals are transparent, and have a low refractive index, and when finely powdered are difficult to observe sharply in the microscope, so that it is very uncertain how many particles too small to be visible might be present in the powder. When the material was wet almost until the last stage of grinding, as in our own Expts. 5 and 6, the probability of the occurrence of invisible small particles would be greatly lessened.

We wish to express our gratitude to the Grasselli Chemical Company for the fellowship grant under which this investigation was carried on.

Summary

- 1. A brief discussion is given of errors which appear in the literature in the calculation of surface energy and size of particles of calcium sulfate based on Hulett's data.
- 2. On the basis of the simplifying assumption that the degree of dissociation does not change with small changes of concentration, the van't Hoff factor, i, is introduced into the Ostwald-Freundlich equation, to replace the complicated correction formula of W. J. Jones.
- 3. Experimental data have been produced which show the great tendency of gypsum and precipitated calcium sulfate, CaSO₄.2H₂O, to become dehydrated during grinding, and the importance of this factor in relation to experiments on the solubility of finely powdered calcium sulfate.
- 4. Working with particles 0.2μ and 0.5μ in diameter a value of about 370 ergs/sq. cm. has been calculated for the surface energy of the dihydrate of calcium sulfate.

THE PHOTOGRAPHIC SENSITIVENESS OF SILVER IODIDE

By Frank E. E. Germann and Malcolm C. Hylan¹

RECEIVED MAY 14, 1923

Introduction

It has long been known that photographic emulsions containing silver iodide appear to be much less sensitive than do silver bromide emulsions. Should we expect this from purely theoretical considerations?

The photographic process may be roughly divided into two parts, (a) the photochemical effect of light upon the plate, and (b) rendering this effect visible by the process of development. It is with the first of these that we are concerned. There are at present several theories as to the exact nature of the action of light upon the plate, of which probably the most acceptable are the "nuclear" theory and the "sub-halide" theory.

Luther² claims that when a pure silver halide is exposed to light it undergoes reduclight

tion according to the equation, $2AgX \longrightarrow Ag_2X + X$. When the light is removed the dark sub-halide recombines with the free halogen according to the equation, $AgX + X \longrightarrow 2AgX$. Trivelli³ represents the photochemical action by a series of steps, with the formation of several sub-halides; in each step halogen is liberated. The original and final stages may be represented as follows, $Ag_nX_n \Longrightarrow nAg + \frac{n}{2}X_2$.

Lüppo-Cramer⁴ is an exponent of the nuclear theory which according to Lorenz⁵ may be expressed approximately by the equation, $nAgX + light \longrightarrow (n-1)AgX + Ag + X$. The silver particles liberated act as nuclei for the condensation of more silver during development.

It is to be noted that by each of these theories halogen is liberated, and from the law of mass action the reaction should proceed with greater velocity and more nearly to completion if this halogen were removed. So to represent the reaction more accurately, the equation (taking only the

first one given above) should be written, $2AgX + gelatin \longrightarrow Ag_2X + halogenated gelatin.$

The relative sensitivity of silver bromide and silver iodide must depend, in part at least, upon the speeds of their corresponding reactions. From the above equation we can see two factors which affect the speed of the reaction. The first of these is the stability of the silver halide. It is well known that bromine is more active than iodine, and has a greater affinity

for metals. This is evidenced by the fact that bromine will displace iodine from its salts. Silver and bromine, then, in silver bromide should be more strongly bound together than silver and iodine in silver iodide. Conversely, silver iodide should be more easily broken down by the action of light. This factor would seem to favor the greater speed or sensitiveness of silver iodide.

The second factor is the combining power of halogen and gelatin. Here, bromine, being the more active, would be expected to combine more readily. We shall show later that this is actually the case. This factor would seem to favor the greater speed of silver bromide. We have, then, our two factors opposed, and the relative speeds of bromide and iodide must depend, in part, upon the relative magnitudes of the two factors. Other factors, as we shall show, may also enter to affect the relative speeds of the two reactions.

J. A. Johnson⁶ has recently discovered a method for making iodide emulsions as sensitive as bromide emulsions. His patent is described as follows.

"For the production of high-speed print-out papers, plates, films, etc., coated with a light sensitive silver iodide emulsion. The emulsion may be produced by treating paper coated with silver chloride, bromide, or bromo-chloride emulsions with a soluble iodide, or by coating the paper directly with a gelatin or collodion emulsion, and sensitizing the emulsion after drying with a solution containing an organic sensitizer such as 'monomethylparaamidophenol sulfate' and an inorganic accelerator such as sodium sulfite. The sensitizing operation may be performed in daylight, since the sensitized emulsion does not become light sensitive until it is dried. The visible image produced on printing may be fixed by merely washing in water to remove the sensitizer; the unchanged silver iodide remains in the emulsion but is light insensitive."

The details of the above were communicated to the former of us before the patents were issued, and the desire was expressed that the theoretical side might be investigated. A careful study of the process should disclose the true causes of the lack of sensitiveness of ordinary silver iodide, and in what manner they may be overcome.

Experimental Part

Relative Combining Power of Bromine and Iodine with Gelatin.— Experiments to determine the relative combining power of bromine and iodine with gelatin were performed as follows.

A solution of iodine in potassium iodide was titrated against sodium thiosulfate solution. Five cc. of iodine solution was found to be equivalent to 2.4 cc. of thiosulfate solution. A concentrated solution of potassium iodide was then prepared and bromine water was run in, liberating iodine according to the reaction $Br + KI \longrightarrow KBr + I$. The liberated iodine was titrated against sodium thiosulfate. In this way 5 cc. of bromine was found to be equivalent to 3 cc. of thiosulfate solution, or 4 cc. of the bromine solution was equivalent to 5 cc. of the iodine solution. About 4 g. of gelatin was dis-

⁶ Johnson, C. A., 16, 3270 (1922).

solved in 150 cc. of distilled water and divided into 4 equal parts. To each of two of these 8 cc. of the bromine solution was added; to each of the other two 10 cc. of iodine solution was added. To each of the gelatin-bromine solutions was added as much crystalline potassium iodide as a spatula blade would hold and the liberated iodine was titrated with thiosulfate. In both cases only 0.3 cc. of the thiosulfate was required, indicating that about 95% of the bromine had combined with the gelatin. Two gelatiniodine solutions were then titrated with thiosulfate. In each case 5 cc. was required, indicating that practically none of the iodine had combined with the gelatin.

Experiments on Silver Iodide Emulsions.—Silver iodide emulsions were experimented upon directly in order to study their photosensitive characteristics and to determine the role played by Johnson's sensitizer. Excess of potassium iodide gave an emulsion that was not affected by light, was non-sensitive without treatment but was sensitized by bathing in Metol-sulfite solution, was not affected by light before sensitization and was accelerated by bathing in silver nitrate. Excess of silver nitrate, on the other hand, gave an emulsion that darkened on exposure to light, was sensitive without treatment, was unaffected by the Metol-sulfite solution, blackened when sensitized if previously exposed to light and was retarded by bathing in potassium iodide solution.

Johnson's emulsions contain an excess of potassium iodide. When they are washed for an hour in cold water an emulsion containing a large excess of potassium iodide is, after sensitizing, as fast as one containing much less potassium iodide, but when not so washed the greater the excess of potassium iodide the slower the paper. Furthermore, in this connection, small amounts of potassium iodide present in the developer bath act as very strong retarders or, if in sufficient amount, stop all action. It is well known that potassium bromide has a similar action in the development of bromide papers, although to a less degree.

Sensitizing Effect of Various Chemicals.—The effect of sensitizing with various developers was tried and a solution of monomethyl-p-amidophenol sulfate (Metol) with sodium sulfate was found to be the best. The sensitizing effect of several inorganic compounds was tried, a summary of which is given in Table I.

		TABLE I	
	SENSITIZING	Effect of Chemical Substance	\$S
Sensitized with	Exposure	Treatment	Results
Dil. H ₂ S	5-20 sec.	∫ Bathed in Metol, then in \	Water tenance
Dil. Na ₂ S ₂ O ₃	5–20 sec.	dil. alkaline Na₂SO₃ ∫	Fair image
$5\% \text{ Na}_2\text{S}_2\text{O}_3$	1 min.	Dil. alkaline Na ₂ SO ₃	
Dil. NaOH	5-15 min.	Bathed in Metol	
Dil. KOH	3-5 min.	Bathed in Metol	Faint image
5% Na ₂ SO ₃	3–5 min.	Metol, then alkaline sulfite	
5% NaHSO ₃	3-5 min.	Metol, then alkaline sulfite	
0 % Namous	5-5 mm.	Metol, then alkaline suinte	es .

Attention should be called to the fact that by sensitizing with 5% thiosulfate an image was obtained although no organic developer had been used at any stage of the process.

Properties of a "Neutral" Emulsion.—An emulsion having, within the limits of experimental error, no excess of either potassium iodide or silver nitrate was prepared as follows.

Ten g. of potassium iodide was dissolved in 100 cc. of distilled water (designated as Solution A). Ten g. of silver nitrate was dissolved in 40 cc. of distilled water and ammonium hydroxide added until the precipitate, at first formed, redissolved (designated as Solution B). Twenty-five cc. of Solution A was placed in a conductivity cell and the opposing resistance adjusted to give a reading near the center of the bridge. Solution B was added, 1 cc. at a time, the bridge reading being taken after each addition, until 20 cc. had been added. The experiment was then repeated, using 15 cc. of Solution A and adding 15 cc. of Solution B. Graphs were then made by plotting bridge readings against cc. added, and the volume of B corresponding to the break in the curve was determined. For the first titration 16.2 cc. of Solution B was equivalent to 25 cc. of Solution A. For the second titration 15.8 cc. of Solution B was equivalent to 25 cc. of Solution A. The average of the two is 16 cc.

From a buret, then, exactly 25 cc. of Solution A was run into a beaker, 5 g. of gelatin added, and the whole warmed until the gelatin had dissolved. Then exactly 16 cc. of Solution B was added.

The emulsion thus formed was painted on cards and dried. After about 4 hours, the cards, feeling dry to the touch, were exposed for 6 seconds, and bathed first in Metol, then in alkaline sulfite solution. A very good image was obtained.

Effect of Moisture.—Two or three days later some of these same cards were exposed and developed and the image found to be very much fainter than before. As the only difference between the cards at the two different times could be the amount of moisture in the emulsion, some of the cards were soaked in water for a minute and dried until they felt dry to the touch. Upon exposing and developing them very good images were again obtained.

To avoid the double bathing necessitated, in the case of iodide emulsions, by the use of the alkaline sulfite bath following bathing in the ordinary Metol developer, a developer was prepared by adding about 1% of sodium hydroxide to the Metol-sulfite solution, and was found to work well. Some of the cards covered with iodide emulsion, prepared according to Johnson, that is, with excess of potassium iodide, which had been coated several weeks previously, were exposed for 6 seconds and bathed for 10 minutes in this developer. A faint image was obtained. An iodide card covered with iodide emulsion prepared by converting a card covered with bromide emulsion, when exposed 6 seconds gave no image, even after 45 minutes' bathing in the developer. A "prepared" iodide card and a "converted" iodide card were then soaked in water for a minute and, after drying, exposed, the former for 6 seconds, the latter for 24 seconds. The former on 10 minutes' bathing in the developer gave a clear but light image: the latter, after 15 minutes' bathing, showed a faint trace of an image. The great difference between the "prepared" and "converted" cards is probably due to the fact that the latter have a surface coating of gelatin over the emulsion, put on to prevent abrasions, and to obtain results it is necessary to work down through this.

To compare the effect of moisture on bromide emulsions, a card covered with bromide emulsion was cut in two, and half soaked in water for a minute and dried. Both halves were then exposed for one second and bathed in developer for 15 seconds. At the end of that time the moistened card bore a good image, but the unmoistened card was still blank.

Comparison of Accelerating and Retarding Effects.—Three cards from the carefully prepared "neutral" emulsion, that is, having no excess of either potassium iodide or silver nitrate, were treated as follows. One was soaked in clear water, one in dil. potassium iodide solution, and one in dilute thiosulfate solution. After drying, each was exposed for 6 seconds and bathed in the alkaline developer for 15 minutes. The card treated with thiosulfate gave a very good image, the water-treated card a medium one, and the potassium iodide-treated card a poor one.

Discussion

The evidence of our experiments indicates that it is principally adsorbed potassium iodide which causes the apparent non-sensitiveness of silver iodide emulsions. That potassium iodide is adsorbed by silver iodide has been shown by Lottermosser and Rothe.⁷ Theoretically, we should not expect potassium iodide to have any greater retarding effect on silver iodide than potassium bromide on silver bromide. The fact that its retarding action is much greater can be easily explained on the basis of adsorption. To quote Lüppo-Cramer,⁸ "silver iodide in general possesses a higher degree of dispersity than the other silver halides." Consequently, a given weight of silver iodide has a much greater specific surface than the same weight of other silver halides, and therefore is capable of adsorbing much more soluble halide.

The experimental evidence in support of the above hypothesis may be briefly summarized as follows, remembering that when emulsions are spoken of as sensitive and non-sensitive we refer to the ability to produce an image after exposures of, at most, but few minutes duration, followed by bathing in the common photographic developers. (1) Emulsions containing no excess of potassium iodide are sensitive. (2) Emulsions containing any excess of potassium iodide are non-sensitive. (3) Considerable washing of an emulsion containing an excess of potassium iodide will not render it sensitive. (4) The presence of mere traces of potassium iodide in the developer bath retards or, if in sufficient amount, stops all action. (5) Bathing the emulsion in dilute solutions of compounds which

⁷ Lottermosser and Rothe, Z. physik. Chem., 62, 377 (1908).

⁸ Lüppo-Cramer, Kolloid Z., 30, 186 (1922).

would react with any adsorbed potassium iodide, thus removing it, renders the non-sensitive emulsion sensitive. This last point might easily be taken as due to the presence, in the emulsion, of reagents that combine with the liberated iodine. However, as they should react metathetically with any potassium iodide present long before exposure, it is likely that they function in both ways. In support of our hypothesis, and in harmony with (3) above, let us quote Trivelli and Sheppard⁹—"the separation (of adsorbed contaminants) by washing with pure solvent proceeds very slowly, adsorption being in most cases practically irreversible."

Our views find further confirmation in the work of Lüppo-Cramer¹⁰ who found that a partial transformation of silver bromide or silver chloride into silver iodide is associated with a great increase in sensitivity, but that a complete transformation into silver iodide results in a marked decrease in sensitivity. He says, in explaining this fact, "It seems probable that in the case of a complete transformation, the hard-to-be-avoided excess of soluble iodide, which is held stubbornly adsorbed by the silver iodide, is the cause of the reversal of sensitiveness."

Renwick,¹¹ too, attributes the loss in sensitivity on converting bromide plates into iodide, in part "to the great capacity of silver iodide for adsorbing soluble iodides, which would very much increase the difficulty of reducing it to metallic silver by alkaline development."

In the light of our hypothesis we can easily explain why, with the washed emulsions, it makes no difference how much potassium iodide is in excess, while with the unwashed emulsions the excess of potassium iodide is measured by the retardation of development. In the first case the free or unadsorbed potassium iodide is washed out and only the adsorbed remains, while in the latter case both adsorbed and unadsorbed potassium iodide are present, and there is, therefore, much more chance that some will be left in to retard development.

Another cause of the apparent non-sensitiveness of ordinary silver iodide emulsions is the absence of a sensitizer, gelatin not combining with iodine sufficiently to play that role. The experimental evidence supporting this conclusion is (1) iodine has practically no power for combining with gelatin; (2) sensitization is effected by addition of hydrogen sulfide, sodium thiosulfate, various sulfites, potassium hydroxide and sodium hydroxide to ordinary iodide emulsions, and is increased by their addition to "neutral" emulsions. Each of these compounds has the power of combining with iodine. The reactions are: $2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$; $H_2S + I_2 \longrightarrow 2HI + S$; $3I_2 + 6KOH \longrightarrow 5KI + KIO_3 + 2NaI$; $H_2S + I_3 \longrightarrow 2HI + S$; $3I_2 + 6KOH \longrightarrow 5KI + KIO_3 + 2NaI$

¹⁰ Lüppo-Cramer, Phot. Korr., 50, 561 (1913).

¹¹ Renwick, J. Soc. Chem. Ind., 39, 156T (1920).

 $3H_2O.^{12}$ Iodine reacts similarly with sodium hydroxide: $SO_3^+ + H_2O + I_2 \longrightarrow 2H^+ + 2I^+ + SO_4^=.^{13}$

The catalytic effect of moisture is also an important factor in the sensitization of silver iodide emulsions. This probably does not affect the relative speeds of iodide and bromide emulsions, as our experiments indicate that the effect on the one is as great as the effect on the other. However, other factors lower the sensitivity of iodide emulsions to such a degree that it is likely that moisture is an important factor in raising the photochemical action above the "threshold value" of developability.

We conclude then, that silver iodide emulsions are not strictly non-sensitive, but that, quoting Bolas, 14 "whether exposed or unexposed they are almost unaffected by such weak alkaline developers as are used in ordinary photographic practice;" that their low sensitivity is due primarily to the adsorption of potassium iodide, together with its strong retarding effect, and secondarily to the inability of gelatin to act as a sensitizer; and that if a sufficiently strongly alkaline developer is used, in spite of their low sensitivity, fair results may be obtained.

Johnson's process of sensitization does two things: (1) it removes adsorbed potassium iodide, and (2) it leaves organic developer in the emulsion to act as sensitizer, and later as developer. Hence, the emulsion being light sensitive and organic developer being present, all that is necessary to obtain an image is to expose it and then bathe it in dilute alkali to make the developer active. Bathing the sensitized paper in distilled water does not, as Johnson claims, desensitize it. It merely removes the unadsorbed developer dissolved in the emulsion, so that after exposure it is necessary to bathe the paper in organic developer before the alkali bath in order to bring out the image.

Summary

- 1. It is shown that from purely theoretical considerations it is impossible to predict whether or not silver iodide should be photographically more sensitive than silver bromide.
- 2. Johnson's method of sensitizing the apparently non-sensitive silver iodide emulsions is described.
- 3. Experiments have been performed to determine the nature of this process of sensitization.
- 4. It is shown that gelatin, which has a sensitizing effect in bromide emulsions, has practically no sensitizing effect in iodide emulsions.
- 5. Potassium iodide is shown to have a powerful retarding effect, emulsions containing an excess of this reagent being non-sensitive.
 - 6. A number of compounds, both organic and inorganic, which should
 - ¹² Thorpe, Longmans, 1912, vol. III, p. 152.

 - ¹⁴ Bolas, Brit. J. Phot., 68, 532 (1921).

react with potassium iodide or with iodine have been shown to have sensitizing effects.

- 7. An emulsion having no excess of silver nitrate or potassium iodide has been prepared and found to be sensitive.
- 8. Washing to remove the excess of potassium iodide does not make the regular iodide emulsion sensitive.
- 9. The amount of moisture present in the emulsion has been shown to have considerable effect on the sensitiveness.
- 10. In general, sensitization has been effected by treatment with a chemical which would react with potassium iodide to remove it, or remain in the emulsion to combine with any iodine liberated.
- 11. The "non-sensitive" emulsions have been found to be sensitive when a strongly alkaline developer was employed.
- 12. It is concluded that the apparent non-sensitiveness of silver iodide emulsions is due primarily to adsorbed potassium iodide, secondarily to the absence of a sensitizer, gelatin not playing that role; and that ordinary, apparently non-sensitive, silver iodide emulsions are truly sensitive when a sufficiently strongly alkaline developer is used.

THE CATALYTIC DECOMPOSITION OF HYDROGEN PEROXIDE BY FERRIC SALTS. II

By Van L. Bohnson and A. C. Robertson Received May 21, 1923

It has been known for some time that the decomposition of hydrogen peroxide is accelerated by the presence of iron salts in solution. The most recent quantitative investigations are those which were made by von Bertalan, by Duclaux, by Mummery, and by one of the writers of this paper. The purpose of the present paper is to present the results of subsequent experiments which necessitate certain modifications in the conclusions reached by these investigators. The work already reported was done with very dilute solutions of the catalyzing salts (up to 5 millimoles per liter). More concentrated solutions than this could not conveniently be used by the two first-named writers, owing to the difficulty of following the more rapid reactions by the cumbersome method of titrating samples with permanganate. On the other hand, the gasometric method offers an accurate means of measuring the rate of a reaction so rapid as to be entirely completed in 5 minutes.

Optical Evidence of an Intermediate Compound

Somewhat indirect evidence led to the suggestion in the previous paper⁴ that ferric acid (H₂FeO₄) is formed by the reaction between hydrogen peroxide and the iron salt, the ferric acid being subsequently reduced with the evolution of oxygen.

This hypothesis has been tested by photographing the absorption spectra of solutions of (1) ferric chloride alone, (2) barium ferrate dissolved in acetic acid, (3) potassium ferrate, and (4) mixtures of hydrogen peroxide and ferric chloride.⁵ The source of illumination and reference was the iron arc; a quartz spectrometer was used, the solutions being contained in a quartz absorption cell. Instead of varying the concentration or thickness of the solution, the times of exposure were increased logarithmically and a number of photographs taken on the same plate in the usual manner. The reaction mixtures were chilled in order to avoid too rapid disappearance of the supposed intermediate compound.

Some of the results are shown graphically in Fig. 1, the shaded portion of which represents the absorption bands, plotted on a uniform scale of wave lengths in Ångstrom units. A striking similarity between the bands for the two ferrates and for the reaction mixtures (R_1 and R_2) is obvious. On the other hand, a solution of ferric chloride of much greater than equivalent concentration shows no such characteristic bands in the yellow and green and is totally opaque to the violet. When hydrogen peroxide is added to the ferric chloride, transmission of violet lines takes place and absorption bands appear in the yellow and green. These results lead to the conclusion that the original hypothesis was correct; namely, that FeO₄ ions are present in the reaction mixture. The difference between R_1 and R_2 in the extreme violet suggests that the former reaction was

⁵ It was suggested by von Bertalan (Ref. 1) that an optical method might indicate the nature of the iron compound present.

nearer completion, there being more ferric chloride present, decreasing the transmission in that region. None of the solutions transmitted wave lengths shorter than 3500.

The Mechanism of the Reaction

It was suggested by von Bertalan that the reaction takes place in the following stages,

$$H_2O_2 + 2 \text{ Fe}^{+++} \longrightarrow 2 \text{ Fe}^{++} + 2 \text{ H}^+ + O_2$$
 (1)

$$H_2O_2 + 2 \text{ Fe}^{++} + 2 \text{ H}^+ \longrightarrow 2 H_2O + 2 \text{ Fe}^{+++}$$
 (2)

the sum of the two yielding the equation for the decomposition of hydrogen peroxide. It is possible to test the probability of these reactions taking place by means of the criterion suggested by Bray,⁶ that each of such a cycle of changes should be accompanied by a diminution of free energy. The standard free energy changes for Reactions 1 and 2 can be calculated, using the following values for the free energy of formation at 25°, in calories, given by Lewis and Randall: 7 H₂O₂ (aq.), -31,470; Fe⁺⁺⁺, -3120; Fe⁺⁺, -20,350; H₂O (1), -56,560; H⁺, 0; O₂ (g), 0.

From these data, ΔF_{298}° for Reaction 1 can be shown to be —2990 cals., while for Reaction 2 it is —47,190 cals. The difference in these values indicates that while ferrous ion may be oxidized to ferric ion by hydrogen peroxide in acid solution, it is not so probable that subsequent reduction will take place.

We have shown experimentally that ferrate ion is formed by the action of hydrogen peroxide on ferric salts. The following must therefore take place,

$$3 \text{ H}_2\text{O}_2 + 2 \text{ Fe}^{+++} + 2 \text{ H}_2\text{O} \longrightarrow 2 \text{ FeO}_4^{--} + 10 \text{ H}^+$$
 (3)

with subsequent reduction of the ferrate ion according to one or both of the following,

$$2 \text{ FeO}_4^{--} + 3 \text{ H}_2\text{O}_2 + 10 \text{ H}^+ \longrightarrow 2 \text{ Fe}^{+++} + 3 \text{ O}_2 + 8 \text{ H}_2\text{O}$$
 (4)

or

$$2 \text{ FeO}_4^{--} + 2 \text{ H}_2\text{O}_2 + 8 \text{ H}^+ \longrightarrow 2 \text{ Fe}^{++} + 3 \text{ O}_2 + 6 \text{ H}_2\text{O}$$
 (5)

with subsequent oxidation of the ferrous ion, or perhaps only decomposition of the ferrate ion by acid,

$$2 \text{ FeO}_4^{--} + 10 \text{ H}^+ \longrightarrow 2 \text{ Fe}^{+++} + 1^1/2 \text{ O}_2 + 5 \text{ H}_2\text{O}$$
 (6)

or

$$2 \text{ FeO}_4^{--} + 8 \text{ H}^+ \longrightarrow 2 \text{ Fe}^{++} + 2 \text{ O}_2 + 4 \text{ H}_2\text{O}$$
 (7)

Unfortunately no data are available for the free energy of formation of such substances as chromate, permanganate and ferrate ion. The only unknown value for calculating ΔF_{298}° for Reactions 3, 4, 5, 6 and 7 is that for FeO₄⁻⁻. By an application of the known data to Equations 3 and 4 we are led to the conclusion that F_{298}° must have a large negative

⁶ Bray, This Journal, 43, 1262 (1921); 45, 1251 (1923).

Lewis and Randall, "Thermodynamics," McGraw-Hill Book Co., 1923, p. 607.

value, probably between -106,885 cals. and -182,155 cals. Whatever its value, since it is the same in all the reactions, it can be readily shown that the diminution in free energy is greater in Reactions 4 and 5 than in 6 and 7. This is in accord with the experimental result reported in the previous paper that the reduction of the ferrate ion takes place extremely readily in the presence of hydrogen peroxide. It can also be shown that ΔF_{208}° is greater in Reaction 4 than in Reaction 5, and greater in 6 than in 7, which leads to the conclusion that ferrous ion is less likely to be formed. We have shown experimentally that it is not present after the reaction is completed. It is also true that during the reaction the addition of a little potassium ferricyanide yields a blue precipitate, but this, in the presence of hydrogen peroxide, is at best very questionable evidence of the presence of ferrous salt (as pointed out by Mummery³) since the ferricyanide may be changed to ferrocyanide and react with the ferric salt.

Experimental Study of the Rate of Reaction

This opportunity is taken of very briefly describing the method of determining the rate of reaction under various conditions. This method, which was used also in obtaining some data on promoter action to be discussed in a subsequent paper, was fundamentally the same as that used in earlier studies, 4,9 with some modifications and improvements. The materials used were the same as in the earlier studies. The reaction was allowed to take place in a specially designed flask supported in a thermostat by a shaking device, and the gas evolved was measured in a buret kept at the same temperature as the thermostat. The catalyst solution in the flask having been allowed to attain the temperature of the bath, a known amount of Perhydrol (30% hydrogen peroxide) was dropped into it, the shaking begun, and the volume of gas evolved was measured at known time intervals. In order to avoid difficulties due to hydrolysis of the catalysts, concentrated acidified solutions of the latter were prepared; these were diluted just before using, in such a manner that a known excess of free acid was present in the reaction mixture.

Calculations—Explanations of Tables

As previously noted, 4 the reaction, due to disturbing effects, is not strictly monomolecular, the values obtained for "velocity constants" varying

 8 Making the following arbitrary assumptions regarding F_{299}° for FeO₄--, ΔF_{298}° for the several reactions is as follows.

		CALORI	ES				
F ₂₉₈	Reaction 3	4	5	6	7		
-110,000	- 6,230	-144,310	-97,120	-69,040	-43,060		
-140,000	- 66,230	- 84,310	-37,120	- 9,040	+13,060		
-170,000	-126,230	- 24,310	+22,280	+50,960	+73,060		

The largest value estimated is thus shown to be too large, as FeO_4^{--} is rapidly reduced in acid solution, even when hydrogen peroxide is not present.

⁹ Bohnson, J. Phys. Chem., 24, 677 (1920).

slightly as the reaction proceeds. For the purpose, therefore, of comparing the rates of decomposition under different conditions, a velocity constant was calculated only over the second quarter of each reaction. A typical experiment, data for which are given in Table I, will serve to illustrate this method of calculation. In this table, as in all subsequent ones, the following abbreviations are used:

t = Time in minutes; T = temperature; N = normality of free acid present; $C_{\text{Fe}} = \text{concentration of iron salt in milligram-atoms of iron per liter}$; $C_{\text{HeO}_2} = \text{concentration of hydrogen peroxide in millimoles per liter}$.

TABLE I

DATA FOR TYPICAL EXPERIMENT

 $T = 30^{\circ}$ N = 0.076 $C_{\text{Fe}} = 10.0$ $C_{\text{H2O2}} = 130$

Total volume of gas evolved, 46.4 cc.; in second quarter of reaction, 11.6 to 23.2 cc.; time for second quarter of reaction, 18.7 min.; $K_R=94$

t...... 0 4 10 18 24 28 Cc. of O₂ evolved...... 0 4.9 8.2 12.7 18.0 21.5 23.6 46.4

The volume of oxygen evolved was carefully plotted against the time in minutes, and by interpolation from this curve the time was determined in which the second 25% of gas was evolved. The total volume of gas evolved was determined by a simultaneous experiment using the same concentration of hydrogen peroxide but a much larger concentration of catalyst, which caused the reaction in this experiment to reach completion in a very short time.

The usual expression for the monomolecular velocity constant, 0.4343 $K=(1/t)\log{(a/(a-x))}$, now becomes greatly simplified (since a is always 75%, and a-x always 50% of the total gas evolution) to $K_1=(1/t)\log{(3/2)}$, or $K_1=0.1761/t$. To avoid decimals, this constant is multiplied by 10^4 , and the value so obtained called K_R . This method of expressing the rate of the reaction proved to have several advantages: (1) a shorter time was required to complete a set of experiments; (2) routine calculation was reduced to a minimum; (3) much closer duplication of results was secured than by averaging values obtained by the usual method, and (4) the figures obtained represent comparable conditions. It will be noted that the results obtained are in effect a comparison of the times necessary for the completion of equal fractions of the reaction under various conditions, and that K_R is a measure of the relative rate of the reaction.

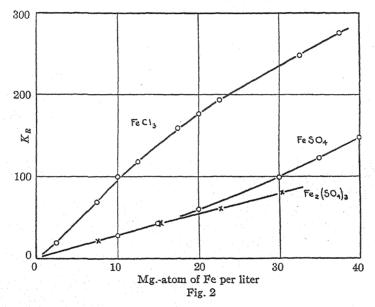

In order to save space, complete data for the remaining experiments are omitted, only summaries being given. The values reported for the velocity constants are supported by numerous other determinations, not given, of duplicate and intermediate values. There was no difficulty in checking within 3%.

Conditions of Experiment.—Unless otherwise noted, the concentration

of free acid was uniformly 0.076 N, that of the hydrogen peroxide 130 millimoles per liter, and the temperature 30°. All of von Bertalan's experiments were performed in complete darkness. This precaution having been found to be unnecessary, all of our experiments were performed in the diffused light of the laboratory.

The Effect of Ferrous Sulfate

It has already been shown¹ that the sulfates of both ferrous and ferric iron accelerate the decomposition of hydrogen peroxide, although less effectively than equivalent concentrations of either ferric chloride or nitrate. 4.10 It might be expected that equivalent concentrations of fer-

rous and ferric sulfates would have an identical effect; although von Bertalan worked with both these salts, his results do not shed much light on this particular problem. A more direct comparison of the effect of these two salts is possible by an examination of the data in Table II, which are shown graphically in Fig. 2.

Table II

Comparative Effects of Ferrous and Ferric Sulfates

		T_{\cdot}	= 30°	N = 0.076	C_1	$_{\rm H_{2}O_{2}}=1$	130	
	-Ferrous s	ulfate-				Ferri	sulfate-	
$C_{\mathbf{Fe}}$	K_R	$C_{\mathbf{Fe}}$	K_R		C_{Fe}	K_R	$C_{\mathbf{Fe}}$	K_R
10	28	30	99		7.6	21	30.4	81
15	43	35	123		15.2	43	60.8	156
20	60	40	148		22.8	60		

¹⁰ See also Fig. 2.

It will be noted that the curves for ferrous and ferric salts are coincident for concentrations of less than about 20 milligram-atoms of iron per liter, at which point the effect of the ferrous salt appears to become relatively and progressively greater. The reason for this divergence clearly lies in the fact that the ferrous sulfate is oxidized to ferric sulfate by the hydrogen peroxide, according to the equation, $2\text{FeSO}_4 + \text{H}_2\text{O}_2 + \text{H}_2\text{SO}_4 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + 2\text{H}_2\text{O}$, with a necessary decrease in the concentration of free sulfuric acid in the solution. The original concentration of acid being 0.076 N, it is evident that the oxidation of 20 millimoles or more of ferrous sulfate removes a relatively large proportion of the acid; since, as has been shown in other papers, free acid has a marked retarding effect on this catalysis, a decrease in its concentration causes an accelerated reaction. To this phenomenon is probably due the apparently greater catalytic effect of ferrous salt noted by Mummery.³

Von Bertalan claims to have found ferrous salt present after the completion of the reaction. This we did not find to be the case; on the contrary, when either ferrous or ferric salt is used as the catalyst, qualitative tests show it to be in the more highly oxidized form after the reaction is completed. During the progress of the reaction, the iron is present partly at least in a still higher state of oxidation. Quantitative measurements showed that in all cases in which ferrous sulfate was used as a catalyst, the volume of oxygen evolved was not equivalent to the amount of hydrogen peroxide used, a portion of the latter having been utilized in the oxidation of the iron. It is possible that a rapid method for the quantitative estimation of ferrous and ferric salts in the presence of each other might be based upon a measurement of the oxygen evolved from a given quantity of hydrogen peroxide.

It is incorrect, therefore, to speak of the catalytic effect of ferrous ion, which is oxidized instantaneously to ferric ion, and appears as such after the completion of the reaction; whatever accelerating effect it may have is due to the formation of the ferric salt. There seems to be need of further investigation of the action of hydrogen peroxide on certain alcohols and organic acids in the presence of ferric salts, which are reported to have no catalytic influence, ¹¹ while ferrous salts are said to have such an effect. Our preliminary experiments on this problem have led us to believe that ferric chloride at least is effective.

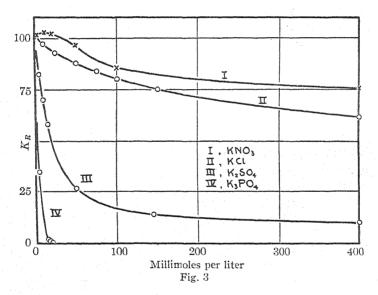

The Catalytic Effect of Non-ionized Salt

All previous work, as has been noted, was done with very dilute solutions of the iron salts. Von Bertalan, using only the sulfates, concluded that the rate of reaction was proportional to the concentration of iron ions.

¹¹ Fenton, J. Chem. Soc., **65**, 899 (1894). Fenton, Proc. Chem. Soc., **14**, 119 (1898). Doroschevski and Bardt, J. Russ. Phys. Chem. Soc., **46**, 754, 1669 (1914).

Duclaux, from an examination of our own previous work, concurred in this conclusion, even suggesting that this reaction is the best means of measuring the ionization and hydrolysis of iron salts, on the supposition that non-ionized salt is ineffective. This conclusion is supported by the facts that: (1) the effects of ferric chloride and nitrate in dilute solution are identical; (2) the suppression of ionization by added sodium or potassium salts is accompanied by a retardation of the reaction; (3) the addition of such a non-ionized salt as mercuric chloride had little or no effect, and (4) the products of hydrolysis had no effect.

On the other hand, the marked difference between the catalytic activities of ferric chloride and ferric sulfate is greater than might be expected from the different ionization of the two salts. This difference is more readily

explained by assuming that the molecular salt has an activity independent of that of the ions. Such an assumption would be in accord with a well-known hypothesis (the "dual theory" of catalysis) regarding catalytic processes, which has been discussed by a number of investigators.¹²

The curves shown in Fig. 3 (plotted from the data of Table III) represent the change in the catalytic activity of a constant concentration of ferric chloride (10 millimoles per liter) in the presence of increasing quantities of various neutral salts. One result of the addition of these salts is obviously the formation by metathesis of another ferric salt existing at least partly in the molecular state. In this connection a comparison of

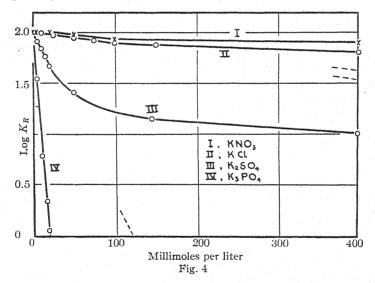

¹² See, among others, Acree, Am. Chem. J., 37, 410 (1907); 38, 258 (1907); 49, 353 (1913). Snethlage, Z. physik. Chem., 85, 255 (1913). Senter, J. Chem. Soc., 91, 467 (1907).

the curves indicates that the several molecular species vary in activity, the nitrate being most active. Another effect of the inhibiting salt would

Table III

		1880	60				

be the suppression of the ionization of the iron salt; however, the addition of a quantity of neutral salt 40 times as great as that of the ferric chloride

present is insufficient to inhibit the reaction completely. In the case of potassium nitrate, the addition of 188 times as much decreased the velocity constant only to 60, which represents a greater rate than would be expected on the supposition that iron ions alone are active. The rapid decrease in activity when potassium phosphate is added may be due to the removal of iron as a complex ferric-phosphate ion.¹³

It may be concluded, therefore, that in this reaction both the ions and the molecules are catalytically active.

¹³ Weinland and Ensgraber, Z. anorg. Chem., 84, 340 (1913).

In Fig. 4 the same data are plotted with the logarithms of K_R as ordinates. An examination of the curves thus obtained shows that they begin as straight lines, indicating that the first result of the addition of neutral salt is an exponential function of the concentration. The curve changes direction and proceeds again as a straight line with a different slope than formerly. A second effect is thus indicated, of smaller magnitude than the first one. These facts admit of two interpretations.

- 1. The first segment in the curve for all salts but potassium chloride may represent the metathetical reaction, while the second represents the suppression of the ionization of the newly formed salt. This hypothesis fails to explain the marked break¹⁵ in the potassium chloride curve. The single effect of the potassium phosphate curve is explained by the formation of a complex ion.
- 2. The two segments may represent two molecular forms of somewhat differing activity. The reason for such a difference is not clear, but the suggestion, which proves useful in a study of the accelerating effect of copper salts, will be discussed in a subsequent paper.

The Temperature Coefficient

In Table IV are shown the results of a number of experiments to determine the temperature coefficient of the reaction in the presence of

			I Al	31/14 T A			
Eff	ECT OF	Catalyst a	ND ACID	on the T	EMPERATU	re Coeff	ICIENT

		Mean	value fo	E = 23	960 cals.		

different concentrations of catalyst and of acid. The results seem to be somewhat in accord with the assumption of the radiation hypothesis that "any agency which increases the reaction velocity diminishes the temperature coefficient," 16 although the decrease in values with increasing con-

¹⁴ These facts are more marked when all of our data are plotted on a large scale.

¹⁵ When copper salts are present in addition (markedly increasing the reaction rate), there is no break in the potassium chloride curve.

¹⁶ Lewis, J. Chem. Soc., 109, 796 (1916).

centration of catalyst is not particularly marked. It may be noted that the change of coefficient with temperature is not so great with sulfate as with chloride, the results for the former agreeing substantially with those of von Bertalan, who found $K_{40}/K_{30}=3.2$ and $K_{30}/K_{20}=3.3$.

In the columns E_1 and E_2 are shown the "critical increments" of the reaction according to the radiation hypothesis, calculated from the expression $\frac{d \log K}{dT} = \frac{E}{RT^2}$. The mean value of the critical increment is 23,960 cals. per mole of hydrogen peroxide decomposed; this, when substituted in the expression $E = Nh\nu$ gives 2.5×10^{14} for the frequency of the active radiation, the wave length of which would therefore be 1.2×10^{-4} cm. $= 1.2 \mu$.

Summary

- 1. This paper is a continuation of a former study of the catalytic decomposition of hydrogen peroxide by ferric salts. The existence of an intermediate compound, H₂FeO₄, previously suggested, has been confirmed by a spectroscopic examination of the reaction mixture.
- 2. The free energy of formation of ferrate ion, FeO_4^{--} , is shown to be in the neighborhood of -140,000 cals. Free-energy relationships show that the ferrous-ferric ion intermediate reactions postulated by von Bertalan are improbable.
- 3. The catalytic effect of ferrous salts is shown to be due solely to the fact that they are oxidized first to ferric salts.
- 4. The molecules of ferric salt, as well as the ions, appear to exert catalytic activity. It is possible that there are two molecular forms of differing activity.
- 5. The temperature coefficient of the reaction shows the "critical increment" of the reaction to be 23,960 cals., the frequency of the active radiation 2.5×10^{14} , and its wave length 1.2μ .

A WATER-JACKETED HYDROGEN ELECTRODE

By Henry S. Simms Received May 21, 1923

A hydrogen electrode cell has been designed to give rapid and accurate results and at the same time offer greater convenience in manipulation when working with certain fluids, than other types of cells. The results have been sufficiently satisfactory to warrant publication of a description of the cell.

¹⁷ For the methods of these calculations, see among others, Daniels and Johnston, This Journal, 43, 53, 72 (1921).

Description of Cell

This cell is kept at constant temperature by means of a water jacket through which water from a thermostatic bath is circulated. It has a 3-bore, 4-way stopcock which performs all the functions required. This stopcock is bored as shown in Fig. 1. The three bores do not intersect. Bore c is used in both Position III and Position IV. In order that both ends of Bore c may coincide with the opening of the arm for the salt bridge,

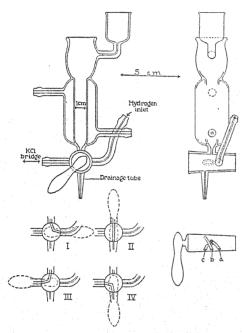

Fig. 1.—The water-jacketed hydrogen electrode cell. In Position I, Bore a connects the source of hydrogen with the cell; in Position II, Bore b connects the cell with the drainage tube; in Position III, Bore c connects the cell with the salt bridge; in Position IV, Bore c connects the salt bridge with the drainage tube. Order of manipulation: I, II, IV, III

this opening of the arm must be elliptical in shape. The cell may be constructed of either Pyrex or ordinary glass.

The Platinum Electrode is a spiral of platinized platinum wire sealed into a glass tube passing through a rubber stopper to the bottom of the cell. The tube contains mercury in order to make contact. stopper has a supplementary hole for the escape of hydrogen. Readings are taken with the electrode entirely immersed. The spiral serves, furthermore, to break up the bubbles of hydrogen, thus promoting rapid saturation. The electrodes are frequently changed and re-platinized. A fresh electrode must be saturated for a much longer period before the first reading is made. When not in use, the cell is kept filled with distilled water.

The Calomel Cell is constructed with a water jacket and has a platinum wire sealed into

the bottom and a mercury contact. In it are placed mercury, calomel and mercury, and a solution saturated with both potassium chloride and calomel. It is filled to the top and when the stopper is introduced the excess solution is forced out of the tube (which contains a loose plug of cotton), thus eliminating all air bubbles.

The Salt Bridge is "closed," that is, not open to the atmosphere's pressure. When the liquid junction is formed there can be no flow of liquid. Saturated potassium chloride solution is used to eliminate liquid junction

potential and, for convenience, is colored with α -azurine G. A reservoir (D) of this solution is kept at constant level by means of a glass tube connected with an inverted bottle of potassium chloride solution on a shelf above the apparatus, and is connected to the bridge by means of a stop-cock (E) which is kept closed by an elastic band attached to a glass hook fused to the stopcock handle. One liter of potassium chloride solution will serve as a supply for a year.

The Hydrogen, which is supplied from a tank with a reducing valve, is passed through water and then through a coil in the constant-temperature bath, from which it is brought to the electrode by means of Tube J. The

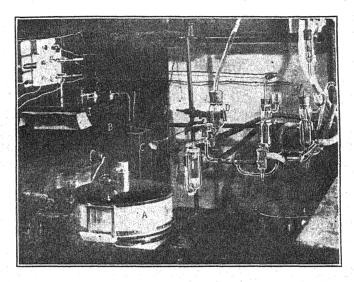

Fig. 2.—Hydrogen-ion apparatus. A. Potentiometer. B. Galvanometer. C. Storage battery, single cell. D. Constant level reservoir of saturated potassium chloride solution. E. Automatic nipple for distilled water supply

pressure of the hydrogen is regulated to about 6-7 mm. of mercury. This gives an even flow of small bubbles when the stopcock (in Position I) is partly opened.

Water Circulation from the bath through the cells is accomplished by means of an "air lift" which is merely a siphon system through the cells into which air is injected to raise the water back up to the bath. It is not essential for the functioning of the air lift that the bath be at a higher level than the cells. If the bath were on the same level as (or even below) the cells, the water after passing through them could be carried down to

the floor and then raised to the bath by means of the air lift, thus circulating the water.

Manipulation

The hydrogen electrode cell has but a single stopcock which performs the following functions. First, in Position I, it allows hydrogen to be bubbled through the apparatus (for three minutes). Second, in Position II, it permits a few drops of solution to drain, and thus remove all bubbles of hydrogen.1 Third, it is swung around (to the left) to Position IV, connecting the salt bridge with the drainage tube. Here no liquid can flow until Stopcock E is opened. Hence the stopcock of the cell is left open in Position IV while the operator reaches with the same hand to open Stopcock E, permitting a few drops of potassium chloride solution to drain. Thereafter it is necessary merely to release the Stopcock E, since it closes automatically. This procedure has filled Bore c of the cell stopcock with potassium chloride solution. Fourth, it is then turned to Position III, thus forming the liquid junction, and a reading is taken. If another reading is desired, the stopcock is turned to Position II, where a few drops of solution are allowed to drain, and then turned to Position I, where the saturation with hydrogen is continued.

Discussion

This cell has the following advantages.

- 1. Its temperature may be accurately controlled without interfering with its manipulation. It may be more conveniently handled than is the case with cells placed in an air or oil thermostat.
- 2. The temperature of the cell is maintained with such constancy that a solution which is much colder or much warmer than the cell will be brought to the desired temperature during the three minutes required for saturation. Thus, a solution may be taken from the refrigerator and introduced directly into the cell without being previously warmed.
- 3. One stopcock performs all the functions required, thus preventing accidental passage of gas into the salt bridge or of potassium chloride solution into the cell.
- 4. The closed bridge prevents mechanical agitation when the liquid junction is formed.
- 5. The liquid junction is only 6 mm. from the platinum electrode, thus permitting accurate readings even with solutions of low conductivity.
 - 6. One to two cc. of solution is sufficient for 2 to 6 consecutive readings. Accuracy.—Bubbling with hydrogen for three minutes gives readings
- ¹ In case the drainage of the solution (in Position II) is stopped by bubbles, the hole in the rubber stopper is closed with the forefinger of the left hand, while the fleshy portion of the right thumb is gently pressed on the filling cup of the cell. The pressure created will start the flow of liquid.

which do not change more than 0.1 to 0.2 millivolt even after two hours' bubbling. Readings are reproducible to $0.01~P\pi$.

The fact that the whole system is not at the same temperature should produce no appreciable error, since the liquid junction is at practically the same temperature as the electrodes and no potential can be produced by temperature variations in the bridge.

The "open stopcock" junction is subject to the usual errors.

Summary

A simple water-jacketed hydrogen electrode cell of the bubbling type is described which is accurately maintained at constant temperature with water from a bath, circulated by means of an air lift.

It gives accurate readings reproducible to 0.01 PH with 1 or 2 cc. of solution after three minutes' saturation with hydrogen, even with solutions of low conductivity.

It has a single stopcock which performs separately the following functions: It permits (1) bubbling of hydrogen gas through the solution; (2) drainage of solution; (3) drainage of potassium chloride solution from the salt bridge; (4) formation of liquid junction.

THE FREE ENERGY OF MERCURIDES

By Roscoe H. Gerke Received May 26, 1923

Alloys and metallic compounds are important classes of substances for which there are few free-energy data. It is the purpose of this paper to collect available data on metallic compounds and solid solutions containing mercury, and incidentally point out that the method of calculating these quantities involves the use of partial molal free energy. Hitherto, the concept of partial molal free energy has not been used to split up the free energy of formation of a compound from its constituent elements into two parts, as has been done in this paper. In the case of the mercurides and other metallic compounds, it will be seen that the free energy of formation of the compound from its elements is equal to the sum of the separate free-energy changes which the elements undergo in the formation of the compound.

In the case of sodium mercuride, NaHg₅, the partial molal free energy \overline{F}_2 , of the sodium in the compound is measured by the electromotive force of the galvanic cell, Na(s) | Na⁺ | Na in Hg + NaHg₅(s). The chemical equa-

¹ The notation employed is that of Lewis and Randall, This Journal, 43, 233 (1921).

tions which represent the change of state attending the passage of electricity through the cell are as follows.

Equation 3 represents the sum of Equations 1b, 2a and 2b. It represents the change in state in the formation of one gram-atom of sodium in the compound and the corresponding change of free energy is equal to the partial molal free energy of one gram-atom of sodium, \overline{F}_2 , in the compound, since the change of free energy in an equilibrium process is zero and the free energy of an element in its standard state is taken as zero.

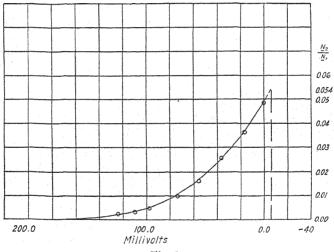

Fig. 1

If the free energy of dilution of the sodium in the mercury amalgam has been measured at various dilutions, then the partial molal free energy of the mercury, \overline{F}_1 , in the compound may be determined with the aid of the Gibbs equation, $d\overline{F}_1 = -\frac{N_2}{N_1}d\overline{F}_2$, which when integrated takes the form, $\overline{F}_1 - F_{(Hgl)} = \overline{F}_1 = +nf \int \frac{N_2}{N_1}dE$, where E is the electromotive force of galvanic cells similar to the one previously described, with different concentrations of electropositive metal in the dilute amalgams.

The integration is most conveniently carried out by plotting as ordinates the electromotive force and as abscissas the corresponding ratio, N_2/N_1 of the mole fractions of the constituents of the liquid amalgams. In Fig. 1

the data² for dil. sodium amalgams are plotted. A small extrapolation to the saturated amalgam, $N_2/N_1 = 0.054$, is indicated by the dotted line. The limits of the integration for N_2/N_1 are 0 and 0.054, respectively, and for E they are $+\infty$ and -6 millivolts, respectively. The area under the curve multiplied by the proper factor to convert to calories is equal to the change in free energy when one gram-atom of liquid mercury reacts to form one gram-atom of mercury in the liquid amalgam, which in turn is equal to the partial molal free energy of one mole of mercury in the compound, since the free energy of the liquid mercury is zero.

The free energy of sodium mercuride was calculated as follows,

$$Na(s) = Na \text{ (in NaHg5); } \Delta F = \overline{F}_2$$
 (4)

$$5 \text{Hg(I)} = 5 \text{Hg (in NaHg5)}; \Delta F = 5 \overline{F}_1$$
 (5)

$$Na(s) + 5Hg(1) = NaHg_5(s); \Delta F^{\circ} = \overline{F}_2 + 5\overline{F}_1$$
 (6)

In Table I are shown the free energies of formation of the mercurides of sodium and lead.

Table I
Free Energy of Formation of Mercurides of Sodium and Lead

N ₂ (sat.) °C.	E.m.f.	$\overline{\mathbf{F}}_{2}$	$\overline{\mathbf{F}}_{1}$	ΔF°	Compound
0.054^a 25	0.7821 ^b -	18,046	-61°	-18,351	$NaHg_5^d$
0.017 30	0.0058 ^f	- 134	-12^{g}	- 280	Pb_2Hg^e

In Table I, a corresponds to References 3, 6; b to 2, 3, 4, 5; c to 2; d to 6; e to 7; f to 8; g to 9.

The mole fraction, N_2 (sat.), of the more electropositive metal in the liquid amalgam saturated with the compound is listed in Col. 1; the centigrade temperature in Col. 2; the electromotive force in volts of the galvanic cell, corresponding to Equation 1, in Col. 3; the partial molal free energy, \overline{F}_2 , in calories of one gram-atom of the more electropositive metal in the compound in Col. 4; the partial molal free energy \overline{F}_1 in calories of one gram-atom of mercury in the compound, in Col. 5; and finally the free energy of formation ΔF° , of one mole of the compound in Col. 6. (The footnotes refer to the sources from which the data were taken.)

In Table II are collected the partial molal free energies of metals in the mercurides of lithium, potassium and rubidium. Since the free energies of dilution of these electropositive metals in mercury amalgams have not been measured, the partial molal free energy, 10 \overline{F}_1 , of the mercury was

- ⁹ Richards and Garrod-Thomas, Z. physik. Chem., 72, 165 (1910).
- 10 It is nearer to the truth to make this assumption than to calculate this quantity from the equation $\vec{F}_1 = RT \ln N_1$ assuming that Raoult's law is valid, since this calculation gives -30 calories as the value of the partial molal free energy of one mole of mercury in sodium mercuride, instead of the value -61 calories in Table I Since the

assumed to be the same as that in the case of sodium. Also, the liquid amalgams in the galvanic cells were not saturated with the solid compounds, as in the case of the sodium and lead mercurides. The small correction could be calculated and subtracted from the measured values, but since the measured values for the dilute amalgams are of such high precision, it may be well to insert them in the table as they appear in the literature.

Table II

Partial Molal Free Energy of Alkali Metal Mercurides at 25°

N ₂ (sat.)	N_2 (dil.)	E.m.f. (dil.)	F ₂	$\overline{\mathbf{F}}_{1}$	Mercuride
0.02^{11}	0.0087	0.9502^{12}	-21,900	(-61)	${ m LiHg_3}^6$
.0313	.011	1.048114	-24,200	(-61)	$\mathrm{KHg_{12}}^{6}$
.0315	.0054	1.0745^{16}	-24,800	(-61)	$RbHg_{12}^{6}$

In Table II are listed, respectively, N_2 sat., the mole fraction of the electropositive metal in the saturated amalgam; N_2 dil., the composition of the dil. amalgam actually employed in the cells; e.m.f. dil., the electromotive force, in volts, of the cell, the electrodes of which are solid electropositive metal and dil. amalgam; \overline{F}_2 and \overline{F}_1 are the approximate partial molal free energies in calories of one gram-atom of the electropositive-constituent and of one gram-atom of mercury in the compound, respectively.

TABLE III

PARTIAL MOLAL FREE ENERGY OF METALS AND OF MERCURY IN MIXED CRYSTALS

Na (sat.)	°C.	E.m.f.	$\overline{\mathbf{F}}_{2}$	$\overline{\mathbf{F}}_{\mathbf{i}}$	Mixed crystals
0.07	25	0.0047 ^h	-215	- 35°	Zn in Hg
10^{i}	25	.0505 ^k	-2330	- 77 ¹	Cd in Hg
.43**	20	$.0022^{n}$	- 51	-523°	Tl in Hg

In Table III, g corresponds to references 17, 18, 19; h to 20, 21; i to 22, 23, 24; j to 19; k to 19, 20, 22, 25, 26; l to 24, 27; m to 28; n to 28, 29, 8; o to 1, 28.

mole fraction, N_1 , of the mercury in these cases in Table II is greater than that in the case of sodium mercuride in Table I, the partial molar free energies, \overline{F}_1 , of one mole of mercury in Table II are certainly not greater than, and in all probability are less than the value, -61 calories.

In Table III are listed precise partial molal free energies of one gramatom of the constituents of mixed crystals, in order to compare them with the partial molal free energy of the constituents of compounds.

Discussion

The conventions have been such that the free energy of formation, $\Delta F^0 = -18,351$ calories, means that there has been a decrease at 25° and 1 atm. of free energy attending the formation of one mole of NaHg₅ from one atom of sodium and 5 atoms of mercury. This decrease has been divided between the decrease for the sodium and the mercury respectively, such that \overline{F}_2 equals -18,046 calories and \overline{F}_1 equals 61 calories per atom. It is to be noted that the more electropositive the metal, the greater is the free-energy change, except in the case of lithium.

The most striking and unexpected conclusion which can be drawn from these data, is that the mercury does not greatly change in free energy, when it enters into chemical combination with a more electropositive metal. In other words, the vapor pressure of pure liquid mercury is only very slightly greater than the partial pressure of mercury from an amalgam saturated with a mercuride. On the other hand, the electropositive metal decreases in free energy more than the mercury in the formation of the compounds. In the case of the mixed crystals, thallium is an exception, which possibly may be due to the fact that it is so close to mercury in the periodic table of the elements.

Although the free energy of other metallic compounds and also compounds of the type represented by iodine chloride can be calculated by the above method, it does not seem feasible to make similar measurements for a simple compound such as sodium chloride, since it is not possible to have solid sodium chloride in equilibrium with its solution of sodium in liquid chlorine.

In conclusion, it may be stated that, if mercury reacts with a more electropositive metal to form a mercuride, the change in free energy for the mercury is small compared with that of the more electropositive metal.

The author wishes to express his appreciation for the helpful criticism of Dr. L. J. Gillespie and Dr. E. B. Millard.

Summary

- 1. The partial molal free energy of the electropositive atom in a mercuride or a mixed crystal containing mercury has been calculated from the measured value of the electromotive force of a galvanic cell, the electrodes of which consist of the electropositive metal and the liquid amalgam saturated with the mercuride or mixed crystal.
- 2. The values for the partial molal free energies of rubidium, potassium, lithium, sodium and lead in their mercurides have been found to be -24,800, -24,200, -21,900, -18,046 and -134 calories, respectively.

- 3. The partial molal free energy of mercury in some mercurides has been calculated from the measured values of the electromotive force of amalgam concentration cells.
- 4. The values for the partial molal free energy of mercury in sodium and lead mercurides were found to be —61 and —12 calories, respectively.
- 5. The free energies of formation of sodium and lead mercurides are —18,351 and —280 calories, respectively.
- 6. The partial molal free energies of the constituents of mixed crystals of zinc-mercury, cadmium-mercury and thallium-mercury crystals have been tabulated.
- 7. With the exception of thallium, it has been found in the case of the mercurides and the mixed crystals studied, that the change in free energy has been greater for the electropositive metals than for mercury.

PROMOTER ACTION IN HOMOGENEOUS CATALYSIS. I. COPPER SALTS AS PROMOTERS IN THE IRON SALT CATALYSIS OF HYDROGEN PEROXIDE

By Van L. Bohnson and A. C. Robertson Received June 11, 1923

The investigation described in this paper was an outgrowth of an earlier study^{1,2} of the catalytic decomposition of hydrogen peroxide, during which it was noted that the rate of evolution of oxygen in the presence of a mixture of iron and copper salts is much more rapid than the rate which may be calculated on the assumption that each salt acts independently. This phenomenon is analogous to what has been known in cases of heterogeneous catalysis as "promoter action." The latter designation, first used in the patents of the Badische Anilin und Soda Fabrik, might well include, according to Pease and Taylor,3 all those cases in which a mixture of two or more substances is capable of producing a greater catalytic effect than can be accounted for on the assumption that each substance in the mixture acts independently. So defined, the term is applicable not only to cases of heterogeneous catalysis, to which it was first applied, but also to homogeneous catalysis, and in this sense it is used in this paper; such a use is no intimation that the mechanism of reaction in the two different systems is the same.

The known examples of promoter action have been reviewed and classified by Pease and Taylor,³ and therefore will not be described here. Ex-

¹ Bohnson, J. Phys. Chem., 25, 19 (1921).

² Bohnson and Robertson, This Journal, 45, 2493 (1923).

³ Pease and Taylor, J. Phys. Chem., 24, 241 (1920).

amples in the field of homogeneous catalysis are relatively few in number, the one best known being the effect of neutral salts in accelerating the acid-catalyzed hydrolysis of esters. Two reactions which are of interest in connection with the present study are the oxidation of potassium iodide by potassium persulfate, and the reaction between hydrogen peroxide and hydriodic acid; in both of these cases the reaction was "promoted" by the action of copper salts in the presence of iron salts.

Purpose and Method

In an attempt to outline in a preliminary way the mechanism of promotion, this paper will be devoted to a discussion of the factors involved in the accelerating effect of copper salts upon the iron-salt catalysis of hydrogen peroxide in acid solution. Further papers will deal with promoter action in other homogeneous reactions, such as the activation of chromic acid and its salts (catalyzing the decomposition of hydrogen peroxide) by certain cations, a reaction which is now being studied in this Laboratory.

It has been suggested by Pease and Taylor³ that a distinction be made between simple "activation" of one catalyst by another substance not itself a catalyst for the reaction in question, and "co-activation," in which the catalytic effect of each active substance is increased by their joint presence. From this point of view, it is possible with the reaction in question that (1) the copper salt may be activated by the iron salt, (2) the iron may be activated by the copper, or (3) the two may activate each other. It is not always easy to decide among such hypotheses, but a determination of the promotion effect in the presence of various amounts of iron or copper may enable us to exclude certain of them, on the reasonable expectation that in any activation of one substance by another there is a limit to the accelerating effect of the primary catalyst when all the catalytic material has been "activated."

The method used for measuring the rate of reaction has been previously described.² The results obtained are merely summarized as in the previous paper, and are supported by numerous duplicates and intermediate values. In the tables the following abbreviations are used: T, temperature; N, normality of free acid present; $C_{\rm Fe}$, concentration of iron salt in milligram-atoms of iron per liter; $C_{\rm Cu}$, concentration of copper salt in milligram-atoms of copper per liter; K_R , the relative rate of reaction (see p. 2497 of preceding paper). In all experiments, unless otherwise noted, the concentration of free acid was 0.076 N, that of the hydrogen peroxide 130 millimoles per liter, and the temperature 30°. All experiments were performed in the diffused light of the laboratory, after it was

⁴ Price, Z. phys. Chem., 27, 499 (1893).

⁵ Brode, ibid., 37, 257 (1908).

found that those performed in darkness were not retarded either in the presence of iron alone or of iron and copper together.

Preliminary Experiments

Ferric chloride in solution exerts an energetic decomposing effect on hydrogen peroxide even in the presence of hydrochloric acid, which retards the catalysis materially. Ferric sulfate in sulfuric acid solution has a marked effect, less than that of the chloride. On the other hand, much larger quantities of cupric chloride, either in acid or in neutral solution, have very little noticeable effect. In fact, the salts of few other metals act as vigorously as the iron salts. When, however, small amounts of copper salt are mixed with the iron salt, the rate of reaction is very markedly increased. This effect seems to be peculiar to copper compounds; nickel, cadmium, mercury, barium, lead, cobalt, zinc, tin, and magnesium salts appear to retard rather than accelerate the reaction. In sulfate systems silver appears to have a very slight accelerating effect.

Effect of a Fixed Concentration of Copper in the Presence of Variable Iron Concentration

Fig. 1 shows graphically the relation between the rates of reaction caused by each salt alone and by mixtures containing various fixed concentrations

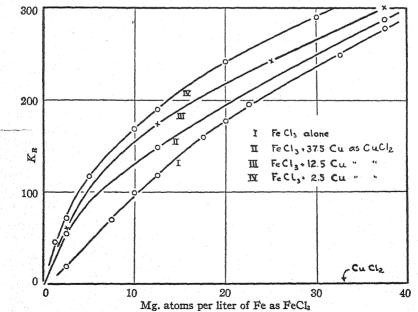

Fig. 1.—Effect on reaction rate of fixed copper with varying iron concentration of copper salt and varying concentrations of iron salt; the data for the curves are given in Tables I and II. In all these experiments the chlorides were used; the effect in sulfate systems will be considered later.

12.5	190			37.5	300	• •	,

The curve for cupric chloride alone may scarcely be distinguished from the horizontal axis; therefore, on the assumption that the joint effect of iron and copper salts is purely additive, the curve for this joint effect should coincide with the curve for ferric chloride alone. It will be noted, however, that the presence of only a small amount of copper salt causes a marked acceleration. A large concentration of copper, as shown by Curves II and III, has a smaller effect; it is therefore evident that some concentration of copper in the vicinity of 2.5 milligram-atoms per liter is more effective than any other. From these results we may exclude the hypothesis that the copper salt is activated by the iron.

Effect of a Varying Concentration of Copper with a Fixed Concentration of Iron

That there is a maximum effective concentration of copper salt is better illustrated by the results shown in Figs. 2 and 3 (Tables III and IV). The curves represent the variation in the rate of reaction caused by varying concentration of copper salt in the presence of different fixed concentrations of iron salt. A relatively minute amount of copper has a marked effect, but in each case a maximum rate of reaction is obtained with a concentration of only 1 milligram-atom per liter. Beyond this point, the rate continually decreases with the addition of more copper, an effect which is quite analogous to that caused by the addition of sodium chloride. The maximum effective concentration of copper appears to be independent of the concentration of iron salt.

That the effect is common to both chloride and sulfate systems is evident; the maximum concentration of copper in each case is of the same order of magnitude, although ferric sulfate is a much less active catalyst than ferric chloride. It is also evident (Curve II, Fig. 3, and last column, Table IV) that the maximum effective concentration of copper is not altered by a large decrease in the concentration of the free acid present. These results lead to the conclusion that the iron salt is activated by the presence of a copper salt.

Conditions Affecting the Extent of Promotion

Promotion Factors.—It has been shown that for any given concentration of iron, a maximum rate of reaction is obtained with approximately the same absolute concentration of copper in all cases. By dividing the maximum rate by the normal rate for the given concentration of iron, a ratio is obtained which may conveniently be termed the "promotion

factor;" this factor represents the extent of promotion under given conditions.

Effect of Concentration of Catalyst.—The promotion factors for different concentrations of iron salt can be calculated from the values obtained

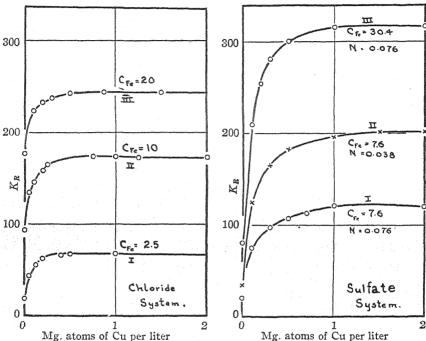

Fig. 2.—Effect on reaction rate of fixed iron with varying copper concentration iron with varying copper concentration

by interpolation from the curves of Fig. 1 and Fig. 4. The latter, for which the data are shown in Table V, represents the promotion process when sulfates of iron and copper are used (in the presence of free sulfuric acid).

Table V
Effect of a Varying Concentration of Ferric Sulfate

$C_{ extsf{Fe}}$	3.8	7.6	15.2	22.8	30.4	38.0	60.8
K_R : no Cu		21	43	60	81		156
K_R : $C_{Cu} = 1.0$	72.5		200	263	320	366	

TABLE VI

VARIATION OF PROMOTION FACTORS WITH CONCENTRATION OF IRON SALT

C_{Fe}	Promotion Chlorides	n factors Sulfates	C_{Fe}	Promotion Chlorides	n factors Sulfates
1	5.0	8.0	15	1.5	4.9
2	3.6	7.0	20	1.3	4.6
4	2.7	6.7	25	1.2	4.2
.7	2.1	6.0	30	1.2	4.0
10	1.7	5.6	40	1.17	••

In this case, as is shown also in the last column of Table VI, the promotion factor is much larger than in the chloride system, although the normal rate is less.

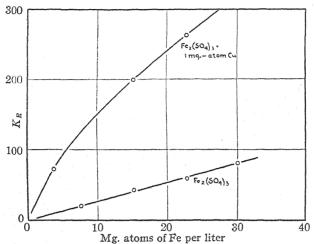

Fig. 4.—Effect on reaction rate of fixed copper with varying iron concentration

In both systems the promotion factor decreases as the concentration of iron salt increases, probably approaching 1 as a limiting value. This

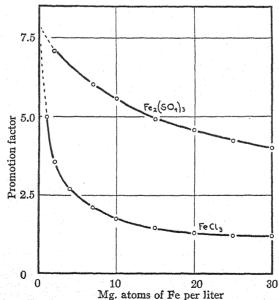

Fig. 5—Effect on the promotion factor of varying the concentration of primary catalyst is shown graphically in Fig. 5; it appears that the promotion factors for the two systems approach each other in magnitude as the concentration

of catalyst is decreased, thus indicating that in very dilute solutions of the catalyst the mechanism of promotion is independent of the nature of the anion.

It may be noted here that the promotion factor is the same when ferrous sulfate is the catalyst as when ferric sulfate is used, in dilute solution.

This fact is in accord with the initial 300 rapid oxidation of ferrous sulfate, discussed in the previous paper.

Effect of Concentration of Free Acid.—The effect of acid on the promoter action has already been partly shown in Curve II, Fig. 3, where it is seen that in the sulfate system the maximum effective concentration of copper is not changed by a decrease in the acid concentration: it can be shown that the promotion factor for $C_{\rm Fe} = 7.6$ is 5.8 whether the acid concentration is 0.038 N or 0.076 N. Similarly, for the chloride system, the promotion factor also remains unaltered when the concentration of free acid is changed from 0.076 N to 0.038 N. This is shown by the data of Tables VII and VIII, and in the curves of Fig. 6. The promotion factors obtained by interpolation from the latter are compared in Table VIII with those obtained from Fig. 1.

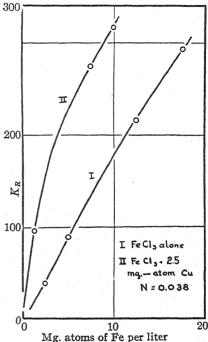

Fig. 6.—Promoter effect in the presence of decreased acid concentration

The fact that free acid has the same effect on the accelerated reaction that it has in the presence of iron salt alone, further confirms the hypothesis that the iron salt is the primary catalyst and the copper salt the promoter.

TABLE VII

EFFECT OF DECREASED ACID CONCENTRATION ON THE FERRIC CHLORIDE-COPPER CHLORIDE CATALYSIS

2	3.6	3.5	7	2.1	2.1
4	9.7	2.7	10	1 7	1.8

Effect of Temperature.—The effect of temperature on the extent of promotion is also negligible. It is shown in Table IX that the promotion factor in the chloride system remains constant, even though the reaction rate is greatly increased by raising the temperature. That the temperature coefficient is unchanged by the presence of copper is shown by Table X; this is again evidence for the hypothesis that the copper salt present activates the iron salt.

the catalysts, has been shown in a previous paper. The effect of such salts when copper is present as a promoter is shown in Fig. 7, the data being given in Table XI. A comparison of these results, plotted logarithmically,

with those presented in the previous paper shows that the rate due to molecular salt is accelerated, as well as the rate due to iron ions.

The Mechanism of Activation

It was shown in the previous paper² that the decomposition of hydrogen peroxide by iron salts 100 alone is due to the formation and subsequent reduction by hydrogen peroxide of an intermediate compound, probably H₂FeO₄. The rate of evolution of oxygen from a given concentration of hydrogen peroxide is proportional to the concentration of the intermediate compound, which is in turn dependent upon the concentration of iron salt and Fig. 7.—Effect of neutral salts on the promoof acid, and differs notably, de-

ter action

pending upon whether the chloride, sulfate or nitrate of iron is used. other words, the rate of reaction measured by the gasometric method can be no faster than the slower of the intermediate reactions, whether this be the formation of ferric acid, or its reduction by hydrogen peroxide, or some step in these processes. It is conceivable that the promoter, which is thus a secondary catalyst, might accelerate either one or both of the intermediate processes.

Two equal portions of a solution of barium ferrate in acetic acid were allowed to react with equal quantities of hydrogen peroxide. To one of the samples a very little copper acetate was added; measurements of the oxygen evolved showed that this one reacted much faster than the one to which no copper salt was added. This is an indication that the copper accelerates the reduction of the intermediate compound.

This experiment is not sufficient to explain the noticeable fact (compare Fig. 1 with Fig. 4) that although the rate for a given iron concentration is much lower when the sulfate is used, the maximum "promoted" rate is very close to that obtained when the chloride is used. If, however, we assume that the copper salt also accelerates the formation of the intermediate compound, the facts are more easily understood. It is probable, therefore, that the copper acts as a secondary catalyst, accelerating both the intermediate reactions. The exact mechanism of this secondary catalysis is not yet clear.

Summary

- 1. A small amount of copper salt greatly accelerates the decomposition of hydrogen peroxide by iron salts in acid solution. Other metallic salts do not appear to have this "promoter effect."
- 2. For a given concentration of iron salt, either sulfate or chloride, there is a maximum rate of reaction with about 1 millimole per liter of added copper salt. This maximum effective concentration of copper appears to be independent of the concentration of iron salt.
- 3. The extent of promotion (measured by the "promotion factor," which is the ratio of the maximum rate to the normal rate for the iron alone) is independent of the acid concentration and temperature.
- 4. The extent of promotion is much greater for ferric sulfate than for ferric chloride, although the maximum rate obtained in each case is the same. The promotion factors for the two systems approach each other as the concentration of iron approaches zero.
- 5. The facts are best explained by the following assumptions regarding the mechanism of promotion. (a) The iron salt is the primary catalyst, by virtue of its ability to form an intermediate compound. (b) The copper salt is a secondary catalyst, accelerating both the formation and subsequent decomposition of the intermediate product. The effect of the secondary catalyst is dependent upon its concentration only for very small quantities, a maximum effective concentration being noticeable. The mechanism of this secondary catalysis has not yet been completely explained.

FERRIC SALT AS THE "SOLUTION LINK" IN THE STABILITY
OF FERRIC OXIDE HYDROSOL¹

By Arthur W. Thomas and Alexander Frieden Received June 13, 1923

Ferric oxide hydrosol was first prepared by Arnold Maus.² It was regarded as a chemical compound³ until the introduction of the process of dialysis. Péan de St. Gilles⁴ and Thomas Graham⁵ looked upon it as

- ¹ This work was completed in February, 1922, and is adapted from the dissertation submitted by Alexander Frieden in partial fulfilment of the requirements for the degree of Doctor of Philosophy in the Faculty of Pure Science, Columbia University, 1922.

a soluble form of ferric hydroxide containing "impurities" but it soon became apparent⁶ that at least some of the impurities associated with this modification of hydrated ferric oxide were necessary for its stability in solution, as was found in the case of diverse colloidal dispersions, resulting in the evolution of the complex theory of colloids.⁷

Numerous attempts have been made to determine the relationship of the adsorbed electrolyte to the adsorbent, ferric oxide.⁸ Of these, the work of Linder and Picton,⁹ Malfitano,¹⁰ and Nicolardot¹¹ are important, though of little quantitative significance in the light of improved methods of investigation available at the present time. Interesting quantitative relationships have been obtained by Neidle,¹² by Pauli and Matula¹³ and, since the completion of this work, by Mathews and Browne,¹⁴ and by Browne,¹⁵

The object of this research was to obtain quantitative relationships between the substances that make up the colloidal particles and to determine the amount of electrolyte required to keep the particles dispersed.

Method

Preparation of the Hydrosols.—(1) About 14 M ammonium hydroxide solution was delivered drop by drop from a buret into a 3 M solution of ferric chloride, which was continually and vigorously agitated by a motor stirrer. The addition of ammonium hydroxide solution was continued until the resultant precipitate was peptized with great difficulty.

- (2) Ammonium hydroxide was added as above until a permanent precipitate was just formed; 0.33 *M* ferric chloride solution was then added, and the mixture stirred until the precipitate dispersed.
- (3) To a hydrosol prepared by Method 1 ferric chloride solution was added until the entire sol precipitated, and the resulting precipitate was dispersed in distilled water.
- (4) Fifty cc. of M hydrochloric acid was added to a freshly prepared and washed precipitate of ferric hydroxide prepared from 250 cc. of 3 M ferric chloride solution. The mixture was allowed to stand until the precipitate was peptized.

The hydrosols prepared by the first two methods were blood-red and perfectly clear to reflected and transmitted light. Those prepared by the third method were clear to transmitted, but slightly turbid to reflected light, while the sols prepared by the last method were decidedly turbid to reflected, although clear to transmitted light.

Dialysis.—Cups¹⁶ of very fine, unglazed porcelain were first tried as dialyzers. It was found, however, that these were permeable to ferric ions for only a short time. After a few days of dialysis, there was but a slight amount of ferric ion in the diffusate, though the hydrosol in the cup contained a large amount of ferric chloride. Evidently the membrane of ferric oxide formed within the walls of the cup is impermeable to ferric ion.

Unglazed porcelain cups could not, therefore, be used at this stage of dialysis. In subsequent dialysis experiments, in which all of the unadsorbed ferric chloride had left the solution and further dialysis was merely a slow hydrolysis, porcelain cups of smaller size and thinner wall were employed. These were permeable to chloride and hydrogen ions.

For the preliminary dialysis, collodion bags were employed. These bags were prepared in a 2-liter Florence flask and were changed as soon as a coating of ferric oxide had been formed on the walls of the membrane, in order to speed up the process of dialysis. Some of these sols were dialyzed at room temperature and others at 60°. The diffusate was changed every 24 hours, distilled water being used throughout. The preliminary dialysis was considered complete when the diffusate of 24 hours, usually 1 liter in volume, acidified and evaporated to 10 cc., showed no color upon addition of 5 cc. of M ammonium thiocyanate solution. In view of the high delicacy of this test for the ferric ion, its concentration in the hydrosol is negligible at this point. (The ratio 17 of the concentration in moles of ferric oxide to that of ferric chloride, Fe₂O₃/FeCl₃, was about ten at this point.) The test for the ferric ion as given by ammonium thiocyanate applied to the sol directly was negative long before this ratio was reached. The ammonium chloride formed in the preparation of the sol disappeared within a comparatively short time.

The length of time required for the completion of dialysis varied from 2 to 5 months, depending upon the concentration of the sol and the temperature at which the dialysis was performed. Excessive dilution of the dialyzing hydrosol was avoided by having the level of the water in the outer vessel much lower than that of the hydrosol inside.

¹⁶ Obtained from Coors Porcelain Company, Golden, Colorado.

¹⁷ The values given throughout this paper were obtained as follows. The chlorine found by analysis was calculated to ferric chloride; the ferric chloride computed to ferric oxide which was subtracted from the total ferric oxide (from total iron found by analysis), giving the values of ferric oxide cited.

Analyses

Iron.—The solution was evaporated with sulfuric acid until fumes of sulfur trioxide formed and was then reduced in a Jones reductor and was determined by titration with potassium permanganate.

Chlorine.—To a definite volume of the hydrosol, nitric acid was added to make the final concentration about 3 M. The covered beaker was allowed to stand in the dark until all of the ferric oxide had dissolved, which usually required a week or 10 days. Approximately 0.1 M silver nitrate was then added in excess of the amount necessary to precipitate all the chloride. A slight variation in the procedure was to add the silver nitrate before the addition of nitric acid. Separate experiments on pure potassium chloride showed that the procedures could be used interchangeably, and that there was no danger of loss of chloride by oxidation. The chloride concentration was determined either gravimetrically or by the method of Volhard.

Experimental Part

At the beginning of this investigation, measurements of the conductivity of ferric oxide hydrosol during dialysis were made in the hope of getting quantitative indication of an end-point in the purification. The measurements showed, as anticipated, that the conductivity gradually decreases as dialysis proceeds, but after a certain time the hydrosol showed a conductivity lower than that of the distilled water against which it was being dialyzed. The conductivity of ferric oxide hydrosol has been reported by several investigators, 10,13,18 but the results differ widely because of the variable quantities of peptizing electrolyte present and are obviously of no value.

Due to the failure of the conductivity method, the measurement of the depression of the freezing point was tried, and since this also failed to serve our purpose (see later), the observation of beginning of precipitation was adopted as end-point in dialysis. The incipience of precipitation does not mean the coagulation of the hydrosol, since thereafter precipitation proceeds gradually, the system assuming a turbid appearance which increases with continued dialysis until finally the entire sol becomes a gel.

Two and one-half liters of a sol (Fe₂O₃, 9.3105; FeCl₃ 0.7143 g./liter; ratio, 13) was dialyzed for 4 weeks at room temperature against a volume of 1 liter of distilled water, the outside water being changed several times each day for the first week and once a day thereafter. Samples were withdrawn for analysis at frequent intervals until precipitation began. At this point the hydrosol contained 3.2653 g./liter of ferric oxide and 0.1539 g./liter of ferric chloride, that is, a molar ratio, Fe₂O₃/FeCl₃, of

¹⁸ Duclaux, Compt. rend., 140, 1468 (1905); Kolloid Z., 3, 126 (1908). Goodwin and Graver, Phys. Rev., 9, 251 (1896); 11, 193 (1900). Dumanski, Z. physik. Chem., 60, 553 (1907).

21.5. The dialysis was continued for 10 weeks, until all of the sol was converted to a gel in which the molar ratio of ferric oxide to ferric chloride was 48.

A sol was dialyzed at 60° for 10 weeks. At the end of this time, the 24-hour diffusate when evaporated to 10 cc. gave no test for ferric ion. The sol then contained 8.1017 g./liter of ferric oxide and 0.8397 g./liter of ferric chloride. When precipitation began (after 18 days) the hydrosol contained 1.1961 g./liter of oxide and 0.0593 g./liter of chloride thus showing a molar ratio of 20.5.

This would seem to indicate that dilution has no marked effect on the point at which precipitation begins.¹⁹ To verify this, two sols of molar ratios 11.7 and 12.9 were made up to various dilutions and dialyzed in collodion bags to the first appearance of a precipitate. The two series showed identical results, the first of which is described in Table I.

TABLE I

EFFECT OF DILUTION ON END-FORT								
Dilution	none	1.87	3.04	7.75	13.80

Ratio of Fe ₂ O ₃ to FeCl ₃	12^{a}	21	22	21	21			

^a Original sol. not dialyzed to incipience of precipitation.

It was deemed probable that the gradual precipitation, which sets in after the initial appearance of precipitate, might be due to excessive hydrolysis and dialysis near the walls of the collodion bags. If so, this would affect the limiting ratio. To test this probability, a series of sols was dialyzed in small, unglazed porcelain cups. The solutions were stirred throughout the entire period by a current of nitrogen, kept at a temperature of 50–60°, and analyzed when a turbidity became perceptible.

The data in Table II are taken from one of two series of different sols which gave identical results. The sol used in Table II contained 5.867 g./liter, of ferric oxide and 0.3743 g./liter, of ferric chloride; ratio = 16.

TABLE II
EFFECT OF DILLITION ON END-POINT

Dilution	none	1.33	2.00	2.66	4.00

Ratio of Fe ₂ O ₃ to FeCl ₃	20	20	21	20	22		

Following the incipience of precipitation, gradual flocculation was observed in all cases. Analyses of samples of such sols showed that their molar ratios of ferric oxide to ferric chloride gradually increased as dialysis

¹⁹ The value at which incipience of precipitation is found and the fact that dilution of the sol does not affect it are not in agreement with the experience of Neidle, Ref. 12.

continued to final complete precipitation. These analyses were not very accurate because it was impossible to free the hydrosol entirely from precipitated particles that were held in suspension. Centrifuging at about 1000 "times gravity" for the purpose of removing these suspended particles frequently resulted in the breaking out of the entire dispersed phase from dispersion in the form of a fairly continuous jelly phase. This is rather significant in that it suggests a jelly-like structure of this hydrosol. Due to the inaccuracies of the analyses the results are not reported, but it is of interest to recall that Duclaux²⁰ claimed that ferric oxide hydrosol could be dialyzed to a limiting value of 170 Fe₂O₃. 1FeCl₃.

Since the dispersed phases of hydrosols, prepared as just described, migrate to the cathode when subjected to the action of an electrical current, the particles are said to be positively charged due to the ferric chloride of the complex, the ferric ions thereof remaining in contact with the ferric oxide while the chloride ions are located in the water phase directly bathing the particles. Since like charged bodies repel one another, the electrical charges of the particles are supposed to overcome the mutual attractive forces of the particles, a rather commonly accepted explanation for the stability of inorganic colloidal particles.

According to this explanation, the limiting ratio of ferric chloride to ferric oxide should increase with increased concentration of the particles, since the mutual attractive force varies inversely as some power of the distance between the particles. The more closely the particles are packed, the greater should be the charge required to keep them repelling one another.

Examination of the data reveals no such tendency. Apparently the electrical charge is not the predominating factor for the stability.²¹ The

In his famous paper on the "Mathematical Theory of the Kinetics of the Coagulation of Colloidal Solutions," M. v. Smoluchowski [Z. physik. Chem., 92, 129 (1917)] arrives at conclusions identical with the statements of Professor Porter quoted above.

²⁰ Duclaux, Compt. rend., 143, 296 (1906).

²¹ In connection with this statement it is timely to quote the criticism of the electrical charge theory of stability recently made by Porter and Hedges [Phil. Mag., 44, 641 (1922)]: "If the particles really contained charges all of one sign only they would tend to move toward the boundary. This is the equivalent of the fundamental electrical fact that statical charges reside close to the surface of conductors. When we are dealing with large particles instead of electrons, there is no doubt that they would occupy a larger region, instead of a thin superficial area, but still there would be an accumulation at the boundary. This is the opposite to what is observed." "But the charges in the solution are not only of one sign. The solution, as a whole, is uncharged; consequently an equal opposite charge is to be looked for. This opposite charge is the second member of the double layer close to the surface of each particle. When the existence of this double layer is recognized, the electric forces between the particles become zero, except insofar as relative displacement takes place by induction between two members of a layer so as to give it an electrical movement. In this case the force between two such doublets in the equilibrium state will, on the average, be an attraction and not a repulsion."

fact that the limiting ratio, that is, the point corresponding to incipience of precipitation, is always nearly the same²² indicates that regardless of the concentration of the sol, 1 mole of ferric chloride is required to keep about 21 moles of ferric oxide dispersed in the colloidal condition.²³ Any amount of ferric chloride in excess of this ratio might be regarded as impurity. The stability of the ferric oxide hydrosol must then be due not to the electrical charge of the particles but to the solution forces (solubility) of the adsorbed ferric chloride. The high solution forces of the ferric chloride molecules pull the ferric oxide particles with which they are combined by secondary valence or "adsorption forces" into semisolution. Upon removal of the ferric chloride by hydrolysis the insoluble particles of ferric oxide, having lost their "solution-link," precipitate.

According to the "solution-link" hypothesis this hydrosol should be soluble in any liquid in which ferric chloride dissolves. It was found that dilution of the hydrosol with an unlimited amount of alcohol had no effect upon its appearance, nor did the addition of ether to this alcosol precipitate it, provided a large excess was not added.

An iron oxide hydrosol stabilized by ferric sulfate should be precipitated by alcohol according to the hypothesis. Such a sol was prepared resembling the Péan de St. Gilles sol in appearance. Addition of alcohol precipitated it instantly.

Hydrogen-Ion Concentration.—Pauli and Matula¹³ attempted to measure the hydrogen-ion concentration of ferric oxide hydrosols. Good results were obtained by them when using sols which had "aged" for 6 months or which were heated for a few hours at 80°, this being equivalent to aging, that is, hydrolyzing excess ferric chloride. Their measurements had to be made quickly and their platinum electrodes were saturated with hydrogen before coming in contact with the hydrosol to be measured. The results indicated that the hydrosols were neutral,²⁴ that is, had a hydrogen-ion concentration of the order of 10⁻⁷.

Measurements of hydrogen-ion concentration would be impossible in the presence of ferric ion for obvious reasons. Using well dialyzed sols in which the concentration of ferric ions was supposedly nil, we found no evidence of a reducing potential but could not get what is considered to be an absolutely satisfactory equilibrium reading due to the deposition of ferric oxide gel upon the platinized electrode. However, taking the mean of a series of readings which were not widely divergent, a hydrogen-

 $^{^{22}}$ The slight deviations from the value of 21 may be ascribed as due to errors in the determination of the end-point of dialysis by means of the observation of the beginning of precipitation.

²³ This is the "purity" at which Browne (Ref. 15) found the heat of coagulation of ferric oxide hydrosol to be practically zero.

²⁴ Very recently, Browne (Ref. 15) using a similar method also reports that ferric oxide hydrosols are neutral.

ion concentration of $10^{-4.9}$ was indicated. This was the same for a series of our "pure" hydrosols of various concentrations and consequently the hydrogen-ion concentration does not appear to depend upon the concentration of the dispersed phase, at least over the range which we studied. We should say that our "pure" ferric oxide hydrosols showed a hydrogenion concentration of 10^{-5} .

An acid reaction is to be expected, since upon dialysis of sols from which the free ferric chloride has been removed only hydrogen and chloride ions are found in the diffusate across the collodion membrane. Consequently, the ferric chloride of the dispersed phase is in equilibrium with the ions of hydrochloric acid in the dispersion medium, which in the case of our "pure" sols is of the order of $0.00001\ M_{\odot}$.

Behavior upon Freezing.—As previously mentioned, freezing-point depression was tried as a quantitative method for following purification, but it was found that a well dialyzed sol gives a depression of the freezing point within the range of experimental error of measurement with the Beckmann thermometer.

Péan de St. Gilles was inclined to regard his hydrosols as true solutions because they froze in a "normal" manner. In 1889, Ljubawin²⁶ froze, among other colloidal substances, ferric oxide hydrosol and found that as the liquid cooled, particles of ferric oxide concentrated in the center while the periferous layers of the ice became colorless. When the mass was melted again, all of the iron oxide particles redispersed. Lottermoser²⁶ found that only those sols which are deficient in electrolyte were precipitated on freezing. Sols rich in electrolyte were not affected even upon continued freezing.

Our experiments showed that when a pure ferric oxide hydrosol is only partially frozen, ice crystals are formed which upon melting leave the sol as homogeneous in appearance as it was before the operation. But when cooling is continued until freezing is complete, some precipitation is noted when the mass melts. The longer the sol has been cooled, the greater will be the amount of gel formed. The precipitate is in the form of short, amorphous, shiny, needle-like particles. When the sol is allowed to remain in contact with the ice-salt mixture for some length of time, the entire solution turns to a dark red, solid mass. When cooling is continued separation of the water begins as a layer of colorless ice near the walls of the test-tube, and such layers continue inward until, in the center, there are deposited the red brown particles above described. These particles are arranged in a string-like formation throughout the height of the tube. When the ice is melted they do not redisperse. The water obtained by melting the ice shows a barely perceptible test for chloride ion and none

²⁵ Ljubawin, Z. physik. Chem., 4, 486 (1889).

²⁸ Lottermoser, Ber., 41, 3976 (1908).

for ferric ion. The gel particles are practically insoluble in dil. nitric acid, but readily soluble in concentrated acid. Analysis showed that about 80% of the ferric chloride of the original hydrosol particles was retained in this gel. This behavior is quite different from that of Bredig gold hydrosols upon freezing, since Beans and Beaver²⁷ find that all of the stabilizing electrolyte is removed from the gold particles through the congelation.

These observations support the conclusion that the stability of these hydrosols is due to the solution forces of the adsorbed ferric chloride rather than to the electrical charge of the particles.

The ferric chloride in the congelation gel from the pure sols must be dispersed throughout the compact solid mass, for although there is sufficient ferric chloride present to redisperse the particles, at least partially, such redispersion does not take place; but when an impure sol is frozen, that is, one to which some ferric chloride has been added, the gel particles redisperse upon melting; this is like the experience of Gutbier and Flury²⁸ with selenium oxide sols.

Relationship Between Graham's Hydrosol and the So-Called "Meta-iron" Hydrosol of Péan de St. Gilles. Water of Hydration.—The hydrosol that Péan de St. Gilles prepared by heating and boiling solutions of the acetate differed slightly in properties from Graham's in that it was not so clear and that a precipitate formed on continued heating which was insoluble in concd. acids but soluble in dil. acids and water. Graham, in analogy to the two modifications of tin oxide sol, called it the "meta-iron" oxide hydrosol, an appellation that is still used.

In the course of this investigation, it was found that this conception of two modifications of ferric oxide hydrosol is not justifiable, the main difference between the two being water of hydration of the particles, as suggested by others.^{29,30}

This was demonstrated as follows. A hydrosol prepared by Method 3 was dialyzed at room temperature until it showed the molar ratio, Fe₂O₃/-FeCl₃ = 18. A portion of this sol was then dialyzed in a porcelain cup at about 60° while it was continuously stirred with nitrogen and was analyzed (a), after 5 days of dialysis, and then again (b) after 9 days. In (a) incipience of precipitation was not evident while in (b) a decided precipitation had started. The ratios of Fe₂O₃/FeCl₃ were (a) 20 and (b) 26. Another hydrosol prepared by peptizing ferric hydroxide gel with a small amount of hydrochloric acid was dialyzed as described above. This initially turbid sol increased in turbidity as dialysis was continued so that

³⁰ Bancroft, J. Phys. Chem., 19, 232 (1915).

the beginning of precipitation could not be determined accurately. When the end-point was presumed to have been reached, it showed upon analysis a ratio, $Fe_2O_3/FeCl_3 = 23$.

It is thus seen that the limiting value for these "meta-iron oxide," or Péan de St. Gilles' sols is of the same magnitude as that of the Graham sol. This would indicate that the turbidity of this sol is due to dehydration rather than to the presence of larger ferric oxide aggregates.

Since, according to Einstein,³¹ the viscosity of a colloidal dispersion is expressed by the formula $\eta' = \eta(1+kf)$, where η' is the viscosity of the system, η the viscosity of the dispersion medium, and f the ratio of the total volume of the dispersed phase over the total volume of the system, which means as Wo. Ostwald³² and others have shown that the viscosity of a colloidal solution increases with the amount of the dispersion medium taken up by the dispersed phase, the Péan de St. Gilles sol should have a lower viscosity than the Graham sol of the same concentration if our supposition is correct.

To determine whether this is the case, 10cc portions of a Graham hydrosol were treated with various amounts of 2N ferric chloride solution until the turbidity which first appeared gradually changed to a coarse bright yellow dispersion³³ and the viscosities were measured.

The measurements were made by means of an Ostwald viscometer, in a constant temperature bath at $25 \pm 0.01^{\circ}$. Table III shows the results. The figures signify the time in seconds for outflow.

Table III Viscosity of Graham Hydrosol, No. 15

FeCl ₃ Expt.	added Cc.	Time. Sec.	Comparative data	Time Sec.
2	0.1	73	Pure hydrosol (Expt. 1)	81
3	0.2	73	Distilled water	71
4	0.3	74	10 cc. dist. water + 2 cc. of 2 N FeCl ₃	-80
5	0.5	75	10 cc. dist. water + 10 cc. of 2 N FeCl ₃	137
6	1.0	78		
7	2.0	99		

No. 1 was perfectly clear; Nos. 2, 3, 4 and 5 were clear to transmitted, but turbid to reflected light. They resembled the Péan de St. Gilles sol in all respects. The turbidity gradually increased with increasing amounts of ferric chloride. No. 6 was decidedly brown while No. 7 was yellow. After three hours, the viscosities were again measured and found to be unchanged.

From these results it is seen that the addition of ferric chloride first decreases the viscosity and then increases it. The decrease in viscosity

³² Wo. Ostwald, Trans. Faraday Soc., 9, 34 (1913).

³³ A sol so treated is identical in appearance with the "meta-iron oxide" modification.

indicates a diminution in size of the particles which could only have been caused by a loss of water of hydration by the dispersed phase. The increase in viscosity observed upon the addition of larger amounts of ferric chloride is due to the coalescence of the particles preliminary to precipitation.

As to the mechanism of the dehydration of the sol by ferric chloride, we can only venture to say that it is possibly due to the high hydration of the electrolyte added, thus causing a partial dehydration of the dispersed Fe₂O₃–FeCl₃–H₂O phase, or in view of the fact that this sol migrates in an electrical field showing that the adsorbed and peptizing electrolyte is ionized, even though the degree be extremely small, then the Donnan effect of the added ferric chloride would result in a decrease in swelling (hydration) of the dispersed phase as in the case of the addition of hydrochloric acid or a neutral salt to gelatin jelly swollen in a solution of hydrochloric acid. Both suggested mechanisms may operate at the same time.

Summary

Evidence is submitted which indicates that the stability of ferric oxide sol, stabilized by ferric chloride, is due to the solubility (or solution forces) of the adsorbed ferric chloride in the dispersion medium, rather than to the mutual repulsive forces of the particles presumed to reside in their electrical charges of like sign. The so-called "meta-iron" sol of Péan de St. Gilles is one in which the particles of the dispersed phase are less hydrated than in the Graham ferric oxide hydrosol.

THE MECHANISM OF THE MUTUAL PRECIPITATION OF CERTAIN HYDROSOLS¹

By Arthur W. Thomas and Lucille Johnson Received June 13, 1923

The literature² concerning the mutual precipitation of hydrosols treats this phenomenon as an electrical one by which the positively charged particles of one hydrosol neutralize the negatively charged particles of the

other, but the recent discovery by Freundlich and Nathansohn³ showing that arsenious sulfide hydrosol and sulfur (Odén) hydrosol precipitate each other, although both are "negatively charged," is not amenable to explanation by this hypothesis. A satisfactory chemical explanation is available, however.

A short paper by Lottermoser⁴ in 1910 suggested a chemical mechanism for mutual precipitation of colloids which was based upon a few experiments with silver iodide hydrosol peptized by silver nitrate (or by silver ion) and silver iodide sol peptized by potassium iodide (or the iodide ion). He found sharpest and most complete mutual precipitation in those mixtures where the amounts of peptizing silver nitrate and potassium iodide were in, or very near, chemical equivalence.

In the belief that mutual precipitations of colloids are chemical phenomena this investigation was undertaken. A series of "positively charged" ferric oxide hydrosols was treated with a number of "negatively charged" silicic oxide hydrosols and the precipitation quantitatively studied from the contents of peptizing electrolyte. The reaction between ferric oxide sols and arsenious sulfide sols was followed qualitatively.

Preparation and Analysis of Ferric Oxide Sols

Preparation.—Ferric oxide sols were prepared by adding $2\,M$ ammonium hydroxide very slowly, by dropping from a buret, to $2\,M$ ferric chloride solution which was vigorously stirred until the precipitated ferric hydroxide ceased to peptize or "dissolve" easily. The sols, which were very dark in color, were dialyzed in collodion bags against distilled water until the desired degree of "purity" was reached.

Analysis.—Iron. Three cc. of concd. sulfuric acid was added to 25 cc. of sol and the solution evaporated to dryness on a hot-plate. This was to insure removal of chlorine. The dried residue was dissolved in 150 cc. of water, 10 cc. of 18 M sulfuric acid added, the solution passed through a Jones reductor and titrated with standard potassium permanganate. Correction was made for the reducing of a blank of sulfuric acid.

Chlorine by Volhard's Method.—Ten cc. of nitric acid prepared by diluting concd. acid (d., 1.42), from which all oxides had been removed, with an equal volume of water, was added to 50 cc. of the sol and the mixture allowed to stand in a dark, cool place until the solution was clear. An excess of standard 0.1 M silver nitrate solution was added, the silver chloride filtered off and the excess titrated with 0.1 M potassium thiocyanate solution using the iron as indicator.

TABLE I

The amount of iron as iron chloride was calculated from the chlorine and this subtracted from the total iron gave the iron from which ferric oxide was calculated.

Silicic Acid Sols

Preparation.—Silicic acid sols were prepared by dissolving water glass (d., 1.4) in 10 times its weight of water and partially neutralizing to various degrees with hydrochloric acid. The sodium chloride formed was not removed because (1) the freshly prepared sols diffused quite readily through unglazed porcelain dialyzers and through ordinary collodion sacks; these sols after standing showed aggregation of particles (became opalescent) and then would not diffuse through the septa mentioned; but removal of sodium chloride by dialysis would also remove sodium hydroxide formed by hydrolysis of sodium silicate, which was not desired; (2) the presence of the sodium chloride did not complicate the results, as shown later.

Analysis.—Silicic Acid. To a portion of the sol was added several cubic centimeters of $12\ M$ hydrochloric acid and the mixture was evaporated to dryness. The residue was twice wet with hydrochloric acid and evaporated to dryness, after which it was washed free from chlorides and weighed as silicon dioxide.

Sodium Silicate.—A portion of the sol was diluted with four or five times its volume of water, making a total volume of 100 or 200 cc., depending on the concentration of the sol. Ten cc. of a concd. solution of sodium chloride was added to replace sodium hydroxide which might be held in the dispersed phase, and the solution titrated with $0.1\,M$ hydrochloric acid, using phenolphthalein as indicator. After neutrality was apparently reached the solution became pink upon standing, and a few drops of acid were necessary to discharge the color. To avoid errors due to this, a check was run by adding an excess of acid and titrating with sodium hydroxide; the results checked within 2%, which is well within the error of the subsequent determinations of precipitation ratios.

Sodium Chloride.—The sodium chloride was calculated from the amount of hydrochloric acid added to the water glass to form the silicic acid sol.

As no definite formula can be given for the sodium silicate, the concentrations are expressed in terms of silicon dioxide for silicic acid and sodium hydroxide for the stabilizing sodium silicate.

TABLE II
COMPOSITION OF SILICIC ACID SOLS
In moles per liter

No.	1	2	3	4	5
SiO ₂	0.221	0.208	0.305	0.437	0.186
NaOH	0.0327	0.0356	0.0294	0.135	0.0115
SiO ₂ : NaOH	6.7/1	5.8/1	10.4/1	3.5/1	1.6/1
NaCl	0.091	0.081	0.142	0.111	0.093

Procedure

Various amounts of one sol were run from a buret into hard glass, bacteriological tubes of uniform diameter and clearness and about 20 cc. in volume. Equal volumes of the other sol were run from a pipet or buret into the tube as quickly and as quietly as possible to avoid mixing. The tubes were inverted two or three times with as little agitation as possible, to insure complete mixing of the sols. This was sufficient if the tubes were not more than $^3/_4$ full and were revolved as they were inverted. The point of maximum precipitation could be clearly seen by successive stages; first, the greatest cloudiness in the series, followed by the first separation of par-

ticles, and usually the first sediment. The last was frequently over a wider range than the first two stages as the precipitating zone widened rapidly. All observations were made immediately after mixing by holding the series of tubes against a clean or open window. Artificial light was found to be quite unsatisfactory, as was the light late in the afternoon or on a dark day.

Some series precipitated more easily than others, probably because of greater agitation. Vigorous shaking usually precipitated the whole series immediately. A tube of greater diameter than the others or of cloudy or marked glass appeared more cloudy and consequently was misleading. A few series were centrifuged, but the time required in placing them in the centrifuge and the force to throw out the fine particles resulted in complete precipitation over a wide range.

To avoid errors due to an unclean tube or some other factor, three or four determinations were made in each instance.

The effect of dilution of the sols is given in Table III.

Table III

Effect of Dilution upon Mutual Precipitation
Cc. Precipitation Millimole

Ŧ	Cc. e ₂ O ₂ sol No. 6	Ce, SiO ₂ No. 1	Precipitation results	HCl Millir	noles NaOH
	(Dilution 1:				1,0024
	5.3	1 to 10	All coagulated to solid		
2.	(Dilution 1:	10 1:50)			
	5.3	3.0	Partial)		
	5.3	3.5	Almost complete (0.00004	a angen
	5.3	4.1	Complete	0.00284	0.00268
	5.3	4.5	Almost complete		
3.	(Dilution 1:	50 1:250)	,		
	5.3	4.5	Partial		
	5.3	4.8	Complete	0.00057	0.00004
	5.3	$5.1 \stackrel{?}{)} 4.9$	Complete	0.00007	0.00064
	5.3	5.4	Partial		
4.	(Dilution 1:	100 1:250)			
	10	4.7	Much slower		
	10	5.0	First to ppt.	o occar	0.00050
	10	5.3	Much slower	0.00065	0.00053
	10	5.6	Much slower		

This table shows that the dilution of mutually precipitating sols narrows and sharpens the zone of maximum precipitation, and that the variation in ratio between the sols varies no more than in successive experiments with the same dilution. If carried beyond certain dilutions coagulation is almost imperceptible or is so slow that it is very difficult to determine. The dilutions used for the work were the greatest giving sharp precipitations. Very unstable sols show considerably different ratios with dilution. This will be discussed later.

To avoid possible differences due to order of mixing, the order was always reversed at least once.

Table IV gives the data found in determining the points of maximum precipitation in cases typical of 37 experiments made, and Table V shows results obtained with one silica sol and several ferric oxide sols, which are typical of two other similar series.

TABLE IVA

MUTUAL PRECIPITATION OF SILICIC ACID HYDROSOL NO. 1 WITH FERRIC OXIDE HYDROSOL NO. 20

Dilutions: Fe_2O_3 sol = 1:25 SiO₂ sol = 1:200 5.3 cc. of ferric oxide sol added to silicic acid sol

First test		Second test		
Cc. SiO ₂ soI	Results	Ce. SiO ₂ sol	Results	
4:0	Partial precipitation	4.5	Partial later precipitation	
5.0	First and heaviest precipitate	5.0	The 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	
6.0	Partial precipitation	5.5∫	First to precipitate	
7.0	Only slightly cloudy	6.0	Partial later precipitation	

It was evident that 5.2 cc. of silicic acid sol with 5.3 cc. of ferric oxide sol gives the maximum precipitation.

TABLE IVB

Silicic acid sol added to 5.3 cc. of ferric oxide

Cc. SiO ₂ sol	Results	Cc. SiO2 sol	Results
4.8	Fourth to precipitate	5.4	Second to precipitate
5.0	Second to precipitate	5.6	Third to precipitate
5.2	First to precipitate		

Maximum precipitation is obtained with 5.2 cc. of silicic acid sol and 5.3 cc. of ferric oxide sol.

TABLE V

THE RATIO AT MAXIMUM PRECIPITATION OF SILICIC ACID SOL NO. 1 TO DIFFERENT FERRIC OXIDE SOLS

			aprette Carryay	POSTANI

6	1:100	10.0	.00054	.00065	5.0	1:250
15	1:50	5.3	.00165	.00155	9.5	1:200
17	1:50	5.3	.00085	.00085	5.2	1:200
20	1:25	5.3	.00085	.00085	5.2	1:200
21	1:25	5.3	.00147	.00164	10.0	1:200
23	1:25	5.3	.00151	.00155	9.5	1:200

Silicic acid sol No. 4 was precipitated at different dilutions against ferric oxide sols Nos. 4, 6 and 20. No clear zones could be determined, but in every case the milli-equivalents of sodium exceeded the milli-equivalents of chloride.

The precipitating volumes checked within 10% in all cases except that of the very impure silicic acid sol No. 4.

To test the effect of the sodium chloride present upon the point of maximum precipitation 0.03 g. of sodium chloride (an amount equal to 60% of the amount of sodium chloride already present in the sol), was added to silicic acid sol No. 2 (diluted 1: 200), and the sol precipitated with several ferric oxide sols.

The results showed that the sodium chloride is without influence on the mutual precipitation of silicic acid sols and ferric oxide sols, and consequently no error was introduced by its presence in the silicic acid sols used.

TABLE VI

THE RATIO OF FERRIC CHLORIDE EXPRESSED IN EQUIVALENTS OF HYDROCHLORIC ACID
TO SODIUM SILICATE

Expressed in equivalents of sodium hydroxide in the thirty-seven precipitations of ferric oxide sol and silicic acid cited in the foregoing tables. The values are milli-equivalents of sodium hydroxide per 0.001 milli-equivalents of hydrochloric acid.

The soland since acid creed in the following teaches. The values are infine-equivalents of sodium hydroxide per 0.001 milli-equivalents of hydrochloric acid.

The sols are arranged in the order of their purity, the ratio of sodium silicate in terms of sodium hydroxide to silicon dioxide decreasing from left to right, and the ratio of ferric chloride to ferric oxide decreasing from top to bottom

Table VI shows that over a wide range of ratios between peptizing agent and dispersed phases of sols, there is a constant ratio between the peptizing agents of mutually precipitating sols and a greatly varying ratio between the dispersed phases. This leads to the conclusion that the precipitation is due to removal of the peptizing agents by a chemical action between them. As no definite formula can be given for the silicates it is impossible to express the reaction between sodium silicate and ferric chloride in an equation. However, the peptizing ferric chloride and sodium silicate can be given in terms of their hydrolysis products which are in equilibrium with the dispersed phase complexes, and consequently in the mutual precipitation of ferric oxide and silicic acid sols the reaction may be expressed as $HCl + NaOH \longrightarrow NaCl + H_2O$.

Another indication of such a reaction is given by the difference of hydrogen-ion concentration in the supernatant liquid of precipitation of varying degrees. Various amounts of silicic acid sol No. 3 (diluted 1:25) were added to 25 cc. of ferric oxide sol No. 4 (diluted 1:10), the precipitates allowed to settle and the hydrogen-ion concentrations of the supernatant liquids determined with the results given in Table VII. The ferric oxide sol showed a Sörensen value (Ph) of 5 while the silicic oxide sol was slightly alkaline to phenolphthalein.

Table VII
Change in Hydrogen-ion Concentration with Varying Precipitation of Ferric
Oxide and Silicic Acid Sols

Silicic acid Cc.	l sol Remark		Tegative log on concentration	1
10	Very slig	ht pptn.	5.6	
	Excess of	f Fe ₂ O ₃ sol		
16	Maximu	m pptn.	6.8	
18	2nd of se	ries to ppt.	7.8	
20	Slow potn. Ex	cess of SiO ₂ sol	>8.3 (Alkalia	ne to phenolphthalein)

Thus it is evident that maximum precipitation occurs at neutrality as the chemical equivalence of peptizing electrolyte demands and that the acidity increases with excess ferric oxide sol, and the alkalinity increases with an excess of silicic acid sol.

The ferric oxide sols, excluding Nos. 1, 2 and 3 (which contain the greatest amount of the peptizing agent in proportion to the dispersed phase), give a 1:1 ratio with silicic acid sols Nos. 1 and 2. With silicic acid sol No. 3, the same ferric oxide sols give a constant ratio with the ferric chloride of the same ferric oxide sols. As the sol becomes purer in respect to peptizing agent, it becomes more unstable and the precipitating ratios become more inconstant. This agrees with the general experience with "pure" ferric oxide sols. It is known that when a certain degree of "purity" is passed in a sol, the sol precipitates. The sol containing only a little more than the necessary minimum of peptizing agent is in a metastable condition, and the least disturbance will precipitate it. This may easily account for the ready precipitation of the pure ferric oxide sols.

The effect of diluting unstable sols in mutual precipitation is shown in Table VIII.

TABLE VIII

Precipitation of Ferric Oxide Sol No. 17 with Silicic Acid Sol No. 5 of Various Dilutions

Fe ₂ O ₃ sol, 1:50 M	illi-equivalen	ts of HCl, 0.00160	
SiO ₂ sol	1:50	1:100	1:200
NaOH, milli-eq	0.00057	0.00069	0.00080
NaOH eq. of HCl eq. %	35	. 43	50

Thus it is seen that the reaction between very "pure" sols tends to approach chemical equivalence upon dilution, which is to be expected since

the individual particles becoming widely separated upon dilution have less chance of aggregating and thus settling out. In the mean time there is more chance for a complete reaction between the peptizing agents.

Both ferric oxide and silicic acid sols show erratic results in precipitation, if they contain large amounts of peptizing agent. This is undoubtedly due to the fact that some of the unaffected peptizing agent is adsorbed in the coagulum and carried down with it.

Investigation of the Mutual Precipitation of Ferric Oxide and Arsenic Trisulfide Sols

The ferric oxide sols used in this work were the same as those used with silicic acid sols and the method of procedure was the same.

Arsenic Trisulfide Sols

Preparation.—Hydrogen sulfide was passed into a warm solution of arsenic trioxide prepared by dissolving from 5 to 10 g. of finely powdered resublimed arsenic trioxide in a liter of boiling water that had been boiled first to remove dissolved oxygen.

Analysis.—Attempts were made to drive over the excess hydrogen sulfide and thus determine it directly, but in every instance there was decomposition of the arsenic trisulfide. For example, 100 cc. of sol containing only 1 cc. of phosphoric acid (d., 1.7) was completely dissolved by 15 minutes' boiling. This was surprising in view of the generally accepted ideas of the stability of arsenic trisulfide, and may be due to its fine subdivision in the sol. At no time was there precipitation during the heating, unless electrolytes had been added to the point of precipitation.

Ward⁵ states that at temperatures below 35°, the adsorbed hydrogen sulfide can be evolved from arsenic sulfide without decomposition of the latter, but several attempts to remove only the hydrogen sulfide by passing carbon dioxide gas through the pure sol, or through the sol previously precipitated by neutral salts, resulted in appreciable decomposition and this technique was thereby proved valueless.

Freshly prepared sols were analyzed for total arsenic and sulfur. From the arsenic percentage, the amount of trisulfide present was calculated and the sulfur found in excess of that to give this amount was calculated as hydrogen sulfide of peptization. But the amount was so small that a very small error in the determination of either the arsenic or sulfur renders the results useless; thus, in one case an error of 0.1% in analysis made an error of 100% in the calculation of hydrogen sulfide of peptization.

Since a quantitative study of this mutual reaction is precluded, at least a qualitative test is justifiable. If in the mutual precipitation of ferric oxide sol and arsenious sulfide sol a chemical reaction takes place between the ferric chloride and hydrogen sulfide of peptization, one of the following reactions may take place: (1) $H_2S + 2FeCl_3 \longrightarrow 2FeCl_2 + S + 2HCl$; (2) $3H_2S + 2FeCl_3 \longrightarrow 2FeS + S + 4HCl$.

In most precipitations there is no evidence of the latter reaction, as the precipitate is yellow. When, however, the sol contains a great amount of hydrogen sulfide, a blackening develops which can be explained by the formation of ferrous sulfide.

⁵ Ward, Am. Chemist, 4, 10 (1873).

To test the supposition that the mutual precipitation between ferric oxide sol and arsenious sulfide is due to the oxidation of the sulfide ion of the peptizing hydrogen sulfide by the ferric ion of the peptizing ferric chloride, the following experiment was performed.

Five hundred cc. of an arsenic trisulfide sol was precipitated with ferric oxide sol No. 4, the precipitate dried and extracted with carbon disulfide. Sulfur was recovered. Since arsenious sulfide sols are most likely to contain sulfur after exposure to air, a "blank" was run wherein an equal quantity of sol was precipitated by aluminum sulfate, the precipitate dried, extracted, and the sulfur found subtracted from that obtained in the main experiment.

It has been generally considered that hydrogen sulfide is always the stabilizing agent of arsenic trisulfide sols. In this investigation it was found that sols that contained an excess of arsenious acid, either through decomposing the arsenic trisulfide and driving out some hydrogen sulfide, or by failure to add an equivalent or slight excess of the hydrogen sulfide for the arsenious acid in solution when preparing the sols, were very stable. They gave a sharp range of precipitation with the ferric oxide sols, if sufficiently dilute, and acted in every way as did the arsenic trisulfide sols peptized by hydrogen sulfide. They have the advantage of having a nonvolatile peptizing agent, and one that does not oxidize as readily as does hydrogen sulfide, thus being more dependable for quantitative work. The arsenic trisulfide sols peptized by arsenious acid will probably be found more satisfactory for further quantitative work on the mutual precipitation of ferric oxide and arsenic trisulfide sols than those peptized by hydrogen sulfide have been.

Summary

- 1. The precipitating ratios of certain mutually precipitating hydrosols depend upon the peptizing agent.
- 2. There is chemical equivalence between the peptizing agents of ferric oxide hydrosol peptized by ferric chloride, and silicic acid sols peptized by sodium silicate, provided the ratio of peptizing agent to the dispersed phase falls within a certain range. Outside of this range the precipitation is erratic.
- 3. Ferric-oxide—silicic-acid sol precipitations showing chemical equivalence between the peptizing agents at maximum precipitation exhibit little variance in precipitation ratios with dilution, while those showing a divergence from chemical equivalence approach chemical equivalence with dilution.
- 4. Mutual precipitation of ferric oxide and silicic acid sols is due to the removal of peptizing agents by chemical reactions between them.
- 5. Qualitative experiment shows that the mutual precipitation of arsenious sulfide hydrosol and ferric oxide hydrosol may be due to the

chemical reaction $S^{--} + 2Fe^{+++} \longrightarrow S^{\circ} + 2Fe^{++}$. It was impossible to verify this quantitatively because of restrictions in the analytical procedures.

AZIDO-CARBONDISULFIDE. I. FORMATION, PREPARATION AND GENERAL PROPERTIES¹

By A. W. Browne, A. B. Hoel, G. B. L. Smith and F. H. Swezey With Microscopical Studies by C. W. Mason Received July 21, 1923

It was found by F. Sommer,² during an investigation of the properties of sodium azido-dithiocarbonate, that treatment of aqueous solutions of this salt with such oxidizing agents as ferric chloride, iodine in potassium iodide, and potassium permanganate, potassium dichromate, or ceric salts in sulfuric acid solution, results in the precipitation of an unstable white solid, surmised by him, from the method of its formation, to possess the formula N₂—N—CS—S—CS—N—N₂. No analysis was made of this compound, or study of its properties, aside from the observation that a sample of the insoluble needles, when heated under water, exploded violently at a temperature below 100°.

The formation of this substance, to which the name azido-carbondi-sulfide is provisionally assigned, has been repeatedly observed in this Laboratory³ to take place when aqueous solutions of potassium trinitride and iodine are brought together under certain conditions in the presence of carbon disulfide. Azido-carbondisulfide has been shown to have an important catalytic effect upon the reaction between potassium trinitride and iodine, as does the related compound, potassium azido-dithiocarbonate. In fact, these two substances, the relationship between which is very similar to that between iodine and potassium iodide, behave in this reaction in the manner characteristic of what might be termed a reciprocal catalytic pair.⁴

Formation and Preparation.—The action of various oxidizing agents

- ¹ The investigation upon which this article is based was supported by a grant from the Heckscher Foundation for the Advancement of Research, established by August Heckscher at Cornell University. The present paper is Article No. 4 under Heckscher Grant No. 4. For Articles 1, 2, and 3 see This Journal, 44, 2106, 2116, 2315 (1922). This paper was presented at the New Haven meeting of the American Chemical Society in April, 1923.

- ⁴ This term is intended to apply to any pair of chemical compounds that undergo repeated mutual conversion into each other while having their catalytic effect upon a given chemical reaction.

upon a 3% aqueous solution of potassium azido-dithiocarbonate has been investigated. Unless otherwise specified, a 1% solution of the oxidizing agent was gradually added in each case to 5 cc. of the azido-salt solution in a test-tube.

Hydrogen peroxide causes evolution of gas and produces a transitory, vellow-green color. The solution soon becomes turbid, and a considerable amount of azido-carbondisulfide is ultimately precipitated. Ozonized oxygen, when bubbled through the azido-salt solution, causes a slight evolution of gas. Potassium iodate and potassium chromate yield a small amount of precipitate after standing for several hours. With potassium persulfate, characteristic crystals of the azido-disulfide appear after a time. Mercuric chloride precipitates at once a heavy, white, crystalline substance, probably mercuric azido-dithiocarbonate, and later yields a fluffy, white precipitate of the azido-disulfide. In the presence of a slight excess of hydrochloric acid, ferric chloride first turns the solution red, and ultimately precipitates the azido-disulfide. Under similar conditions stannic chloride shows no action at first, but later forms a white precipitate. In the presence of sulfuric acid, potassium permanganate, solid manganese dioxide, solid cerium dioxide and sodium nitrite produce sooner or later the insoluble azido-disulfide, accompanied in the last case by evolution of considerable gas and appearance of a temporary brown color in the solution. Chlorine, bromine and iodine yield at once an abundant precipitate of the azidodisulfide.

Electrolysis of an approximately 20% solution of potassium azidodithiocarbonate between a rotating platinum anode of 30 sq. cm. total area and a stationary platinum cathode enclosed in a parchment thimble, with anode current density of 18.6 amp./sq. dm., resulted in the formation of relatively large amounts of azido-carbondisulfide, small particles of which occasionally exploded, under the solution, at or near the anode, with a sharp, crackling noise.

The method finally selected for the preparation of azido-carbondisulfide involves the following procedure.

Five cc. of the clear, concentrated solution of potassium azido-dithiocarbonate, obtained by filtering the liquid resulting from interaction of 6 g. of potassium trinitride and 6 g. of carbon disulfide in 25 cc. of water, is diluted with 50 cc. of water. Normal iodine solution in potassium iodide is added drop by drop, with continual stirring, until complete precipitation of the azido-disulfide has been effected. The slightest excess of free iodine must be avoided, however, as iodine appears to be adsorbed by the disulfide, and can be removed from it by washing only with some difficulty. If an excess of iodine be inadvertently added this may be reduced by addition of the requisite amount of a dilute solution of the azido-salt. The possible formation of an intermediate product such as iodine azido-dithiocarbonate, ISCSN₃, will be considered in a later investigation.

The precipitated azido-disulfide is washed in a Büchner funnel with cold water until free from soluble material, and is partially dried by suction. Small portions are carefully spread upon a porous plate with the aid of a bone spatula, avoiding tapping or undue

pressure, and are finally stored in a desiccator over phosphorus pentoxide, kept at 10° or lower, to minimize spontaneous decomposition.

Analysis.—Sulfur was determined in the thoroughly dried crystals of azidocarbondisulfide by oxidizing weighed samples with coned. nitric acid and bromine, and weighing the sulfur in the form of barium sulfate.

Analyses. Subs., 0.2251, 0.2002: BaSO₄, 0.8911, 0.7943. Calc. for $(SCSN_3)_2$: S, 54.27. Found: 54.37, 54.49.

Nitrogen was determined by combustion of the azido-disulfide in the manner already employed for potassium azido-dithiocarbonate.⁵

Analyses. Subs., 0.0567, 0.1890: N_2 , 16.12 cc. (0.02016 g.), 53.83 cc. (0.06733 g.). Calc. for $(SCSN_3)_2$: N, 35.57. Found: 35.56, 35.62.

These results point toward the formula suggested by Sommer for this compound and, in connection with the data concerning its decomposition submitted below, tend to confirm the following structure.

Properties.—Azido-carbondisulfide is a white, crystalline solid, soluble to the extent of about 3 parts in 10,000 of water at 25°. It is very unstable, and is distinctly more sensitive to impact and to heat than is potassium azido-dithiocarbonate. Explosions have frequently occurred at various stages of its preparation and investigation. These explosions result in the liberation of much heat, with more smoke but less flame than is characteristic of explosions of the azido-dithiocarbonate.

Three consecutive attempts to effect the slow, quantitative decomposition of weighed samples of the dry azido-disulfide, varying from about 0.06 to 0.17 g. in weight, by careful heating in a glass tube connected with a nitrometer, and immersed in a waterbath, resulted in violent explosions, in the first case at 54°, and in the second and third at 50°. Qualitative proof of the evolution of nitrogen and of the presence of thiocyanates in the residue and in the water above the mercury in the nitrometer tube was nevertheless obtained in the second experiment.

In a fourth experiment, 0.1097 g. of azido-carbondisulfide was held at 40° for 3 hours, with the result that 20.54 cc. (corr.) or 0.02569 g. of nitrogen, corresponding to 3.95 atoms of nitrogen per molecule of the disulfide, was liberated. Continued heating for a number of hours to an ultimate temperature of 60° increased the volume to 20.83 cc. (corr.) corresponding to 0.02605 g. of nitrogen, or 4.005 atoms of nitrogen per molecule of the compound.

Azido-carbondisulfide undergoes gradual spontaneous decomposition at ordinary room temperatures, with liberation of nitrogen, and formation of a solid residue probably consisting of a mixture of free sulfur and polymeric thiocyanogen,⁶ in accordance with the equation

$$(SCSN_3)_2 = 2N_2 + 2S + (SCN)_2$$
 (1)

A freshly prepared sample of the azido-disulfide weighing 0.1145 g. was placed in the nitrometer tube, which was immersed in a thermostatic

⁵ Browne and Hoel, This Journal, 44, 2315 (1922).

⁶ Söderbäck, Ann., 419, 217 (1919).

bath and held at 25° under close observation for a period of 72 consecutive The volume of nitrogen evolved was read at intervals of 1 or 2 hours. The data obtained are shown in Figs. 1 and 2.

These curves show clearly that the velocity of the decomposition, which has hitherto undergone a remarkably regular acceleration, begins to decrease as soon as two atoms, or 1/2 of the available nitrogen, has been evolved. This may indicate that the decomposition of azido-carbondisulfide takes place in two stages, with initial formation of an inter-halogenoid substance, azido-carbondisulfide thiocyanate, intermediate in

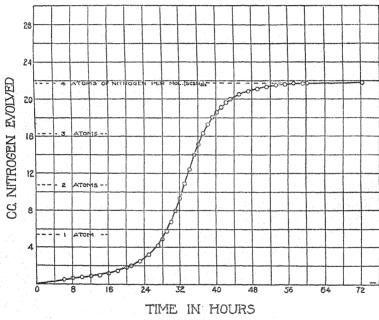

Fig. 1

composition between azido-carbondisulfide itself, and dithiocyanogen, in accordance with the equation

$$(SCSN3)2 = N2 + S + SCSN3.SCN$$
 (2)

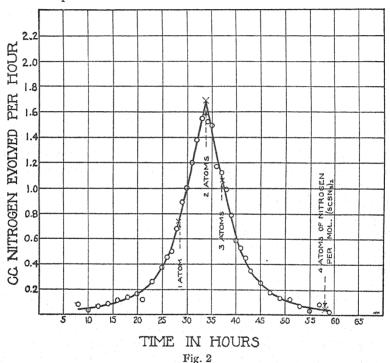

This intermediate product may then decompose more slowly, during the second stage of the reaction, as expressed by the equation

$$SCSN_3.SCN = N_2 + S + (SCN)_2$$
 (3)

During the decomposition of azido-carbondisulfide a very noteworthy change of color gradually takes place. In one experiment, typical of the many that have been performed, a sample of the pure white compound, after standing at room temperature (about 25°) for 23 hours, assumed a very light yellow color, YT2 on the Milton Bradley Standard.7 After

⁷ Mulliken, "Identification of Pure Organic Compounds," John Wiley and Sons. New York, 1st ed., 1905, vol. I, p. 232.

successive time intervals further changes in color resulted as follows: 4 hours, YT1; 16, OY; $3^1/2$, YO; $3^1/2$, O; 2, RO; $15^1/2$, RO-OS1; 7, OS1. The dark orange color thus attained, after a total period of nearly 75 hours, remains unchanged for an indefinite length of time. This series of changes seems to be in no way dependent upon the degree of illumination to which the material is subjected. One sample, exposed for some time to direct (July) sunlight, showed changes in color identical with those of a sample kept in a dark cupboard. The rate of change, however, varies directly with the temperature.

Under the microscope, crystals of the freshly prepared azido-carbondisulfide are seen to be colorless, and of tabular prismatic to acicular habit. For this reason end views are not obtainable. All prismatic views exhibit parallel extinction and fairly strong double refraction. The lower index of refraction corresponds to vibrations parallel to the elongation of the crystals. The mean index of refraction cannot readily be determined, on account of the solubility of the crystals in the various immersion liquids (essential oils), but it is estimated at about 1.8. The crystals show faces corresponding to the prism, bipyramid of a different order, and rarely the basal pinacoid. Tabular crystals, 6-sided in outline, exhibit terminal angles of about 138°. Asymmetric forms are frequent, particularly those in which 2 or 4 of the pyramid faces are not developed, giving rise to 5-sided or to trapezoidal outlines. At the ends of the crystals V-shaped markings are frequent. The habit and all observable optical properties lead to the classification of the crystals in the tetragonal or in the orthorhombic system.

When newly precipitated, dry azido-carbondisulfide is allowed to decompose at room temperature on a microscope slide, the crystals show surface corrosion after about 24 hours, and are coated with a yellow, viscous substance. Gas evolution takes place coincidently with a progressive corrosion or decomposition of the crystals from the surface inward, and not infrequently an isolated crystal is seen at this stage to be almost completely decomposed, a fragment remaining for a time imprisoned in the center of the viscous, amber liquid. Starting again at the outside, the decomposition product gradually becomes more viscous and also grows darker in color, yielding, in about 48 hours, after further evolution of gas, a reddish-orange, brittle, amorphous, vesicular mass, particles of which may retain something of the form of the original crystals. The final product, as seen by transmitted light, is of a somewhat greenish-yellow appearance in thin layers, while in thicker layers it is of a reddish-orange tint.

When a dried sample of the azido-disulfide is heated on a microscope slide it explodes, leaving an oily, viscous, yellow residue, apparently identical with the product of partial decomposition at room temperature. In case the detonation has been effected in such a way as to avoid heating of the slide, as by touching the sample for an instant with a hot platinum rod or wire, or by quickly passing a flame over it, the resulting liquid is of a very pale yellow color, and remains for some time entirely free from gas bubbles. If, on the other hand, the slide is heated, transformation of the yellow product into the usual brittle, vesicular mass, which would be formed in any event after the lapse of some time, soon takes place with comparatively rapid evolution of gas.

The yellow oil obtained as an intermediate product during the decomposition of azido-carbondisulfide is probably not identical with the amorphous thiocyanogen obtained, also in the form of a "clear, thick, yellow oil," by Söderbäck,8 but may consist of a solution of still unchanged azido-carbondisulfide in thiocyanogen, or of an inter-halogenoid compound, SCSN₃. SCN, as suggested in an earlier paragraph, mixed with free sulfur. Except for the presence of this free sulfur, the dark orange (OS1), brittle, vesicular product finally obtained, after further spontaneous liberation of gas from the yellow oil, is probably identical, however, with Söderbäck's "brick-red, light substance" obtained when the yellow oil was gently heated in a vacuum, or with his spontaneously formed "yellow-brown or yellow-red resin."

The yellow oil obtained as an intermediate product, either by spontaneous decomposition at room temperature or by careful detonation of azido-carbondisulfide, has been found to have a marked catalytic effect upon the decomposition of the disulfide. Freshly prepared samples of the oil, when brought into contact with undecomposed portions of azido-

⁸ Ref. 6, p. 237.

carbondisulfide, start at once a decomposition at a rate apparently equal to the maximum velocity of spontaneous decomposition at the temperature chosen. After the oil has itself undergone the second stage of decomposition, with formation of the resinous product, it loses its catalytic power.

As a result of the vesicular and resinous character of the decomposition product considerable difficulty was experienced in effecting a quantitative separation of the free sulfur from the polymeric thiocyanogen. Three methods were investigated: (1) prolonged heating of the mixture to 125°, until no further vaporization of sulfur takes place; (2) extraction with carbon tetrachloride; and (3) extraction with carbon disulfide. The last method yielded the best results. A sample of the dark orange mixture, weighing 3.6486 g., was extracted with carbon disulfide in a Soxhlet apparatus for a period of 100 hours, after which further treatment effected the separation of no additional sulfur.

The percentage of sulfur contained in the residue was determined, with the following results.

Subs., 0.4980, 0.4997: BaSO₄, 2.0065, 2.0188. Calc. for (SCN)_x: S, 55.21. Found: 55.33, 55.48.

These data indicate that the residue was a fairly pure, polymerized thiocyanogen. Further work upon this product will be carried on, in order to determine its molecular weight, and to investigate its properties and reactions.

Behavior toward Non-Aqueous Liquids.—Azido-carbondisulfide is appreciably soluble in methyl alcohol, ethyl alcohol, diethyl ether, carbon tetrachloride and xylene. It is moderately soluble in benzene and in carbon disulfide, and more readily soluble in ethyl acetate and in acetone. A sample weighing 0.1180 g., for example, was easily taken up by 1.4 cc. of acetone.

Solutions of azido-carbondisulfide in these liquids undergo gradual spontaneous decomposition at room temperature, with deposition of solids ranging in color from yellow to dark orange (OS1) and resembling in composition the residue obtained by decomposition of the solid solute. In some instances a secondary product is formed, probably as a result of the action of the freshly liberated thiocyanogen, SCN or (SCN)₂, upon the solvent. The velocity of decomposition is very much greater in some cases than that of the dry solute.

Xylene solutions show a slow evolution of gas almost at once, assume a yellow color, and soon begin to deposit droplets of a yellow, viscous substance. The final product possesses an odor closely resembling that of scorched rubber. Acetone solutions yield a dark orange (OS1) residue possessing a strong odor of garlic.

Behavior toward Acids.—Dil. sulfuric acid (1:6) shows little or no action upon azido-carbondisulfide at room temperature. At 40° the solid

slowly dissolves, and the resulting solution gradually becomes turbid owing to the liberation of sulfur. More concentrated acid (1:1) attacks the solid slowly even at room temperature, while the undiluted acid effects a more rapid reaction, accompanied by an appreciable evolution of gas.

Hydrochloric acid reacts with azido-carbondisulfide somewhat more readily than does sulfuric acid, with liberation of sulfur and evolution of gas. The residual solution obtained when concd. acid was used as the solvent was found to contain thiocyanates as well as an oxidizing agent capable of liberating iodine from a solution of sodium iodide. This action is attributable either to free chlorine, to thiocyanogen, or to an interhalogen-halogenoid compound such as chlorine azido-dithiocarbonate, CISCSN₃, or chlorine thiocyanate, CISCN.

Nitric acid in corresponding concentrations behaves in much the same way as hydrochloric acid, except that no precipitation of sulfur takes place. Acetic acid reacts somewhat less vigorously than the mineral acids, although the concd. acid promptly dissolves the solid azido-disulfide at room temperature, yielding a solution that is clear at first, but that becomes turbid after a time.

Behavior toward Alkalies.—Azido-carbondisulfide reacts at once with solutions of potassium hydroxide, yielding a clear, greenish-yellow solution. At room temperatures the liberation of small amounts of gas takes place immediately, and is followed by a very slow, long-continued evolution of gas as the unstable product is gradually decomposed. At low temperatures no perceptible evolution of gas occurs. For example, when about 3 cc. of a 10 N solution of potassium hydroxide was treated at —10° with the solid halogenoid, the usual greenish-yellow solution was formed, without liberation of gas. The reaction, in its initial stage, probably takes place in accordance with the equation

$$(SCSN_3)_2 + 2 KOH = KSCSN_3 + KOSCSN_3$$
 (4)

with formation of potassium azido-dithiocarbonate and potassium azido-oxydithiocarbonate, respectively, analogous to the chloride and hypochlorite formed by interaction of free chlorine and potassium hydroxide. Acidification of the greenish-yellow solution with dil. sulfuric acid in slight excess causes the precipitation of azido-carbondisulfide, as follows.

$$KSCSN_3 + KOSCSN_3 + H_2SO_4 = K_2SO_4 + (SCSN_3)_2 + H_2O$$
 (5)

This corresponds to the liberation of chlorine by acidification of a solution containing a chloride and a hypochlorite. The filtrate obtained on removal of the solid halogenoid was found to contain relatively large amounts of the azido-salt. This was shown by the abundant precipitation of azido-carbondisulfide that took place on addition of a solution of iodine, and by the vigorous catalytic action exerted by even a minute amount of the filtrate upon the reaction between iodine and potassium

trinitride. These point toward the conclusion that at least a part of the azido-dithiocarbonate, or hypochlorite analog, has undergone transformation to a derivative containing a larger amount of oxygen, such as the azido-trioxydithiocarbonate, or chlorate analog, as expressed by the equation

$$3 \text{ KOSCSN}_3 = 2 \text{ KSCSN}_3 + \text{ KO}_3 \text{SCSN}_3$$
 (6)

This chlorate analog may be regarded as a derivative of sulfuric acid obtained by replacement of an hydroxyl by the azido-thiocarbonyl group, CSN₂. On this assumption, the compound might easily hydrolyze in aqueous solution, especially after acidification with hydrochloric acid, yielding free sulfuric acid as one product. The presence of sulfuric acid in considerable amount has been established experimentally by repeated examination of the solutions obtained by interaction of azido-carbondisulfide and potassium hydroxide. 10 It is of course possible that the appearance of sulfuric acid may be due partly or wholly to the formation of potassium oxythiocyanate, KOSCN, by decomposition of the azidooxydithiocarbonate, and subsequent transformation of this hypochlorite analog of the thiocyanogen series to the chlorate analog, KO₃SCN, which in acid solution should hydrolyze, yielding sulfuric and hydrocyanic acids. Söderbäck,11 while apparently overlooking the analogy between cyanosulfuric and chloric acids, has demonstrated the formation of sulfuric and hydrocyanic acids as products of the hydrolysis of free thiocyanogen. The absence of hydrocyanic acid from the products of hydrolysis of azido-carbond sulfide, however, points toward the conclusion that the sulfuric acid is not in this case formed by way of the thiocyanogen derivatives, but that the new halogenoid probably forms its own series of oxyacids.

With solutions of sodium hydroxide, ammonium hydroxide, and sodium carbonate, azido-carbondisulfide was found to react as with a solution of potassium hydroxide, yielding the characteristic greenish-yellow solution.

Behavior toward Certain Oxidizing Agents and Reducing Agents.—Azido-carbondisulfide readily reduces potassium permanganate at room temperature in neutral, alkaline or acid solution. It reacts with potassium iodate in neutral and in acid, but apparently not in alkaline solution. A 3% solution of hydrogen peroxide slowly dissolves the disulfide, yield-

⁹ It has been found that potassium thiocyanate also has a marked catalytic effect upon the reaction between iodine and potassium trinitride, and it is thought that potassium thiocyanate and free thiocyanogen may, like potassium azido-dithiocarbonate and azido-carbondisulfide, constitute a reciprocal catalytic pair.

¹⁰ The experimental work on this topic has been performed in this Laboratory by Mr. Frank Wilcoxon, who first called attention to the presence of sulfuric acid among the products of this reaction.

¹¹ Ref. 6, p. 294.

ing a solution which has the odor of hydrocyanic acid.¹² The reaction seems to take place less rapidly in the presence of dil. sulfuric acid. The greenish-yellow color of the dilute alkaline solution containing sodium hydroxide is discharged by hydrogen peroxide, with evolution of gas.

Successive portions of azido-carbondisulfide added to a fairly concentrated aqueous solution of hydriodic acid cause immediate liberation of iodine, the color of which soon disappears, owing to a secondary reaction that possibly results in the formation of iodine azido-dithiocarbonate or iodine thiocyanate. Dilute aqueous hydrazine hydrate dissolves the disulfide at once, with slow evolution of gas, yielding a solution which is at first colorless, but later assumes a light greenish-yellow color (GYT2), and deposits a light gelatinous precipitate. Five per cent. solutions of ferrous sulfate, stannous chloride, and oxalic acid show no appreciable immediate reducing action upon azido-carbondisulfide.

Further work upon many of the topics briefly mentioned in the present article is now in progress in this Laboratory, and will be made the subject of future communications.

Summary

Azido-carbondisulfide, (SCSN₃)₂, a new halogenoid substance, has been prepared by chemical or electrochemical oxidation of potassium azido-dithiocarbonate, KSCSN₃, and its composition has been established by analysis. It is a white, crystalline solid, very slightly soluble in water, but readily soluble in certain non-aqueous liquids, such as acetone and ethyl acetate. It is stable at 0°, but undergoes quantitative autocatalytic decomposition at room temperature, yielding polymeric thiocyanogen, sulfur and nitrogen gas.

A preliminary study has been made of the behavior of azido-carbondisulfide toward acids and alkalies, and toward certain oxidizing agents and reducing agents.

ITHACA, NEW YORK

 $^{^{12}}$ Kastle and Smith $[Am.\ Chem.\ J.,\ 32,\ 376\ (1904)]$ have shown that thiocyanic acid is oxidized by hydrogen peroxide, with formation of sulfuric acid and hydrocyanic acid, probably in accordance with the equation, HSCN $+\ 3H_2O_2=HCN+H_2SO_4+2$ H_2O . The possible formation of cyano-sulfuric acid, the analog of chloric acid, as an intermediate product of this reaction, should be borne in mind. See also Bjerrum and Kirschner, Kgl. Danske Vidensk. Selskab. Math. Medd., [8] V, No. 1, 76 pp. (1918); C. A., 13, 1057 (1919).

THE RESISTANCE-TEMPERATURE COEFFICIENT OF CONCENTRATED SOLUTIONS OF POTASSIUM IN LIQUID AMMONIA AND THE SPECIFIC CONDUCTANCE OF SOLUTIONS OF POTASSIUM IN LIQUID AMMONIA AT INTERMEDIATE CONCENTRATIONS

By Charles A. Kraus and Walter W. Lucasse

RECEIVED JULY 23, 1923

In a preceding article¹ the authors have given the results of an investigation on the resistance-temperature coefficient of concentrated solutions of sodium in liquid ammonia. It appeared of interest to carry out a similar series of measurements with solutions of potassium in liquid ammonia at concentrations up to the saturation point. In the case of solutions of sodium in liquid ammonia, it was not possible to measure the temperature coefficient at lower temperatures over a considerable concentration interval, owing to the fact that this system separates into two phases with a critical point at -41.6° .²

The method and apparatus employed were the same as those previously employed in the case of sodium solutions. The results obtained, however, are on the whole more consistent than those obtained with sodium, partly because of the larger temperature interval which could be here employed and partly because of greater experience in the manipulation of the apparatus.

The Resistance-Temperature Coefficient of Potassium in Liquid Ammonia as a Function of Concentration.—Three independent series of measurements were carried out with solutions of potassium in liquid ammonia. Excepting the first two points in Series 1, the temperature interval employed was from the boiling point of liquid ammonia to -45° . The results are given in Table I, in which the dilution V, in liters of pure ammonia per gram-atom of potassium, is given in the first column; the upper temperature, in the second column; the lower temperature, in the third column; and, in the fourth column, the resistance-temperature coefficient:

$$\gamma = \frac{1}{R_{-33.5}} \frac{\Delta R}{\Delta t} \times 100.$$

The results are shown graphically in Fig. 1 in which the temperature coefficients are plotted as ordinates and the dilutions V, as defined above, as abscissas. The curve is similar to that obtained in the case of solutions of sodium in liquid ammonia, but is not identical with it. At the lower concentrations, the potassium solutions yielded a minimum coefficient of 1.42% as against 1.52% for sodium. At the higher

per degree, whereas that of sodium is approximately 3.6%. This difference may in part be due to the fact that the temperature interval in the case of the potassium solutions is markedly greater than in that of the

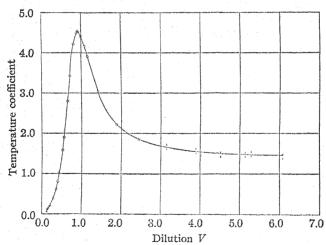

Fig. 1.—Variation of temperature coefficient of solutions of potassium in liquid ammonia as a function of concentration

sodium solutions; while at the same time the temperature coefficient increases with decreasing temperature. The maximum value of the temperature coefficient occurs at a dilution of approximately 1.15 liters in the case of sodium, while in that of potassium solutions it lies at a dilution of 0.91 liters.

Beyond the maximum, the temperature coefficient falls off very rapidly to a value of 0.0438% per degree for the saturated solution, which does not differ greatly from the corresponding coefficient of a solution of sodium. In the case of potassium, as in that of sodium, the coefficient would have a negative value if the concentration of the metal were slightly higher.

The Resistance-Temperature Coefficient as a Function of Temperature.—The resistance-temperature coefficient of solutions of potassium in liquid ammonia was measured at a series of temperatures down to approximately -70° for concentrations up to approximately normal. The results are given in Table II, in which the point in the series is given in the first column, the dilution V in the second column, the limits of the temperature intervals in the third and fourth columns, and the value of the coefficient γ in the last column.

Table II

Resistance-Temperature Coefficients of Potassium Solutions in Liquid Ammonia for Different Temperature Intervals

		40.0	50.0	5.30
		50.0	60.0	6.73
		60.0	70.2	7.29
	0.9120	33.0	45.0	4.55

The results here obtained are again similar to those obtained in the case of solutions of sodium. With decreasing temperature, the value of the coefficient increases. This is particularly marked at the higher concentrations, where the temperature coefficient increases approximately three times in passing from the interval of -32.9° to -40° to that of -60° to -67° . Very remarkable is the value which the coefficient assumes for the interval -60° to -70° , at a concentration in the neighborhood of the maximum, which amounts here to 7.29%.

Up to the present time it is not possible to indicate the factors to which the variation of the temperature coefficient may be due. It is a fact, however, that, at higher concentrations, the density of solutions of the alkali metals in liquid ammonia undergoes a phenomenally large change, the density increasing with decreasing concentration.³

The Specific Conductance of Solutions of Potassium in Liquid Ammonia at its Boiling Point at Intermediate Concentrations.—In an earlier paper the authors have given data on the specific conductance of solutions of potassium in liquid ammonia by direct comparison with mercury at dilutions as high as V=0.7229. Since that time a further series of measurements has been made carrying the dilution to V=1.597. The results are given in Table III, in which the dilution, as defined above, appears in the first row, and the specific conductance l in reciprocal ohms, in the second.

TABLE III

Specific Conductances of Solutions of Potassium in Liquid Ammonia at -33.5° V.... 0.3205 0.4031 0.4881 0.5782 0.7310 0.8893 1.240 1.597 1... 692.8 359.2 174.4 78.65 19.95 6.279 1.415 0.7470

The results of this series of experiments are in accord with those previously recorded and require no further comment. Attention should be called to a typographical error in an earlier paper, where the value of the equivalent conductance as given under Observation No. 1, in Table III, at dilution V=0.4229 should read "125,600.0." Calculating the value of the specific conductance of a lithium solution from this value, it is found to correspond very closely with the value for solutions of sodium and potassium at the same concentration.

Summary

The resistance-temperature coefficient of concentrated solutions of potassium in liquid ammonia has been measured from a dilution of 6 liters to the saturation point. The change of the temperature coefficient as a function of the concentration parallels that previously observed in the case of solutions of sodium. At higher concentrations, the temperature coefficient is somewhat greater for solutions of potassium than for sodium and the maximum temperature coefficient is found at a somewhat higher concentration.

The temperature coefficient has been measured as a function of the temperature at a number of concentrations. The temperature coefficient increases as the temperature decreases and the percentage change of the coefficient is greater at higher concentrations.

Some additional values are given for the specific conductance of potassium solutions in liquid ammonia at certain intermediate concentrations. These agree with previous observations.

³ Unpublished observations in this Laboratory.

A STUDY OF THE TERNARY SYSTEM, TOLUENE-ACETONE-WATER

By James H. Walton and John D. Jenkins RECEIVED JULY 23, 1923

Toluene and acetone are miscible in all proportions, as are also acetone and water. Water and toluene, however, are practically insoluble in each This investigation was undertaken for the purpose of determining the solubility curve for these three compounds.

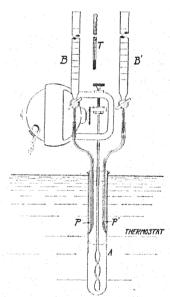

Reagents.-Acetone was dried over calcium chloride and fractionated, the fraction distilling between 56.05° and 56.16° at 760 mm. being used.

The toluene was dried over sodium, distilled and fractionated. The fraction boiling between 110.65° and 110.75° at 760 mm. was collected.

The water used was a high grade of conductivity water.

Apparatus and Method.—The pipets, burets and flasks were carefully calibrated with air-free water and the pipet also with toluene.

The apparatus in which the determinations were made is shown in Fig. 1. A is a 20 × 2.5cm. testtube in which the liquids were mixed; P and P' are two capillary delivery tubes, leading from the burets B and B' containing the acetone and one of the other liquids. The method of making a determination was A definite amount, usually 10 cc., of either water or toluene was pipetted into the testtube, which was then immediately stoppered, placed in the thermostat and allowed to stand for 15 minutes to come to the temperature of the bath. A small amount of the immiscible liquid, 0.2 to 0.5 cc., was then slowly added, the mixture vigorously stirred by means of the motor stirrer and acetone run in slowly, until the solution just cleared. The volumes of the Fig. 1.-Apparatus used for solliquids were then read and the temperatures of the burets noted. A new portion of the immiscible liquid

ubility determinations

was then added, and the process repeated. This was continued until the test-tube was about $^{2}/_{3}$ full, when another run was made in exactly the same manner, starting with the other immiscible liquid in the test-tube. This was found necessary because of the small solubility of one liquid in the other in the presence of a small percentage of acctone.

In order to obtain satisfactory determinations of the parts of the curves where there is only a small percentage of one component in the other (toluene in water, for example), it was found necessary to make a solution of this component in acetone, so that the volumes could be more accurately measured. For this purpose, a 20% solution in acetone was found convenient. The solution was made by weighing 20 cc. of the toluene into a 100cc. flask, filling to the mark with acetone and weighing again.

Because of the high coefficient of expansion of acetone, about 1.00145 per degree at 30°, great care was necessary to control the temperature of the solution. The flask was allowed to come to constant temperature in a thermostat for 15 minutes before it was finally made up to the mark. This solution, which was used in the buret instead of pure liquid, permitted accurate determinations down to about 0.05 cc. of one component in 10 cc. of the other.

The temperature of the liquids in the burets was taken as the average of several readings of the thermometer "T" during the run, the fluctuations usually not being more than a fraction of a degree. The temperature of the liquid placed in the tube was noted at the time it was added from the pipet and its weight and the weights of the others were calculated from their densities at their respective temperatures.

The end-point was taken as the point at which a bright object placed behind the test-tube became sharply defined. It was very sharp between the range of from 5% to 40% of water and especially between 5% and 15% of water. Between the range 15% to 30% of water, the mixture had a very decided colloidal appearance at the end-point, this effect being at a maximum with 20% water. The end-point was very distinct through this whole range, half a drop of acetone being sufficient to change the mixture from a distinct silky appearance, when rapidly stirred, to a distinctly cloudy, but transparent solution. Before adding the half drop, the mixture slowly separated into two layers, but afterward no separation occurred even on prolonged standing. On further additions of successive portions of acetone, the milkiness gradually disappeared, 0.5 to 1 cc. being required to make it disappear entirely.

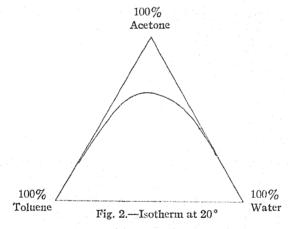

Data

Determinations were made at three temperatures: 0° , 20° and 30° . Four runs were made for each curve, first starting with 20 cc. of toluene in the tube and adding a 20% solution of water in acetone, and acetone, from the burets; second, with 10 cc. of toluene, adding water and acetone; third, with 10 cc. of water, adding acetone and toluene; and fourth, with 20 cc. of water, adding acetone and a 20% solution of toluene in acetone. These runs overlapped to some extent, the first extending from 0.5% water to 5% water, the second from 1.3% water to about 19%, the third from 17% water to 50% and the fourth from 47% water to about 80%. The parts of the curves overlapping checked very closely in all cases.

Table I Data for Equilibrium Line between the One-Liquid Phase and Two-Liquid Phase and Two-Liquid Phase Systems at 0°

		All percentages a	re by weight		
% Water	% Toluene	% Acetone	% Water	% Toluene	% Acetone

10.0	23.0	67.0	53.5	1.0	45.5
13.0	19.4	67.6 (max.)	61.0	0.5	38.5

Duplicate determinations were made on all runs at 0° and 20°, but not at 30°. The results of the duplicates checked very well with one another in every case. The data are given in Tables I, II and III. The data in Table II are shown diagrammatically in Fig. 2. The curves plotted from

the data in the other two tables are almost identical with the one in Fig. 2. The results in the tables are interpolated graphically to even percentages of water or toluene.

If the solubility surface in the composition temperature prism be drawn from the data of the three isotherms, it will be found that this surface rises abruptly from isotherm to isotherm. Temperature, therefore, has but little effect on the mutual solubility of the three components.

Attempts have been made by numerous authors to obtain mathematical expression for these curves, but with only moderate success. If the

can be fairly well expressed by the equation, $xy^n = \text{const.}$, in which x is the amount of one liquid, y the amount of the other and n a constant, depending upon the system and the temperature. This expression, however, is by no means exact. If we write the equation in logarithmic form, we have $\log x + n \log y = \log \text{const.}$ Differentiating we find, d $\log x + n \log y = 0$; or,

$$\frac{\mathrm{d}\,\log\,x}{\mathrm{d}\,\log\,y} = -\,n$$

Plotting $\log x$ against $\log y$ should give a straight line, if n is a constant. As a matter of fact, for this system the line is distinctly curved. Plotting y as the amounts of toluene and x as the amounts of water for a given weight of acetone, the curve is concave toward the $\log x$ axis. Other formulas have been suggested but none of them fits the curves satisfactorily.

Summary

- 1. The isotherm curves for the system, water-toluene-acetone, have been experimentally determined at three temperatures, 0°, 20° and 30°. An apparatus suitable for such determinations is described.
- 2. Temperature has but little effect on the mutual solubility of the three components.

MADISON, WISCONSIN

[Contribution from the Chemical Laboratory of Clark University, No. I, 30]

EQUILIBRIA IN SYSTEMS INVOLVING CALCIUM, HYDROGEN AND NITROGEN

By Charles A. Kraus and Charles B. Hurd Received July 26, 1923

The reactions of the more electropositive elements with hydrogen and with nitrogen and the interaction between the corresponding hydrides and nitrides, as well as the interaction of these compounds with nitrogen and hydrogen, possess considerable interest from the standpoint of the chemistry of nitrogen compounds. Up to the present time the available data are extremely meager. The present investigation was undertaken for the purpose of supplying further data in this field.

1. Action of Ammonia on Calcium and Barium Nitrides

Among the more recent and important investigations may be mentioned that of Mentrel,¹ who studied the reaction, $Ba(NH_2)_2 = Ba_3N_2 + 4NH_3$. He states that this reaction is reversible.

As is well known, calcium amide loses ammonia at higher temperatures and is ultimately converted to the nitride. Experiments were accordingly carried out in which the nitride was subjected to the action of ammonia in order to determine whether this reaction was reversible in the case of calcium.

Calcium amide was first prepared by treating the metal with liquid ammonia in a quartz tube in the presence of a trace of iron oxide, which served as catalyst. After vaporization of the excess ammonia, the resulting hexammoniate² was converted to the amide at temperatures slightly above that of the surroundings. The tube containing the amide was connected with a manometer, a vacuum pump, and a source of pure ammonia vapor. In a series of experiments, extending over a period of two months and at temperatures ranging from 200° to 850°, no indication of an equilibrium was observed. At higher temperatures, gradual decomposition of the amide took place with loss of ammonia and in the end there was left behind a yellow, porous material which consisted of calcium nitride.

¹ Mentrel, Compt. rend., 135, 740 (1902).

² Kraus, This Journal, 30, 653 (1908).

In view of the statement of Mentrel, the experiment was varied as follows. Ammonia was introduced into the system containing calcium nitride and measurements were made to determine whether any absorption took place either at a given temperature or on passing from higher to lower temperatures. In no case was such an effect observed.

To test these results further, metallic barium was treated in a similar manner. No indications of an equilibrium could be detected. Ammonia continued to be given off until only the nitride remained behind. On introducing ammonia gas into the tube containing the nitride, there was no indication of absorption at temperatures up to 850°.

Barium amide was also formed by passing ammonia over metallic barium. At 60°, a grayish deposit was observed on the surface of the metal which doubtless consisted of the amide. At 290°, this product melted, forming a dark gray liquid. At higher temperatures, this liquid became limpid and boiled vigorously, leaving behind a yellow solid. When this solid cooled, reliquefaction did not take place. This product was undoubtedly barium nitride. Experiments in which this nitride was treated with ammonia vapor gave no indications of reaction.

Our experiments, therefore, fail to confirm the observation of Mentrel and would appear to indicate that, under ordinary conditions, calcium and barium nitrides do not react with ammonia vapor.

2. Action of Nitrogen and Hydrogen on Calcium Hydride and Nitride, Respectively

Gautier³ studied the action of nitrogen on the hydrides of the metals of the alkaline earths and states that nitrogen may in part replace hydrogen in the hydrides at higher temperatures. Haber and van Oordt⁴ studied the action of nitrogen on calcium hydride and of hydrogen on calcium nitride. They state that the final product of the reaction of hydrogen on calcium nitride contains 15 parts of hydride per 100 parts of nitride, while the final product in the reaction of nitrogen with calcium hydride contains 10 parts of hydride per 100 parts of nitride.

Dafert and Miklanz⁵ have studied the action of hydrogen on the nitrides and nitrogen on the hydrides of the metals of the alkaline earths, as well as of mixtures of hydrogen and nitrogen on these substances. They have established the existence of compounds corresponding to the formula M₃N₂H₄, where M is an alkaline earth metal. The calcium and strontium compounds were obtained in a comparatively pure state. They established the formation of ammonia due to the action of hydrogen on barium nitride or, perhaps, Ba₃N₂H₄.

³ Gautier, Compt. rend., 134, 1108 (1902).

⁴ Haber and van Oordt, Z. anorg. Chem., 44, 340 (1905).

⁵ Dafert and Miklanz, Monatsh., 34, 1685 (1913).

Calcium hydride was prepared as follows. Calcium in the form of fresh filings was heated in a quartz tube through which purified hydrogen was passed. Reaction was found to take place readily at slightly elevated temperatures. The product first formed appeared somewhat yellow in color and was very brittle. This product was slightly grayish within, due, presumably, to the presence of a small amount of unchanged calcium, as was later confirmed by analysis. The initial product was pulverized and again treated with hydrogen, until a uniformly white product was obtained. This material contained a small amount of calcium oxide which, however, took no part in any subsequent reactions in which the hydride was involved. By rapidly handling it in a dry atmosphere the formation of oxide may be greatly reduced.

When nitrogen was passed over the hydride thus obtained, a gain in weight took place. The gain, however, was never found to be equal to the theoretical gain if complete conversion to nitride had taken place. This result was in part due to the fact that, at the temperature of the experiment calcium hydride is appreciably volatile as may be readily shown by heating calcium hydride in a stream of hydrogen.

In view of the uncertainty of the results derived from the weights of the substances involved in the reaction, analyses of the initial and final products were made. For this purpose a special apparatus was devised by means of which the product could be introduced into acidulated water and the amount of hydrogen evolved determined volumetrically.

The analyses of the original calcium hydride formed showed that this product contained over 90% of calcium hydride, CaH_2 . The remainder consisted chiefly of calcium oxide, due to the contact of the material with air. When this material was treated with nitrogen, the resulting product was found to contain less than 10% of calcium hydride.

On passing nitrogen over heated calcium, a product was obtained containing less than 6% of unchanged calcium. This material, heated to a very high temperature in hydrogen, increased in content of calcium hydride up to about 16%. Little increase above this percentage could be obtained. The temperatures required were in the neighborhood of 900°, under which conditions calcium hydride is comparatively volatile. At temperatures below 700°, calcium nitride, heated in hydrogen, gained in weight, probably due to the formation of an amide or imide.

3. Equilibrium in the System, Calcium Hydride, Calcium, Hydrogen

Measurements on this equilibrium were first carried out by Moldenhauer and Roll-Hansen⁶ who measured the equilibrium pressure of calcium hydride up to 1000° . They concluded that dissociation takes place in two stages according to the equations $CaH_2 = CaH + \frac{1}{2}H_2$, and CaH

⁶ Moldenhauer and Roll-Hausen, Z. anorg. Chem., 82, 130 (1913).

= $Ca + {}^{1}/{}_{2}H_{2}$. According to their determinations of the dissociation pressure of the sub-hydride, the equilibrium pressure is approximately ${}^{1}/{}_{2}$ that of the normal hydride. The above equilibrium was measured by Brönsted⁷ at lower temperatures and pressures. More recently the same equilibrium has been studied by Ephraim and Michel⁸ who virtually repeated the experiments of Moldenhauer and Roll-Hansen with somewhat divergent results. These earlier measurements will be discussed below.

Method and Procedure.—In view of the fact that the true equilibrium in this system may be obscured by certain sources of error, the method

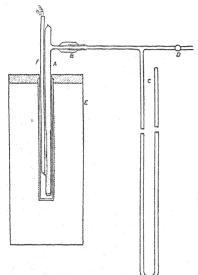

Fig. 1.—Apparatus employed in determining the dissociation pressure of calcium hydride

employed and the precautions observed will be described below in some detail.

The hydride was prepared from fresh filings of metallic calcium which were placed in a fused quartz boat in a horizontal Vitreosil tube, which was heated by means of a blast lamp. Pure, dry hydrogen was passed through the tube until tests showed that all air was displaced. The material in the boat was then heated to a moderate red heat, the current of hydrogen being regulated to compensate for the rapid absorption of gas which takes place under these conditions.

If calcium hydride, and to a lesser extent calcium itself, is heated to redness in contact with quartz, a certain amount of reaction takes place between the metal and the silica, wherein calcium oxide and silicon are formed. The reaction prod-

ucts, however, adhere to the walls of the silica boat and, if care is observed to remove the products without disturbing this coat, a pure calcium hydride may be obtained. From the silica boat the calcium hydride was transferred immediately into the measuring apparatus in which the equilibrium pressure of the hydride was determined.

The apparatus employed is shown in outline in Fig. 1.

The hydride was contained in a fused quartz tube A, of approximately 13 mm. internal diameter and 42 cm. length, closed at the bottom by means of a thick plug of fused quartz. The equilibrium chamber was joined to the remainder of the apparatus (constructed of glass) by means of a joint of de Khotinsky cement B.

At C is shown the manometer of the vacuum type. This manometer was checked from time to time against a high vacuum. Connection between the measuring system

⁷ Brönsted, Z. Elektrochem., 20, 81 (1914).

⁸ Ephraim and Michel, Helvetica Chim. Acta, 4, 907 (1921).

and the vacuum pump was made by means of the stopcock D. The equilibrium tube A was heated by means of an electric furnace E.

The temperature was measured by means of a platimum-platimum rhodium thermocouple F. The junction of the thermocouple was placed immediately against the quartz tube A at the point where the reacting material was located. The couple was calibrated before the experiments, by means of standard samples of lead, aluminum and copper, and at the end of the experiments it was checked against aluminum and found to have remained constant. The upper end of the furnace was closed by means of a plug of asbestos wool in order to minimize circulation. The temperature at different points within the furnace varied by less than 5°. All temperatures given were measured at the level at which the material was located in the quartz tube. The temperature was maintained constant by means of hand adjustment and ammeter control to within 1° between 600° and 1000°.

The greatest difficulty to be overcome in experiments with calcium hydride in quartz containers is due to the volatility of calcium hydride and its action on the quartz. Since hydrogen is evolved in this reaction, no determination of the equilibrium pressure can be made if the hydride is allowed to come in contact with the quartz container. This difficulty was somewhat troublesome in the earlier experiments and was finally overcome by placing the hydride in a tube constructed of pure iron and contained within the quartz tube A. The iron tube was of sufficient length to prevent the vapor of calcium hydride from coming in contact with the walls of the quartz tube.

The method of carrying out a series of experiments was as follows. Calcium hydride, prepared as described, was quickly mixed with about 1/2 its weight of fresh calcium filings, and placed in the iron tube. This tube was then allowed to slide to the bottom of the quartz tube A, the open upper end of which was then sealed off. The reaction tube was then quickly joined to the manometer system and immediately evacuated. By working rapidly and on days when the humidity was low, little change occurred in the hydride due to the action of moisture.

After exhausting the equilibrium chamber, the electric furnace was placed in position around the quartz tube, the thermocouple was introduced, and the furnace opening was plugged with asbestos wool. The temperature was then raised to approximately 800°, the system remaining attached to the pump. In this way any adsorbed gases were driven off. It was found that a certain amount of hydrogen was always evolved from calcium hydride made as above described, when heated to a temperature of from 300° to 400°. At higher temperatures this excess of hydrogen was reabsorbed by the excess of calcium present.

When all foreign gases had been removed from the system, the furnace was heated to about 970° and the temperature maintained constant. The pressure was then read at intervals until it reached constant value. A small amount of hydrogen was then withdrawn from the system by means of the vacuum pump and pressure readings were again taken until a constant value was reached. In this way equilibrium was approached from both sides.

After carrying out the measurement at a given temperature, the temperature was lowered and again maintained constant and pressure observations were made as before. This procedure was followed until a temperature was reached at which the rate of reaction was so low that measurements could not be made. The rate at which equilibrium is established varies greatly with the temperature. At 900° it was established in about 10 minutes, while at 600° approximately 10 hours was required.

Data.—The results of three independent series of measurements are given in the following table in which are given the temperatures at which

the pressure observations were made and the equilibrium pressures in centimeters of mercury as observed.

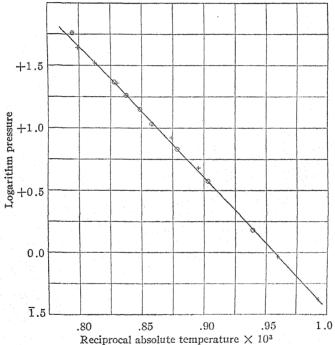

Fig. 2.—The dissociation pressure of calcium hydride as a function of the temperature

The results are shown graphically in Fig. 2, in which values of the logarithms of the pressures are plotted as ordinates against values of the reciprocals of the absolute temperature as abscissas.⁹ Points of Series 1

 9 The tangent to this curve at any point gives the value of H/R, where H is the energy change accompanying the reaction and R is the gas constant. If we write $\theta=1/T$, the reciprocal of the absolute temperature, then the differential equation of the curve is $\frac{\mathrm{d} \log K_p}{\mathrm{d} \Theta}=-\frac{H}{R}$.

are represented by combined crosses and circles, Series 2 by circles, and Series 3 by crosses. It will be observed that the points lie near a curve which closely approximates a straight line.

Discussion.—Assuming that hydrogen is the only constituent present in the reaction mixture whose pressure is appreciable, the pressure of the equilibrium mixture may be taken as a measure of the equilibrium constant. This assumption appears justified since no appreciable volatilization of materials was found to occur during the course of the experiments. Since the necessary thermal data for calculating the equilibrium constant at various temperatures are not known, the results obtained may be treated empirically. The best curve that may be drawn through the points deviates from a straight line by less than 1%.

Writing $\log P_{\rm H_2} = \frac{A}{T} + D$, where A and D are constants, and solving this equation for the values of the constants according to the curve, there is obtained the equation, $\log P_{\rm cm.} = -\frac{10.66 \times 10^3}{T} + 10.14$. This yields for the energy change accompanying the reaction the value 48400 calories.

Guntz and Bassett¹⁰ have determined the heat of formation of calcium hydride from its elements at ordinary temperatures and found it to be 46200 calories. Brönsted has also determined this quantity and obtained the value 45100 calories. The agreement of these values with that obtained from the curve cannot be looked upon as confirming the correctness of the results, since it is very doubtful that calcium hydride dissociates into hydrogen and metallic calcium. This is indicated, in the first place, by the results of Moldenhauer and Roll-Hansen, although their work is not altogether conclusive. Our own experiments would appear to indicate that metallic calcium could scarcely have been present in these experiments, since, according to Pilling, ¹¹ the vapor pressure of calcium is 0.173 mm. at 700° and 2.0 mm. at 805°, the melting point of calcium, while the boiling point lies at 1240°. With values of the vapor pressure of calcium of this order of magnitude, it is inconceivable that consistent measurements could have been obtained at temperatures approaching 1000°. ¹²

The determinations include three points at temperatures below the melting point of metallic calcium. The curve as drawn passes through these points and it does not appear that the precision of the measurements is

¹⁰ Guntz and Bassett, Compt. rend., 140, 863 (1905).

¹¹ Pilling, Phys. Rev., [2] 18, 362 (1921).

¹² This problem has been further studied by Mr. W. C. Johnson in this Laboratory. The volatility of calcium at temperatures in the neighborhood of 800° was confirmed. Furthermore, unquestioned evidence of the formation of a sub-hydride was obtained. While the normal hydride is white, the sub-hydride is dark gray to black in appearance. It appears to be much less volatile than calcium itself. The details of this work will be published later.

such as to warrant drawing the curve with an inflection point at the melting point. Nevertheless, it would be possible to draw a curve through the points for liquid calcium, which might be in somewhat better agreement with the determinations, by slightly reducing the slope of the curve at the higher temperatures.

The consistency of the results obtained in three independent determinations would appear to indicate that a true equilibrium exists in which calcium hydride and hydrogen are involved. While further evidence is desirable regarding the second solid phase present in the system, there can be little doubt that a sub-hydride exists as Moldenhauer and Roll-Hansen have suggested.

Our results are compared with those of earlier investigators in Fig. 4, in which the upper continuous straight line represents the results of this investigation and is identical with that of Fig. 2. The points determined by Moldenhauer and Roll-Hansen are represented by crosses, those determined by Ephraim and Michel by squares, while a few of the determinations of Brönsted are represented by double circles. The points represented by combined cross and circle, through which a broken line is drawn, represent Moldenhauer and Roll-Hansen's determinations of the sub-hydride equilibrium.

It will be seen that the determinations of Moldenhauer and Roll-Hansen are subject to very large variations. The lowest point falls very nearly on our curve, while at intermediate temperatures the points lie much above our curve. At higher temperatures the curve determined by these investigators again crosses our own and at the highest temperatures lies considerably below it. The determinations of Ephraim and Michel are inconsistent with both our own determinations and those of Moldenhauer and Roll-Hansen. The values determined by Brönsted lie considerably above our curve. An examination of Brönsted's data shows that his curve is markedly concave toward the axis of reciprocal temperatures, indicating, if the results are correct, that the energy change accompanying the formation of the hydride from its elements, or from a lower hydride, diminishes markedly with increasing temperature. Brönsted has proposed an equation for the curve which accounts for his values very satisfactorily on the assumption that, as he states, the sum of the heat capacities of calcium and hydrogen is 4.2 calories greater than that of the hydride. This, however, would correspond to an increase and not a decrease in the value of the energy change with increasing temperature. To account for a decrease, it would be necessary to assume that the heat capacity of the hydride is greater than that of the sum of the constituents from which it is formed, which assumption does not appear probable. As Lewis and Randall have pointed out,13 at higher temperatures, the difference in the

¹³ Lewis and Randall, "Thermodynamics," McGraw-Hill Book Co., N. Y., 1923, p. 472.

heat capacities is probably very small, and it is not to be expected that the curve will deviate from a straight line sufficiently to become observable over a temperature interval of a few hundred degrees. Probably the form of the curve as found by Brönsted is due to undetermined sources of experimental error.

The broken line passing through the points represented by combined cross and circle represents Moldenhauer and Roll-Hansen's determinations of the equilibrium pressure of the sub-hydride. While these points lie consistently on a straight line, the curve passing through the points intersects our curve for the dissociation of the normal hydride and would also intersect a curve drawn through the points determined by Moldenhauer and Roll-Hansen for the same equilibrium. This throws doubt on the interpretation of the observed results. Subsequent measurements in this Laboratory, referred to in a preceding footnote, indicate that the dissociation pressure of the sub-hydride is exceedingly low, if measurable, at a temperature of 790°. While a sub-hydride in all probability exists, it must be assumed that any measurements of its dissociation pressure cannot be relied upon at the present time. Metallic calcium is so volatile at the temperatures in question that erroneous results may easily be obtained, due to the fact that the metal distils from the hotter to the cooler portions of the tube, under which conditions the normal hydride may conceivably be formed, yielding pressures commensurable with, but lower than those of the normal hydride at the true temperature.

4. Equilibrium in the System, Calcium Nitride, Calcium, Nitrogen

The nitrides of the metals of the alkaline earths possess a much greater stability than the corresponding hydrides. The formation of the nitrides through the action of nitrogen on the metals, however, takes place much less readily than does the corresponding formation of the hydrides. Moissan¹⁴ has studied the formation of nitrides from the elements, as well as the rate of formation and the influence of impurities.

The formation of barium nitride from barium and ammonia with the intermediate formation of barium amide has been studied by Mentrel. He showed that the nitride vaporizes appreciably at 1000°, but apparently exhibits no marked dissociation at that temperature. He also determined the heat of formation of barium nitride. Gautier³ has observed that the nitrides of barium, calcium, and strontium are dissociated to a much smaller extent than are the corresponding hydrides.

The heat of formation of calcium nitride has been determined by Guntz and Bassett, ¹⁰ who obtained the value 112,200 calories per mole. This is comparable with the heat of formation of some of the more stable com-

¹⁴ Moissan, Compt. rend., 127, 496 (1898); Ann. chim. phys., 18, 289 (1899).

¹⁵ Mentrel, Dissertation, Nancy, 1902; Chem. Zentr., 1903, I, 276.

pounds of calcium, and indicates that the stability of the nitride is relatively high.

In addition to the above-mentioned methods of preparing the nitrides, some others, less common, have been employed. Thus Ellis¹⁶ heated the oxide of the metal with magnesium in an atmosphere of nitrogen, while Wolk¹⁷ heated barium amalgam in nitrogen.

The formations of the nitrides of barium, strontium and calcium have also been studied by Dafert and Miklanz.⁵

Previous investigations have indicated that the nitrides are extremely stable substances, but no data are available as to the temperature at which the dissociation pressure might become appreciable. In view of the volatility of the nitrides, as well as of the metals themselves, it appeared impracticable to study these systems at temperatures much above 1000°, and accordingly little hope was entertained that accurate measurements might be obtained on the dissociation pressure of the nitrides. Nevertheless, it appeared of interest to study the order of magnitude of the dissociation pressures in these regions if possible.

Method and Apparatus.—The apparatus at first employed was similar to that used in the determination of the dissociation pressure of calcium hydride, shown in Fig. 1.

Calcium nitride, prepared from calcium filings, was mixed with about half its weight of fresh calcium filings and placed in an iron tube which was introduced into the quartz tube A. Although this was heated to over 1000° , no pressure could be observed on an ordinary vacuum manometer. The apparatus was accordingly modified so that the pressures could be read by means of a sensitive McLeod gage. With this gage, pressures could be accurately read between 0.1 and 0.001 cm. of mercury, and lower pressures could be approximated within 1×10^{-5} to 5×10^{-5} cm., depending upon the value of the pressure.

It was soon found, with the use of this gage, that the apparatus employed was not sufficiently tight to maintain the necessary high vacua. Accordingly, a mercury trap was introduced into the system between the apparatus and the stopcock connecting the apparatus with the vacuum pump. This trap was constructed in the form of a Y, the lower branch of which was connected with a mercury reservoir, by the elevation of which the connection between the apparatus and the stopcock could be closed.

It was found, as a result of experiment, that the tube A, which had originally been constructed of Vitreosil, was not sufficiently tight to permit accurate measurements to be made. Accordingly, it was replaced by a tube constructed of clear quartz. With this alteration, the system remained sufficiently tight to allow such measurements to be made. In the course of 72 hours, the pressure change observed amounted to 8×10^{-5} cm. The residual pressure in the system was measured before and after each series of observations at a temperature of 850°. The following values were obtained; before the first series, 6×10^{-5} cm.; between the first and second, 7×10^{-5} cm.; between the second and third, 8×10^{-5} cm.; and at the end of the third, 11×10^{-5} cm. The last pressure was measured at 950°. It was assumed that the true pressure of the nitrogen could be obtained by subtracting the pressure of the residual gases from the observed

¹⁶ Ellis, Chem. Zentr., 1909, I, 900.

¹⁷ Wolk, ibid., 1910, II, 1442.

total pressure. In general, the final rather than the initial pressure was assumed to give more nearly the correct value.

In carrying out a series of measurements, the furnace was slowly brought to a temperature of 1050°, and then allowed to cool slowly. The temperature and pressure were read at intervals. It was observed, during the first series, that a small amount of calcium had distilled into a region slightly above the point where the quartz tube extended out of the furnace. It was impossible to avoid this difficulty, but by working as indicated the effect was minimized as much as possible. The distillation of the calcium or some other product from the warmer to the cooler portion of the tube, however, may have had an appreciable influence on the measurements, since the equilibrium as measured may not have been that of the hottest portion of the tube, where the temperature was read. In the initial experiments, where the distillation process had not proceeded far, this factor was perhaps of little influence; but in succeeding experiments with the same sample of material the pressures as measured were doubtless somewhat lower than the true ones.

The results of three series of measurements made with the same sample are given in Table II. The results of the first run are undoubtedly more

reliable than the succeeding ones, in view of the distillation of the calcium from the hotter to the cooler portions of the tube, as just mentioned. In the first column is given the temperature on the centigrade scale and in the second column the observed pressure. In the third column, in the

first series of experiments, is given the observed pressure, corrected for the pressure of the residual gas, here assumed to be 7×10^{-5} cm.; and in the last column is given the calculated pressure according to an empirical equation.

If the logarithms of the pressures are plotted against the reciprocals of the absolute temperatures, the points should lie approximately on a straight line if the pressures measured represent true equilibrium pressures. When the observed pressures are plotted in this way, it is found that a curve results which is markedly convex toward the axis of reciprocal

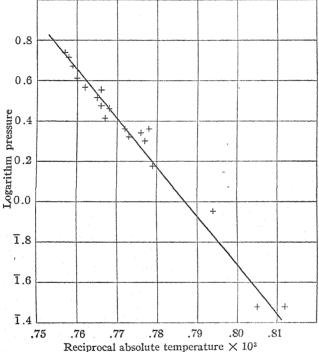

Fig. 3.—The dissociation pressure of calcium nitride as a function of the temperature

temperatures. When, however, the corrected pressures are similarly plotted, the points lie upon a straight line within the limits of the experimental error. The curves obtained for the three series of measurements do not coincide, although they run parallel with one another. Apparently, in succeeding experiments, the curves are displaced toward lower temperatures. This is doubtless due to the distillation of material from the hotter to the cooler portions of the tube, the temperature of the equilibrium mixture thus being lower than the temperature as measured.

In Fig. 3 the logarithms of the corrected pressures for the first series of

experiments are plotted as ordinates against the reciprocals of the absolute temperatures as abscissas. As may be seen from the plot, the points lie upon a straight line within the limits of the experimental error. The greatest deviations are observed at relatively low pressures, where the precision of the measurements is lowest. For the three points at the lowest pressures, the deviations reach a value of approximately 25%. For the remaining points, the deviations do not exceed 10% and for the most part are less than 5%. Considering the values of the pressures and the conditions under which the experiments were carried out, it would seem that, at the higher pressures and temperatures, the agreement is reasonably satisfactory. The straight line as drawn on the plot corresponds to the equation, log $P_{\text{cn}_L} = -\frac{24.36 \times 10^3}{T} + 15.166$. This yields for H, the energy change of the reaction per mole of nitrogen, the value 113,250 calories, which corresponds very closely with the heat of formation of calcium nitride as determined by Guntz and Bassett. It is doubtful, however, whether tais agreement can be looked upon as a confirmation of the results obtained, inasmuch as it is extremely doubtful that metallic calcium is here involved in the equilibrium. At the temperatures in question and with the low pressures existing in the apparatus, any free calcium present mus have vaporized into the cooler portions of the tube, probably to regions here the temperature would be little in excess of 700° or 70-50°. The fact hat a fairly good agreement is obtained among the different posints of given series would appear to indicate the existence of a definite equilibitum and it is possible that, in the case of calcium nitride, a sub-nitride myay be formed corresponding somewhat to the sub-hydride, as pointed out in the preceding section. In any case it may be concluded that realcium nitride is an extremely stable compound.

Equilibrium in the System Calcium, Hydrogen, Nitrogen, Calcium Nitride, Calcium Hydride, and Reaction Products

The results presented in Section 2 indicate that reaction takes place between hydrogen and calcium nitride and between nitrogen and calcium hydride. It was, therefore, decided to determine, if possible, whether equilibria exist in the system composed of calcium hydride, calcium, calcium nitride and hydrogen.

The apparatus employed was similar to that shown in Fig. 1, except that a side tube of quartz was connected to the tube A and provided with a small heating furnace. A palladium tube was introduced, closed at the end and sealed through a glass tube by means of a short length of platinum tubing. The end of the palladium tube was placed within 2.5 cm. of the tube A within the auxiliary furnace. The glass tube, into which the palladium tube was sealed, was connected with a manometer and a source of

hydrogen. When the palladium tube was heated by means of the auxiliary furnace, diffusion of hydrogen took place, either into or out of the system, depending upon the pressure. If any gas other than hydrogen were present in the reaction tube, its partial pressure could be determined by comparing the pressures indicated by the manometer connected to the reaction tube A and that attached to the palladium diffusion tube. Both the original reaction tube and the diffusion tube were provided with connections to sources of hydrogen and of vacuum.

A freshly prepared mixture of calcium hydride, calcium nitride, and calcium filings was introduced into an iron tube which was then sealed into the reaction tube A. The ingredients were quickly mixed before introduction into A and the subsequent operations were carried out as quickly as possible in order to minimize the influence of the atmosphere.

After introduction of the materials into the reaction tube the system was heated and pumped out, after which the equilibrium pressures were measured at a series of temperatures. The following values were obtained.

TABLE III

Dissociation Pressures in a Mixtur	E OF CALCI	um Hydridi	e, Nitride	and Calcium
<i>i</i> °C	1008.1	969.3	882.1	812.5
P cm. Hg	45.70	23.80	6.26	1.51

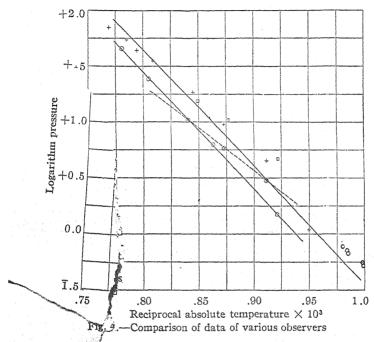

The gas present was evidently pure hydrogen, since the pressure readings on the two manometers were equal. Equilibrium was established very quickly and was approached from both sides, so that there can be no question but that the pressures read represented equilibrium pressures.

After the above series of readings had been made, the temperature was kept at 870° for several days and hydrogen was removed several times a day. After some days it was observed that the pressure was falling slowly from a value of 4 cm., although no hydrogen was being removed at the time. This continued until the pressure became so low that it could not be read on the manometers. When the temperature was raised to 1030°, no indication of evolution of gas was observed.

On readmitting hydrogen into the system through the palladium tube, rapid absorption took place. Unfortunately, it was found necessary to discontinue the investigation at this point.

The results are shown graphically in Fig. 4, in which the logarithms of the observed pressures are plotted as ordinates against the reciprocals of the absolute temperatures as abscissas. The points are represented as circles and a continuous straight line is drawn through them. The consistency of the values obtained would appear to indicate that a true equilibrium of some kind was measured. It will be noted that the curve is very nearly parallel with that of the calcium hydride equilibrium, which is represented by the upper continuous straight line. It is possible that a

portion of the calcium distilled from the hotter to the cooler portions of the tube and that the equilibrium represents the equilibrium of calcium hydride, the temperature being in error, due to the distillation effect. This would not, however, account for the rapid absorption of hydrogen in the later

stages of the experiment. Furthermore, a consistent series of pressure readings extending over a considerable period of time would not be expected under these conditions.

Summary

The action of ammonia on calcium and barium nitrides has been investigated. Contrary to the statement of Mentrel, no indications of absorption of ammonia by these nitrides could be observed.

Calcium hydride, treated with nitrogen, yields an end product containing less than 10% of hydrogen, and calcium nitride treated with hydrogen yields a product containing approximately 16% of hydrogen.

The dissociation pressure of calcium hydride has been measured at a series of temperatures. The results indicate the existence of a definite equilibrium involving hydrogen and calcium hydride. The third phase is uncertain, but the conditions of the experiment together with the observations of earlier investigators render it probable that a sub-hydride of calcium exists. The results obtained are compared with those of earlier investigators.

An attempt has been made to measure the dissociation pressure of calcium nitride at temperatures somewhat above 1000° . Reproducible pressure readings were obtained of the order of magnitude of $0.3\text{--}5.5 \times 10^{-4}$ cm. The results are consistent with an energy change accompanying the reaction of 113,250 calories, which agrees well with the heat of formation of calcium nitride at ordinary temperatures, as determined by Guntz and Bassett. It is pointed out that in all probability calcium could not have been present as a third phase in this equilibrium.

In a system consisting initially of a mixture of calcium, calcium nitride and calcium hydride, an equilibrium was found to exist at temperatures in the neighborhood of 1000°. Only hydrogen was present in the vapor phase. After continued heating at 870°, the hydrogen was ultimately completely absorbed.

A PHOTOCHEMICAL STUDY OF ACETYL-CHLORO-AMINOBENZENE¹

By J. H. Mathews and R. V. Williamson Received July 26, 1923

In connection with a series of investigations which were being carried out in this Laboratory, there was needed a light sensitive compound whose changes could be easily and accurately followed. The compound, acetyl-chloro-aminobenzene, appeared to be one that might serve the purposes for which these compounds were wanted.

Blanksma² appears to be the first to have noted that the compound was sensitive to light and he stated, "The reaction is much accelerated by light and it appears to be a general rule that the radicals Br, Cl, NO₂, NO and O attached to nitrogen, change places, under the influence of sunlight, with an H atom in the nucleus."

Chattaway and Orton also made some velocity measurements on the transformation of the compound in sunlight.³ But there appears to have been no study made of the effect of light on the transformation of the compound under conditions such that the light intensity and conditions of the experiments were under control. Therefore, the present investigation was undertaken for the purpose of obtaining velocity measurements under conditions which could be duplicated.

¹ This paper constitutes the major part of a thesis submitted by R. V. Williamson in partial fulfilment of the requirements for the degree of Master of Science at the University of Wisconsin.

² Blanksma, J. Chem. Soc., 82, 646 (1902); Rec. trav. chim., 21, 290 (1902).

³ Chattaway and Orton, Proc. Chem. Soc., 18, 200 (1902).

The compound has attracted considerable attention in connection with the theory of solutions. With dil. hydrochloric acid the compounds R.CO.NR'Cl undergo a molecular rearrangement in which the chlorine attached to the nitrogen exchanges places with one of the hydrogen atoms of the benzene ring. This reaction may be represented as follows: CH_3 - $CONClC_6H_5 + HCl = CH_3CONHC_6H_4Cl + HCl$.

From this equation, it is apparent that the hydrochloric acid acts as a catalyst, as the only change in the substances present has been a molecular rearrangement of the acetyl-chloro-aminobenzene to chloro-acetanilide. The above reaction is a monomolecular reaction in the presence of dil. hydrochloric acid but does not follow the monomolecular equation at higher concentrations of acid. It follows the equation for a bimolecular reaction in the presence of hydrobromic acid. These data have led Acree, Senter⁵ and others to propose the "Dual Theory" of reaction in solution, that is, both ions and molecules react when a reaction takes place in solution.

Harned and Sethz have opposed this "Dual Theory" and have shown that the velocity of rearrangement of acetyl-chloro-aminobenzene to p-chloro-acetanilide by hydrochloric acid is proportional to the product of the hydrogen and chlorine ions.⁶

In view of the theoretical importance of the catalytic reactions which this compound unsergoes in the dark it may be of interest to present the data obtained in agard to its behavior under the influence of light from a quartz mercury—por lamp in different solvents and under various conditions.

Preparation and Purification of Chemicals Used

The acetyl-chloro-aminobenzene was prepared by Slosson's method. The melting point of the compound was 89°. All chemicals used were prepared by purification of the standard brands of c. p. materials.

Apparatus

A quartz mercury-vapor lamp of a common commercial type was used as the source of illumination. On each side of the lamp was placed a quartz flask for holding the solution to be examined. All flasks were of the same size and each flask was provided with a mechanical stirrer which operated from the same pulley so as to produce the same agitation in each flask. A thin sheet of water flowed from the constant-temperature reservoir over the surfaces of the flasks to maintain them at the desired temperature. The electrical circuit was provided with a variable resistance for controlling the current passing through the lamp. The apparatus was set up in a dark room and all the work connected with the experiments was done in the dark room, with the help of electric lights.

⁷ Slosson, Ber., 28, 3265 (1895).

Procedure

By trial experiments the exact position of the flasks, with respect to the light, necessary to produce duplicate results when portions of the same solution were placed in each flask was determined. The flasks were then marked and the necessary measurements made to allow them to be removed from their clamps and replaced in exactly the same positions. They were filled with definite amounts of the solution to be examined, the stirrers started, the water for controlling the temperature was turned on, a light shield inserted between the light and the flask and then the current was turned on the lamp. When the lamp had reached its maximum intensity, a sample of 2 cc. was removed from the 100cc. flask for the initial titration, and then the light shield was removed. At definite time intervals other samples were removed for titration. A check was always carried on at the same time, to determine the velocity of the dark reaction, by means of a similar flask painted with asphaltum varnish to protect the solution from the light. The velocities of the reactions of two different solutions were compared by placing one solution in Flask 1 and the other in Flask 2.

The course of the reaction was followed by titrating with sodium thiosulfate solution the iodine liberated when the sample was allowed to run into an excess of potassium iodide acidified with hydrochloric acid. The acetyl-chloro-aminobenzene liberates iodine from a potassium iodide solution acidified with hydrochloric acid, whereas the transformation product, p-chloro-acetanilide does not.

The temperature of the water flowing over the flat impound, acetylmeter and ammeter readings were recorded after each he purposes for following is a typical example of the method of recording shows the variation in temperature and voltage during an expension was

		TABLE I							
	TYPICAL DATA								
Time	Volts	Amps.	Temp.	Na ₂ S ₂ O ₂ Cc.					
9.25	67	3.0	21.0	8.70					
9.40	66	3.05	21.4	7.55					
9.55	65.5	3.1	20.9	6.45					
10.10	68	3.05	20.6	5.40					
10.25	68	3.1	20.6	4.28					
10.40	69.5	3.1	20.7	3.20					
10.55	65	3.1	20.9	2.35					
11.05	69	3.1	20.7	1.90

11.30	70	3.1	20.7	1.20					
11.40	68	3.1	20.9	1.10					

This is a fair example of the variation in voltage and temperature but the amperage is an average reading of the ammeter. The amperage remained constant for the most part at the point indicated, but occasionally showed temporary fluctuations of ± 0.2 ampere.

Three experiments are recorded below showing the velocity of the dark reaction when the compound was dissolved in dil. acetic acid, and the degree of accuracy obtainable when portions of the same solution were placed in each flask.

Expt. 1.—1.6950 g. of acetyl-chloro-aminobenzene was dissolved in 100 cc. of glacial acetic acid and diluted to 1 liter with distilled water. The solution was kept in a brown bottle which was placed in the ice chest with cracked ice surrounding it. We shall call this "Solution A." Samples of Solution A were titrated from time to time to get the velocity of transformation in the dark.

$Na_2S_2O_3$, cc	19.77	19.64	19.49	19.33	19.13

Expt. 2.—Expts. 2 and 2' were made to show that the two flasks were so adjusted that the velocity of the reaction was the same when they contained portions of the same solution. The solution in this experiment was made by taking 90 cc. of Solution A and diluting it to 180 cc.

These experiments show that the reaction follows the equation for monomolecular reactions in dil. acetic acid solution under the influence of light, which is characteristic of photochemical reactions. When the compound was dissolved in other solvents, however, it was not always possible to calculate the velocity constant.

Experimental Part

In Fig. 1, Curves I and II compare graphically the velocities of reaction for two solutions of 0.01~M acetyl-chloro-aminobenzene in 10% acetic acid solution plus 2% sodium acetate and in 10% acetic acid alone, respectively, when exposed to ultra-violet light. The curves show that practically no effect was produced by the addition of the sodium acetate. The velocity constants calculated by the equation for monomolecular reactions were 0.0064 and 0.0067; the difference is within the experimental error.

Curves III and IV, Fig. 1, are duplicate determinations for the same strength, and under the same conditions as Curves I and II, except that benzene was used as the solvent.

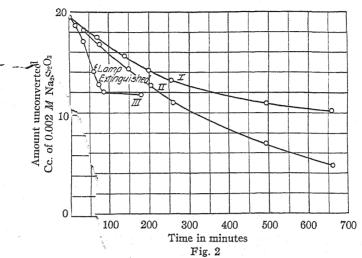

Curve V, Fig. 1, is a duplicate of Curves III and IV except that the benzene used as a solvent was recovered from the solutions used in producing Curves III and IV. The benzene was recovered by distilling it from the solute. Evidently some compound distilled with the benzene which catalyzed the reaction and speeded it up to a very marked degree. No effort was made to determine the exact reason for this behavior.

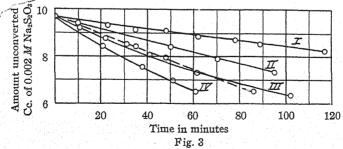

Curves I and II, Fig 2, show the relative transformation of a $0.01\ M$ and $0.02\ M$ solution in 10% acetic acid under the influence of light of the same intensity. While the stronger solution showed a slightly greater amount transformed in unit time, the velocity constant was only 0.0009 as compared with 0.0017 in the more dilute solution. That is, the velocity constant for the solution of double strength had a value of one-half that for the more dilute solution.

Curve III, Fig. 2, shows the comparative amount transformed when the solvent is glacial acetic acid as compared to 10% acetic acid in Curves I and II. It shows also that the reaction continues with practically no change in velocity when the light is extinguished. This solution in glacial acetic acid showed no change during a period of one-half hour previous

to turning on the light. However, when the light once initiated the reaction, it proceeded without diminution when the light was extinguished. This was found to be true in other solutions where water was absent.

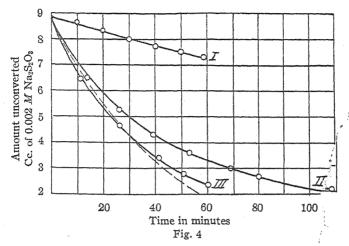

In view of the fact that hydrochloric acid catalyzes the transformation in the dark it was thought that perhaps the reaction would be extremely sensitive in the light in the presence of this acid. Curve I, Fig. 3, shows the mount of transformation of a 0.01 M solution in 10% acetic acid containing 45% N hydrochloric acid in the dark as compared with the light reaction in 10% acetic acid in Curve II, the light reaction in 10% acetic acid plus 25% of N hydrochloric acid in Curve III and to the light reaction of 10% acetic acid containing 45% of N acid in Curve IV. The broken line

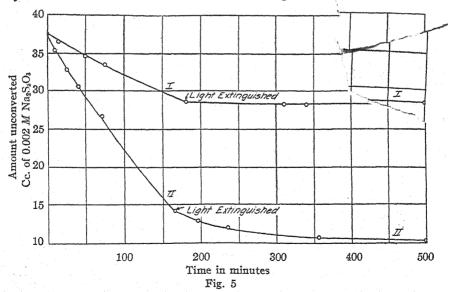

curve represents the sum of the dark reaction in the presence of 45% of N hydrochloric acid plus the light reaction in 10% acetic acid. This indicates that the light reaction in the presence of hydrochloric acid is greater than the sum of the light reaction in dil. acetic acid plus the dark reaction produced by hydrochloric acid.

Curve I, Fig. 4, shows the transformation in 10% acetic acid under the

action of light compared with the dark reaction in 10% acetic acid plus 2% of 0.25~N hydrobromic acid as shown in Curve II, and the light reaction

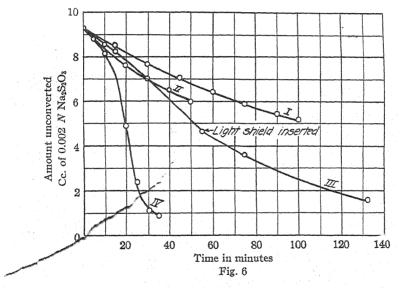

in 10% acetic acid plus 2% of 0.025~N hydrobromic acid, Curve III. The broken line represents the sum of the individual reactions represented by Curves I and II. From these results the light reaction in 10% acetic

acid solution containing 2% of 0.25~N hydrobromic acid is shown to be practically equal to the sum of the light reaction in 10% acetic acid plus the dark reaction produced by the presence of the hydrobromic acid in the 10% acetic acid solution.

Curve I, Fig. 5, shows the result of illuminating with ultra-violet light a 0.04~M solution of acetyl-chloro-aminobenzene in 10% acetic acid in comparison with a solution of the same strength in benzene as shown in Curve II. It is apparent that the acetic acid solution ceased to react as soon as the light was turned off but the reaction in the benzene solution proceeded slowly for some time after the light was extinguished. Concordant velocity constants were calculated for both the acetic acid and the benzene solutions. The velocity constant as calculated by the monomolecular equation was 0.0023 for the benzene solution and 0.00065 for the acetic acid solution.

Some experiments were carried out to determine the effect of concentration of the solute in benzene as solvent and results similar to those found in acetic acid were obtained, as shown in Curves I and II, Fig. 2.

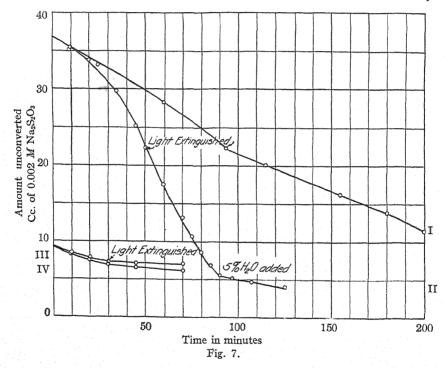

Curves I and II, Fig. 6, show the effect of temperature on the velocity of transformation of a 0.01 M solution in 95% alcohol. The temperature of the solution in Curve I was 0.7° and that in Curve II was 21.1°.

Curves III and IV show the effect of temperature on an absolute alcohol solution of $0.01\,M$ concentration. The temperature of the solution for Curve III was $0.3\,^{\circ}$ and for Curve IV was $21.2\,^{\circ}$. It will be noticed that the effect of temperature on the 95% alcohol solution is very much less marked than on the absolute alcohol solution. This is in accord with the usual low temperature coefficients of photochemical reactions. Dilute solutions of acetyl-chloro-aminobenzene in alcohol containing small amounts of water act like true photochemical reactions, as is shown in Fig. 7, Curve III, whereas in absolute alcohol solutions the reactions are

not true photochemical reactions, since the reaction proceeds without the light after the reaction is initiated, as is shown by Curves II and IV, Fig. 7. Therefore, the temperature coefficient of the reaction in absolute alcohol is equal to the coefficient for an ordinary chemical reaction.

In Fig. 7, the presence of small amounts of water is shown to have the effect of a negative catalyst. Curve II shows the velocity of transformation of a $0.04\,M$ solution in absolute alcohol with and without the light. No diminution whatever is noted when the light is extinguished after the reaction is initiated, but the addition of a small amount of water toward the end of the reaction causes a marked decrease in the velocity

of transformation. Curves III and IV show the effect of extinguishing the light when the solvent is 95% and partially dehydrated alcohol, respectively, and the concentration of the solute is only 0.01~M. Curves I and II show the results obtained with a stronger solution (0.04~M) in 95% and with partially dehydrated alcohol, respectively. The alcohol used in the solution for Curves II and IV was treated with anhydrous copper sulfate until only traces of water remained in the alcohol, but of course was not completely anhydrous. From these curves, it is seen that water retards the velocity of transformation, but its effect is reduced as the strength of the acetyl-chloro-aminobenzene is increased. For

example, the reaction stops completely in a $0.01\,M$ solution in 95% alcohol when the light is removed, as shown by Curve III, but is only slightly retarded when the concentration is increased to $0.04\,M$, as shown by Curve I.

Discussion of Results

Acetic Acid Solutions.—Others have shown that the transformation of acetyl-chloro-aminobenzene in dil. acetic acid solution is very slow in the absence of light. When hydrochloric or hydrobromic acid is added to the solution, however, the decomposition proceeds in the dark. With hydrochloric acid, the reaction is monomolecular, at least within certain limits of concentration, whereas with hydrobromic acid it is bimolecular. Our experiments show that a 0.01 M solution in 10% acetic acid containing 1% of 0.25 N hydrochloric acid showed no appreciable decomposition at the end of 3 hours. On the other hand, a solution containing 1% of hydrobromic acid in a 10% acetic acid solution of the same strength of acetyl-chloro-aminobenzene showed a marked decomposition. A higher concentration of hydrochloric acid, for example a solution containing 25% of N hydrochloric acid, produced rapid transformation in the dark. It appears from these experiments, therefore, that a certain concentration of hydrochloric acid is necessary before the transformation takes place.

The light reaction in 10 or 20% acetic acid appears to follow the equation for a monomolecular reaction, which is characteristic of photochemical reactions, but the velocity constant is not independent of the initial concentration of the solute, as is the case with monomolecular reactions. The velocity of the light reaction is the same whether the solution contains 10 or 20% acetic acid.

The sum of the velocities of the dark reaction with hydrobromic acid as catalyst plus the light reaction in 10% acetic acid is the same as for the light reaction in the case of a 10% acetic acid solution containing the same concentration of hydrobromic acid. The light reaction in the case of a 10% acetic acid solution containing hydrochloric acid as catalyst was somewhat greater than the sum of the light reaction in 10% acetic acid and the dark reaction with hydrochloric acid as catalyst.

In dilute acetic acid (10 or 20%) the transformation proceeds only under the influence of light but in a glacial acetic acid solution the reaction proceeds without the action of light after the reaction is started by the light.

Alcoholic Solutions.—Alcoholic solutions of acetyl-chloro-aminobenzene were found to behave similarly to those in acetic acid. $0.01\ M$ solutions in alcoholic solvent containing as much as 95% of alcohol appeared to give true photochemical reactions in that they proceeded only under the influence of light, showed a temperature coefficient of 1.23 and conformed to the equation for monomolecular reactions. The velocity constant was not independent of the concentration, however, but was only about half

as great when the concentration of solute was doubled, as was also the case in dil. acetic acid.

When the concentration of solute in 95% alcohol was increased to 0.04 M, however, the reaction ceased to be truly photochemical but continued after the light was extinguished, although at a diminished velocity.

In absolute alcohol the compound was stable in the dark but after the transformation was initiated by the light the reaction proceeded with undiminished velocity when the light was extinguished. The velocity was very much greater in the absence of water in both alcoholic and acetic acid solutions.

The temperature coefficient for the reaction in absolute alcohol was about 1.6 as compared with 1.23 for the reaction in dil. alcohol, which is characteristic of the difference between photochemical reactions and ordinary chemical reactions.

Benzene Solutions.—These experiments show that the velocity of transformation of acetyl-chloro-aminobenzene, when dissolved in benzene, under the influence of the light from a quartz mercury-vapor lamp, as well as the decomposition under the action of the light, is between that for dil. acetic acid and absolute alcohol solution. The velocity of the light reaction in benzene solution is about the same as in 95% alcohol. The velocity constants can be calculated for all concentrations tried by means of the equation for monomolecular reactions. The velocity constant is not independent of the concentration of the solute, however.

When the transformation is started in benzene solution by the action of light and the lamp is then extinguished, the reaction does not stop immediately as it does in 10% acetic acid solution of the same concentration nor does it continue without diminution as it does in an absolute alcohol solution, but the velocity decreases very rapidly for a short time and then very slowly.

Summary

The decomposition of acetyl-chloro-aminobenzene under the influence of the light from a quartz mercury-vapor lamp has been studied in various solvents. The solvent has been found to have a marked effect on the behavior of the reaction.

When water is added to an alcoholic or glacial acetic acid solution of acetyl-chloro-aminobenzene the velocity of the light reaction is greatly diminished. It also causes the reaction to proceed as a true photochemical reaction, whereas in the absence of water the reactions in absolute alcohol and glacial acetic acid solutions proceed without the action of light after the reaction is once initiated.

CHEMICAL ACTION PRODUCED BY RADON¹ III. THE DETERMINATION BY A CHEMICAL METHOD OF THE MEAN EFFECTIVE PATH OF ALPHA PARTICLES IN SMALL SPHERES²

By S. C. LIND AND D. C. BARDWELL RECEIVED JULY 27, 1923

1. In studying the relation between ionization and chemical reaction in gases containing radon, the ionization cannot be measured, but must be calculated from the quantity of radon and the mean path of the α particles in the gas being acted upon.³ The desirability of an exact knowledge of the mean path of the α particles is therefore apparent. The problem is simplified by using spherical reaction vessels. The mean path of all α particles projected (by radon) from all points within the sphere in all directions in straight lines until they strike the wall is $0.75 \times r$ (where r is the radius of a sphere). The mean path from all points on the inner surface (RaA and C) in all directions until the wall is again reached is $0.5 \times r$. But doubt exists as to the actual proportions of RaA and RaC that are on the wall when emitting α particles, which evidently would affect the length of path of the α particles emitted and hence the quantity of ionization. It appears impossible to settle this point with existing data on the rate of diffusion of active deposit; and while the direct determination can be made for RaC by means of its γ radiation, it is not possible for RaA. Saturation current methods of determining the ionization are also not applicable since the imposition of an electrical field would influence the deposition of active deposit.

The following indirect chemical method therefore appears to have promise, since it had already been shown by one of us³ that the rate of chemical combination of hydrogen and oxygen under the influence of radon mixed with them in spheres of different sizes is directly proportional to the radius of the sphere, and hence to the mean linear path of the α particles.

The proposed method based on the mean path principle is, in brief, to make a series of manometric measurements of the velocity of combination of electrolytic hydrogen and oxygen in the same sphere under two different

¹ The term *radon* is adopted for radium emanation, according to the recommendation of the International Committee on Chemical Elements. This Journal, **45**, 868 (1923).

³ Lind (a) This Journal, 41, 547 (1919); (b) American Chemical Society Monograph No. 2, "Chemical Effects of Alpha Particles and Electrons," Chemical Catalog Co., N. Y., 1921, p. 105.

conditions: (A) with the radon confined at the center of the reaction vessel in a minute α -ray bulb, which may be regarded provisionally as a point source of α radiation in all directions; (B) with the radon mixed in the reaction sphere with the hydrogen and oxygen. The sphere must, of course, be small enough for the α particles of shortest range to pass entirely across it in the given gases at the highest pressure employed.

In simplest terms, the velocity of chemical reaction in B will be proportional to the effective mean path of the α particles in the sphere, which

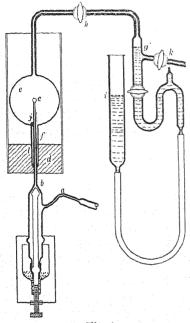

Fig. 1

is sought; while the velocity in A will be proportional to a path which must be the radius r itself. Therefore, the ratio chem. velocity (B) chem. velocity (A) represents a fraction of the radius which is the mean path sought in B. A number of corrections are to be applied which are considered later.

2. The Experimental Method.—The apparatus used for Method A is shown in Figs. 1 and 2. Radon was collected from a solution containing 220 mg. of radium element as 50% radium barium chloride, Ra(Ba)Cl. dissolved in 5% hydrochloric acid. The method used to obtain radon purer than is needed for therapeutic purposes has been previously described.⁴ The radon and residual gases must, after purification, occupy a volume not exceeding 1 to 2 cu. mm. at a pressure of 1 to 2 atmospheres. The elec-

trolytic mixture of hydrogen and oxygen (dry) is first introduced through the stopcocks k and h to give the desired pressure in e. The purified radon is then passed from the purification train (not shown) through the capillary tube a past a ground glass valve b. Finally b is closed so as to confine the radon in front of the mercury just at the neck of the α -ray bulb e. The ground glass valve e is adopted from Taylor, e

⁴ (a) Lind, Am. Chem. J., 47, 406 (1912); (b) Sitzb. Wien Akad., 120, IIa, 1714, (1911).

⁵ To minimize the danger of puncturing c (Fig. 2) by sparking through, as a result of the accumulation of unipolar charge, a very fine platinum wire (l) was sealed through the capillary wall between d and f making contact with the mercury in the capillary and continuing at the other end well up into e. A blank test showed that this small quantity of platinum does not catalyze measurably the combination of hydrogen and oxygen.

⁶ Taylor, This Journal, 37, 30 (1915).

but without his silica rod temperature compensator. By making the bore of the capillary between b and c and hence the volume of mercury very small, it was found that temperature compensation could be dispensed with over a range of 10° , which was two or three times the actual maximum fluctuation.

Owing to the difficulty of blowing an α -ray bulb on a very short capillary, it was found necessary to make the glass in-seal d at a greater distance from c than could be allowed for the radius of the reaction sphere e. Consequently a dead arm (for radiation but open to hydrogen and oxygen) occurs in the annular space along f. Attempts to fill in f with inert material failed; mercury has the disadvantage of contributing vapor to e so that a deposit of oxide formed on c, owing to the oxidizing conditions in the intense ionization region around it, resulting in a prohibitive increase of stopping power of e for e rays. Attempts to fill in e with fused salt also failed, because the salt (cutectic mixture of lead chloride and silver chloride) upon solidifying broke the thin capillary. The dead arm had, therefore, to be filled with the electrolytic gas, which introduces a correction that will be treated subsequently.

In the reaction sphere e small areas of a mixture of potassium and sodium oxides were fused flat upon the wall in two or three places for desiccation. The manometric measurements of the course of the reaction were made by reading at g, separated from e by a 0.5mm. capillary 10 cm. long and by a stopcock h to prevent diffusion of mercury vapor into e. Except at the time of readings the mercury level is raised into the capillary. The mercury levels at g and in the leveling bulb at i were read with a cathetometer without

Fig. 2

detaching from the apparatus so as to avoid disturbing the mercury setting at c which is very delicate.

The procedure B is identical with A just described except that in B the radon is allowed to mix with the hydrogen + oxygen in e by breaking c. This is accomplished (after Procedure A has been followed for 2 or 3 days so as to obtain a good set of velocity constants) by lifting the "magnetic capsule" j with an electro-magnet and allowing it to fall against c which is readily crushed owing to its extreme thinness (about 0.0025 mm.). This "magnetic capsule" is merely a soft iron pin (3 mm. long and 2 mm. in diameter) enclosed in a glass shell of total volume 0.2 cc. In method B the dead arm f is then filled with mercury (from the manometer) exactly up to the shoulder, thus making the reaction vessel e a perfect sphere.

The general procedure just described not only furnishes a convenient method of continuing B from A with the same radon and the same elec-

 $^{^{7}}$ Use of a liquid-air trap to stop mercury vapor during the short reading intervals when h is open was found unnecessary.

trolytic gas, but also possesses the great advantage of making the comparison of the two velocities independent of any γ -ray measurement of the quantity of radon (which is the same in both cases, taking into account, of course, the decay factor).⁸

The pumps used for evacuation were a mercury vapor diffusion pump of Pyrex glass backed up by a Gaede rotary oil pump. A vacuum of 10^{-5} mm. (neglecting mercury vapor) was attained in the system before the purification and introduction of radon was begun.

The manometric measurements were never begun until radon had been in place for 4 hours to insure equilibrium with and definite position of RaA and RaC. The initial pressure P_0 , and E_0 the initial quantity of radon refer, of course, to the same zero time t_0 .

3. Experimental Results and Calculations.—For the sake of confirmation, two independent experiments were made using reaction spheres of different diameters and α -ray bulbs of slightly different dimensions. In Table I the dimensions of both are given. The factors primarily controlling the velocity are the quantity of radon present, the pressure of the reacting gases, and the dimensions of the reaction vessels. The other

 $T_{ABLE} \; I$ Dimensions of Reaction Spheres and of $\alpha\textsc{-Ray}$ Bulbs for Expts. 1 and 2

	Reaction sphere			cr-Ray bulb9			
	Diameter Cm.	Volume Cc.	Vol. of dead arm Cc.	bulb Cm.	-Diameter o neck Cm.	tip Cm.	Wall thickness Cm.
Expt. 1	3.563	23.69	1.16	0.159	0.063	0.042	0.00025
Expt. 2	4.259	40.46	1.07	.145	.047	.046	.00025

 $^{^8}$ γ -Ray measurements of the radon were made in order to give an absolute value to the velocity constants reported, but they are not regarded as very accurate because in passing radon over the ground-glass valve b some of it invariably was trapped by the rough surfaces. This rendered heavy screening of b necessary during the subsequent γ -ray measurement, thus introducing uncertainties not arising in the ordinary γ -ray measurement of Rn.

⁹ The measurements of the bulb, neck and tip were made by means of a calibrated micrometer eye-piece (1 div. = 0.00234 cm.); those of the wall thickness by viewing the edge of the broken wall (1 div. = 0.000124 cm.). A preliminary measurement of the wall thickness to determine before use, the suitability of each bulb, was made radiometrically by means of a zinc sulfide screen after introducing radon.¹0 The value obtained for wall thickness by the radiometric method was about twice as great as that by the microscopic method. The discrepancy is probably ascribable to the failure of the screen to render α-rays visible at the extreme ends of their paths. Although the discrepancy involved in the two methods of measurement is but 1 to 6 mms. of the total path in air, the employment of a difference method magnifies the error to one of 2-fold. Hence, for accurate purposes the microscopic method is preferable. It has the disadvantage that it can only be applied after destruction of the bulb, so that the radiometric method will still be essential for preliminary examination in selecting suitable bulbs. The factor for converting glass into air equivalent, used later in the corrections, is 1 cm. air at 20° and 760 mm. ≈ 0.0056 mm. of glass.

¹⁰ Ref. 4a, p. 397. Ref. 3b, p. 76.

dimensions given in Table I are of secondary importance in later calculating the various corrections involved.

In Table II will be found the experimental results in detail for Expt. 1, and immediately following them a summary of results from Expt. 2, obtained in the same way. The calculations of the velocity constants from the observed changes of pressure involve only the two equations previously given.¹¹

$$\frac{k\mu}{\lambda} = \frac{\log \frac{P_0}{P}}{E_0 (1 - e^{-\lambda t})} \tag{1}$$

and
$$\left(\frac{k\mu}{\lambda}\right)' = \frac{\log \frac{P_1}{P_2}}{E_0 \left(e^{-\lambda l_1} - e^{-\lambda l_2}\right)}$$
 (2)

Equation 1 is the form for calculation from the initial pressure P_0 to any pressure P_t through the entire interval of time. Equation 2 is the form for the usual "point to point" method of calculation to show absence of trend in the constant. $\frac{k\mu}{\lambda}$ and $\left(\frac{k\mu}{\lambda}\right)'$ may be regarded, for present purposes, merely as velocity constants, without regard to the significance of the separate symbols.

For Expt. 2, carried out in the same way between pressure limits of hydrogen plus oxygen (A) 579.7 to 458.1 mm. in 2 days and 0.5 hour, and (B) 453.5 to 358.4 mm. in 7 days and 11.5 hours, the velocity consts. obtained ¹¹ Ref. 3a, pp. 536, 543. Ref. 3b, pp. 96, 108,

were: A,
$$\frac{k \mu}{\lambda} = 7.05$$
; $\left(\frac{k \mu}{\lambda}\right)' = 7.05$, with $E_1 = 0.1094$ curie. B, $\frac{k \mu}{\lambda} = 4.64$; $\left(\frac{k \mu}{\lambda}\right)' = 4.63$, with $E_0 = 0.0690$ curie.

4. Discussion of Results.—This is the first instance in which the manometric course of a gas reaction produced by radon in an α -ray bulb has been determined. While the manipulation involved is far more difficult than that for mixtures (Method B), it is nevertheless essential to use α -ray bulbs in some cases. It is, therefore, gratifying to know that with suitable manipulation they can be used as a source of α radiation which obeys satisfactorily the theoretical previsions.

A direct comparison of the two velocities, Methods A and B for Expts. 1 and 2, as just reported, shows that radon is more effective when radiating from the center than in the mixture in the proportions: $\frac{9.46}{6.65} = 1.42$ and

 $\frac{7.05}{4.63} = 1.52$, which are direct experimental efficiency factors. According to the statements of Section 1, their reciprocals, 0.704 and 0.657, would represent values 12 for the fraction f of the radius being sought, if the average path equal $f \times r$. Evidently the values cannot be accepted without a number of corrections, which largely remove their disagreement.

In order to avoid complication, a full treatment of all the corrections involved in both methods (A) and (B) is presented in a separate paper. It suffices here to enumerate them. The corrections which apply to the α -ray bulb are (1) for tip and neck, (2) correction to zero diameter, (3) for wall thickness and oblique passage of α particles through it. Those applying to the reaction sphere are (4) dead arm for Method A, (5) average intensity of ionization as dependent on the pressure of the reacting gases, (6) recoil atom effect (absent in Method A). By applying these corrections, as shown in detail in the subsequent paper, a final value for that fraction of the radius which is equivalent to the mean path is obtained. That from Expt. 1 is $0.615\ r$ and from Expt. 2 is $0.609\ r$, which values, within the limits of error may be regarded as identical, $(0.61 \pm 0.01)\ r$. This value has been corrected to the following conditions of ionization: sphere of 2 cm. diameter containing air at 320 mm. and 0°. Theoretically, the value $0.61\ r$ holds accurately only for these conditions, and the drift or

¹² Similar results were obtained in two single experiments by Scheuer [Compt. rend., 159, 423 (1914)] but were not of such a character that they could be used to obtain an accurate value of f. Scheuer stated the differences in velocity in terms of M/N values. This is, of course, an error, arising from his employment of the Duane and Laborde formula for calculating ionization in both cases which is not at all permissible for the α -ray bulb. Evidently, it is the length of path and the resultant ionization which is increased by use of the α -ray bulb; the M/N ratios remain constant.

¹³ Bardwell and Doerner, This Journal, 45, 2593 (1923).

diffusion of active deposit to the wall should depend on the length of path times the density of the gas traversed. That one is not dealing with normal diffusion is evident from the results of Debierne.14. So far as these and previous experimental results show, the proportion of active deposit on the wall is constant through quite a range of pressures and diameters. For example, if drift or diffusion has a determining influence, one would expect in Expt. 2 (when both the diameter and pressure were larger than in Expt. 1) to obtain a larger value of f, yet one slightly smaller was obtained. As far as is known at present the fraction of active deposit on the walls may be maintained practically constant by some other influence than diffusion. We assume, therefore, that the mean linear path traversed by α particles in the sphere is constant over a fairly wide range of pressure. The ionization itself, however, will change with pressure along a given path according to the Geiger ionization curve. We give in Table III. therefore, some interpolated values of average intensity of ionization. These data may be used for any other gas or mixture of gases by reducing to the basis of air by means of the specific ionization.

TABLE IIIa

Average Intensity of Ionization for Radon Mixed with Air in a Bulb of 2 Cm. Diameter at 0°

Pressure in mm. of Hg	100	300	500	700	900
Ion pairs × 104 per cm					

^a The number of ions per centimeter of path is based on the value 2.37×10^5 for the total path in air for Radium C. H. Fonovits-Smereker has recently reported [Sitzb. Akad. Wiss. Wien. II_a, 131, 355-63 (1923)] a value 2.20×10^5 . The values in Table 3 may be converted by multiplying by the factor 2.20/2.37, if desired.

It remains to discuss the probability of the result obtained. By referring to Table IV, it will be seen that the value 0.61 r lies well within

		r	ABLE IV

the theoretical limits (0.58 to 0.75 r), which is a further independent confirmation of the average-path theory of α -ray chemical action. An in¹⁴ Debierne, "Le Radium," 6, 97 (1909).

terpretation of the result is possible from the standpoint of distribution. For 90.8% RaC¹⁵ on the wall at the time of α -ray emission, the value 0.61 r will be satisfied by 77.2% of RaA on the wall. This distribution is intermediate between that to be expected if deposition were controlled solely by the rate of reaching the wall (taking into account the decay rates of RaA, and RaC through RaB) and that previously assumed by Lind³ of 100% deposition of both RaA and RaC. The value 0.61 r will be used in all future calculations for gas mixtures in small spheres, unless otherwise stated, and will later be used for correcting some previous calculations.

The last line of Table IV will not be clearly understood without reference to the following paper but, in brief, means that a full consideration of the complete or partial suppression of α particles owing to their oblique passage at different angles through the wall of the α -ray bulb, with regard merely to their subsequent *linear* paths through the gas phase and without reference to ionization at all, leads to a value 0.53 r for the average linear path in mixtures, which is less than 0.58 r, the lowest theoretically possible. Hence, the mere *linear relations* without resort to *ionization*, are incapable of explaining the quantity of chemical combination observed. This is further evidence in support of the ionic-chemical hypothesis.

It is a pleasure to acknowledge the valuable assistance of Professor J. C. Jones of the University of Nevada in making the microscopic measurements of the wall thickness of the α -ray bulbs.

Summary

- 1. By means of a chemical comparison method consisting of the measurement of the velocities of combination of electrolytic hydrogen and oxygen under the influence of radon in equilibrium with RaC, (A) when confined in an α -ray bulb at the center of the reaction sphere, (B) when mixed with the gases, it was found that the mean effective path of the α particle (in mixtures) is $0.61 \pm 0.01 \times$ the radius.
- 2. The direct micrometer measurement of the walls of α -ray bulbs showed them to be about half as thick as indicated by the zinc sulfide screen radiometric method.

CHEMICAL ACTION PRODUCED BY RADON IV. CHARACTERISTICS OF THE ALPHA-RAY BULB AS A SOURCE OF IONIZATION¹

By D. C. BARDWELL AND H. A. DOERNER

RECEIVED JULY 27, 1923

The corrections necessary to reduce the experimental efficiency factors reported in the preceding paper to the exact value, $(0.61 \pm 0.01) \ r$, (the mean effective path of α particles in a sphere of radius r) will be considered.

The construction of α -ray bulbs was first developed by Lind and Duane and has been described in detail by Lind.² Although very thin bulbs are desirable, there is a practical limit of thinness, dependent on the diameter of the bulb. Moreover, the α -ray bulb is not a perfect spherical shell; it has a fin. t. (Fig. 1) of relatively thick glass and a capillary con-

it has a tip, t, (Fig. 1) of relatively thick glass and a capillary connection m. Alpha particles striking either the tip or mercury in the neck (at the shoulder of the bulb) are lost. This loss should be made as small as possible, but reduction of the diameter of the neck below 0.4 mm. is not practical, for it would be difficult to maintain a perfect setting of the mercury. The column of mercury in a very small neck has a tendency to separate, throwing a droplet of mercury into the bulb, which it is impossible to

Fig. 1

reunite. The complete corrections necessary to establish the α radiation from such bulbs require rather laborious calculations for each set of dimensions. From the manipulative standpoint, bulbs 1.5 mm. in diameter with wall thickness of 0.0025 mm. are most satisfactory. Hence, we have used bulbs as nearly as possible of this size. Our calculations regarding ionization will be rigidly correct only for such α -ray bulbs.

1. Correction for Tip and Neck.—In a bulb of 1.5 mm. diameter, containing radon, we have assumed that RaA and RaC (in equilibrium) are deposited uniformly upon the wall, and that from any point in the bulb or upon the wall, the emission of α particles is uniform in every direction. Let a and b be the solid angles subtended from the center of the bulb by the tip and neck, respectively. The fraction of the total surface represented by the tip and neck is $(a + b)/4\pi$. The fraction of the surface which is effective in radiating is $1 - [(a + b)/4\pi]$. If $k\mu/\lambda$ is the ve-

locity constant for an actual α -ray bulb, the velocity constant for a theoretically perfect bulb (without tip or neck) is $\frac{k\mu}{\lambda} \cdot \frac{1}{1-\frac{a+b}{4\pi}}$.

- 2. Correction for the Radius of the α -Ray Bulb.—Let r be the radius of the reaction sphere and R be the radius of the α -ray bulb. The distance traversed by an α particle emerging normally from the α -ray bulb is r-R. For the theoretical case of an α -ray bulb of zero radius, the distance traversed would be r. The velocity constant for a theoretical α -ray bulb (with no tip or neck and zero radius) is $\frac{k\mu}{\lambda} \cdot \frac{1}{1-\frac{a+b}{4\pi}} \cdot \frac{\gamma}{r-R}$.
- 3. Calculation of the Effective Average Intensity of Ionization.—In calculating the ionization produced by any given α particle emerging from the bulb and traversing the gas phase, two factors must be considered: (1) the obliquity of passage through the wall; (2) the change of ionization along the path as expressed by the Geiger curve. Evidently (2) is dependent upon (1). The ionization (Fig. 2) from (o) to (l) is represented approximately by an expression of the type, $y = \frac{K}{(R-x)^{1/2}}$ where y is the intensity of ionization at any point x, and R is the range from (o) to (1). The constant K is dependent upon the gas traversed and its pressure. The end of the curve (1) to (m) is nearly a straight line and must be represented by a separate equation. Bragg⁶ showed that the shape of the ionization curve is only approximately the same for all gases when the abscissas are adjusted to represent the same stopping power. Thus, Henderson's curve⁷ for air is not exactly similar to the one found by Geiger for hydrogen. For the electrolytic mixture of hydrogen and oxygen used, we therefore construct a composite curve (Fig. 2) from the separate curves for hydrogen (Geiger) and air (Henderson), giving the hydrogen values double weight. The abscissas are retained as those of air at 20° and 760 mm. pressure. The ranges of α particles from Rn, RaA and RaC are taken as 4.23, 4.83 and 7.06 cm., respectively. For the pressure changes in Expts. 1 and 2 of the preceding paper the path of an α particle from the inner to the outer bulb is equivalent to an abscissa difference varying between 0.40 and 0.75 cm. A preliminary set of calculations of the ionization showed that the average intensity of ionization from an α -ray bulb

³ The correction for oblique rays is taken up in Section 3.

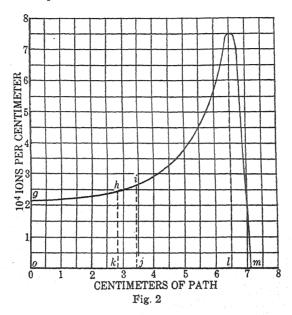

⁴ The effect of obliquity was treated graphically by Lind in ozone formation (Ref. 2). In those experiments, the reaction chamber was so large that no α particles reached the outer wall, so that Correction 2 did not arise.

⁵ Geiger, Proc. Roy. Soc., 83A, 505 (1910).

⁶ W. H. Bragg, "Studies in Radioactivity," 1912, Chapters 5 and 6.

⁷ Henderson, Phil. Mag., 42, 538 (1921).

is constant through this range of path. We therefore calculate the effective average intensity of ionization of α particles emerging from an α -ray bulb as used in these experiments as follows.

Consider a point b on the inner surface of the α -ray bulb shell abc (Fig. 3). θ is the angle between the oblique pencil of rays bc and the

normal pencil bd. For increasing values of θ , the path through the glass wall increases until at 87° no α particles, even from RaC, emerge from the bulbs used. For angles of θ greater than 90°, the pencil passes through the interior of the α -ray bulb before it reaches the wall. However, the wall thickness traversed by such pencils is the same as for the supplementary angle, due to the symmetry of a secant intercepting the walls

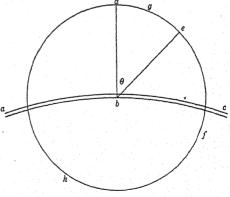

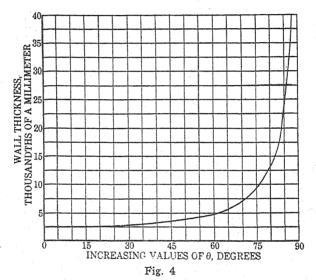

Fig. 3

of a spherical shell. It is therefore necessary to consider only the average effect of α particles emerging at angles less than 90°. The thickness of glass traversed for increasing values of θ was calculated geometrically from the diameter and wall thickness. A plot was made of the thickness

as a function of Θ (Fig. 4). The lengths of path (in terms of air) cut off by the shell were listed for the following angles: 0° ; 7.5; 15; 22.5; 30.0, 37.5, 45; 52.5; 60; 67.5; 71.25; 75; 76.8; 78.8; 80.63; 82.5; 84.38; 86.25; 87.2, 88.13, 90.0. They are represented (Fig. 2) by the variable ok. The path in the reaction vessel for each pencil is represented by kj; and the number of ions by the area hijk. The area divided by kj gives an average ordinate for each pencil which we shall call intensity of ionization.

The next step is to determine the relative number of α particles emerging in each pencil. For convenience, circumscribe a sphere of radius bd about the point b (Fig. 3). A circular section dgefh is cut out by a plane through the normal to the surface of the α -ray shell at b. Assume

that the intensity of ionization for a pencil with angle θ_n is the average for the bundle bounded by $\theta_n - \frac{1}{2}(\theta_n - \theta_{n-1})$ on one side and by $\theta_n + \frac{1}{2}(\theta_{n+1} - \theta_n)$ on the other, where θ_n is the *n*th angle. The bundle thus bounded we designate as $\Delta\theta_n$. Further reduction (see list given above) of the size of $\Delta\theta_n$ does not appreciably increase the accuracy of the summation that follows. If $\Delta\theta_n$ is revolved about the normal bd, it cuts out a zone of revolution from the circumscribing sphere. The area of this zone divided by half the area of the circumscribing sphere represents the fraction of α particles emerging in the bundle $\Delta\theta_n$.

An additional variable must be considered. In Section 2 a correction for the radius of the α -ray bulb was discussed. The distance traversed by an α particle from the inner to the outer bulb is also a variable and a function of Θ . As Θ increases, this distance increases. To correct for this increase in distance, the fraction of α particles in the bundle $\Delta\Theta_n$ is

weighted by multiplying by the ratio of the distance at the angle θ_n to the normal distance.

A summation of the products of the intensity of ionization for each bundle by the effective fraction of α particles emerging in the bundle, gives the effective average intensity of ionization of all the α particles emitted by one of the radioactive elements. These calculations were made for RaA and RaC (assumed to be on the wall of the α -ray bulb) and for Rn (gaseous distribution). For radon (gaseous distribution) the α -ray bulb was divided into eight spherical shells. The average intensity of ionization was calculated for the mean radius of each shell and multiplied by the percentage of the volume included. Since the average intensity of ionization increases more rapidly for points near the surface, outer shells were chosen to contain smaller volumes. The average for the three sets will be designated as I_A . For Expt. 1A (preceding article), $I_A = 2.659 \times 10^4 \frac{\rm ions}{\rm cm}$ (referred to

air at 20°, 760 mm.) and for Expt. 2A, $I_A = 2.645 \times 10^4 \frac{\text{ions}}{\text{cm}}$

4. Correction for Dead Arm.—As explained in the preceding paper, a dead arm containing gas which is not radiated was necessitated in mounting α -ray bulbs for Expts. 1 and 2. The quantitative effect of the dead arm upon the velocity constant is easily deduced by examining the differential equation for the rate of change in pressure. Let $-\frac{dP}{dt} = k \mu E_0 e^{-\lambda t} P$ for the case where there is no dead arm. If a dead arm is attached the effectiveness of the α particle is not altered, and hence the same number of molecules react per unit time. But the total volume of gas has been increased by the volume of the dead arm; therefore the rate of change in pressure with dead arm will be equal to $\frac{\text{vol. of bulb proper}}{\text{vol. of bulb proper} + \text{dead arm}}$ rate of change of pressure without dead arm. These relations are not altered in the integrated form of the velocity equation. The velocity constant in Expts. 1A and 2A would be, if there were no dead arm, equal to: $\frac{k\mu}{\lambda}$ (Expt.1) $\times \frac{\text{vol. of bulb proper} + \text{dead arm}}{\text{vol. of bulb proper}}$. The numerical substitution of values for these corrections in Expts. 1 and 2 will be deferred until the corrections for mixtures are discussed.

- 5. Average Intensity of Ionization when Radon is Mixed with the Gases.—A method similar to that employed in Section 3 was used to calculate the average intensity of ionization in mixtures. The method of obtaining average ordinates was different in that, for the case of mixtures,
- 8 A few oblique α particles are probably directed into the dead arm, but they are at least compensated by those oblique α particles which are lost in the projections of the tip and neck of the α -ray bulb outside the bulb.

no part of the path of an α particle is cut off by glass before it traverses the gas phase. The method of weighting was identical with that in Section 3. Values of θ from 0° to 180° in intervals of 7.5° , were used. Calculations were made, first, for RaA and RaC assumed to be on the wall of the reaction sphere; second, for gaseous distribution of Rn, RaA and RaC. To obtain the values for gaseous distribution, the average intensity of ionization was calculated for five points along the radius of the reaction sphere so placed as to be the average radius for approximately equal volumes of gas. For radon the average intensity of ionization for points on the wall and at the center were, respectively, 2.518×10^4 and 2.576×10^4 ions per cm. The values for the other points lay at approximately equal intervals between these two values. We therefore took the mean of the two extremes. For Radium A, the average intensity of ionization is less than 1% higher for gaseous distribution than for the wall, and for RaC it is the same in both cases. It is therefore unnecessary to make any assumption in regard to the distribution of RaA and RaC. The average intensity of ionization for the three sets of α particles, in mixtures we designate as I_B . For Expt. 1B (at 350 mm.), $I_B = 2.375 \times 10^4 \frac{\text{ions}}{\text{cm}}$ (referred to air at 20° and 760 mm.); and for Expt. 2B (at 450 mm.), $I_B = 2.398 \times 10^4 \frac{\text{ions}}{\text{cm}}$.

6. Recoil Atom Effect.—Lind⁹ has shown that recoil atoms from Rn, RaA and RaC produce chemical action to an extent which cannot be neglected in Expts. 1B and 2B. 10

The combined chemical effect of α rays and recoil atoms is double the α -ray effect at 116.8 mm. of electrolytic hydrogen and oxygen in a sphere of 1 cm. diameter. Assuming that the relations are similar in large bulbs (for example that in one of 2 cm. diameter the rate is doubled at a pressure of 116.8/2 mm., etc.) the relative effects can be calculated for the mixtures in Expts. 1 and 2. Evidently recoil atoms are absent when α -ray bulbs are used, which also has recently been experimentally proved. ¹⁰

In Expt. 1B at a pressure of 350 mm. the α -ray effect is 91.6% of the combined effects. In Expt. 2B, at a pressure of 450 mm. it is 94.4%.

7. Application of Corrections.—The velocity constants for Method A, referred to a perfect α -ray bulb of zero radius, no dead arm, and to the initial ordinates of the ionization curve for all three sets of α -particles are:

Expt. 1A,
$$9.46 \times 1.0626 \times 1.0466 \times \frac{2.330}{2.659} \times 1.0488 = 9.67$$
; Expt. 2A,

⁹ Lind, This Journal, 41, 533 (1919).

¹⁰ The reality of the recoil atom effect has been verified by new experiments which will be described subsequently. The new data are used for the corrections, but do not differ greatly from the previous results.

$$7.05 \times 1.0564 \times 1.0353 \times \frac{2.330}{2.645} \times 1.02647 = 6.97.$$

The velocity constants for pure α -ray effect corrected for volume of "magnetic capsule," and referred to initial ordinates on the ionization curve are: Expt. 1B, $6.65 \times 0.995 \times 0.916 \times \frac{2.33}{2.375} = 5.95$; Expt. 2B, $4.64 \times 0.996 \times 0.944 \times \frac{2.33}{2.398} = 4.24$.

The average path in Method A is the radius of the reaction sphere. Therefore, the average path in Method B is for Expt. 1 equal to $\frac{5.95}{9.67} \times r =$

0.615 r, and for Expt. 2 equal to $\frac{4.24}{6.97} \times r = 0.600$ r. These values are reported and discussed in the preceding paper.

It was found from the data obtained by methods described in Section 3, that 94.4% of the α rays get through the α -ray bulb. Assuming that the velocity of reaction is proportional merely to the linear path of the α ray in the gas phase, the velocity constants for Method A (no ionization considerations) are: Expt. 1A, $9.46 \times 1.030 \times 1.0488 \times 1.0626 \times 1.059 = 11.50$; Expt. 2A, $7.05 \times 1.024 \times 1.02647 \times 1.0564 \times 1.059 = 8.28$. The velocity constants for Method B are: Expt. 1B, $6.65 \times 0.995 \times 0.916 = 6.06$; Expt. 2B, $4.64 \times 0.996 \times 0.944 = 4.36$.

The average path in mixtures would be for Expt.1 equal to $\frac{6.06}{11.50}r = 0.527r$, and for Expt. 2 equal to $\frac{4.36}{8.28}r = 0.527r$, or to the limits of accuracy, 0.53 r. This value has no reasonable interpretation and is discussed in the preceding paper.

Summary

For the corrections involved in Part III, a knowledge of the characteristics of the α -ray bulb as a radiator, as affected by the tip and neck, by the thickness of the wall and obliquity of passage of α particles through it, and by the diameter of the bulb (reducing it to zero dimensions in order to afford radiation from a point source) is necessary. In addition, the other corrections applying to the outer sphere itself are treated, such as the deadarm correction and the change of ionization intensity with the pressure. The recoil atom effect is also used as a correction for the results, to reduce them to the same conditions as those obtaining outside the α -ray bulb, through which recoil atoms cannot penetrate.

THE INTERFERENCE OF COBALT IN THE BISMUTHATE METHOD FOR MANGANESE!

By G. E. F. LUNDELL²

RECEIVED AUGUST 9, 1923

The conditions recommended by Blum³ for the determination of manganese by the bismuthate method are as follows: "To the manganese solution containing 20 to 40% (by volume) of nitric acid (free from nitrous acid) in a volume of 50 to 150 cc., add a slight excess of bismuthate (usually 0.5 to 1.0 g.), agitate thoroughly for about one-half minute, wash down the sides of the flask with 3% nitric acid, filter through asbestos, wash with 100 cc. of 3% nitric acid, add a slight excess of ferrous sulfate, and titrate at once with permanganate."

To these may be added the following: (1) the solution should not contain more than 0.05 g. of manganese; (2) moderate amounts of sulfuric acid are not harmful, as for instance 5 cc. of sulfuric acid and 10 cc. of nitric acid in a 50 cc. solution; (3) chlorides must be absent; (4) the temperature of the solution may be varied from 5° to 25°; (5) one-half minute is enough for the reaction if the solution is agitated, but a longer period will do no harm; (6) new, and also stored, bismuthate should be tested for its oxidizing power; this is easily done by trying the bismuthate method on portions of permanganate solution which have been reduced and comparing the consumption of ferrous sulfate with that obtained by direct titration; (7) unless the asbestos has been very carefully freed from hydrochloric acid and chlorides, the first run through it will always be low; to make certain, it is well to pass through the filter a dil. nitric acid solution of permanganate containing a small amount of bismuthate and then to wash it with 3\% nitric acid before regular filtration; (8) the ferrous sulfate solution should not be allowed to stand for more than 10 minutes before the titration with permanganate, and its permanganate equivalent is best found by the titration of a suitable volume of ferrous sulfate which has been added to the filtrate obtained in a blank run on the bismuthate, acid, filtration, etc.; (9) the permanganate solution which may be either 0.03 or 0.1 N depending on the percentage of manganese involved is best standardized against sodium oxalate as described by McBride,4 and a properly prepared and filtered solution should preserve its strength for several

⁴ McBride, *ibid.*, **34**, 415 (1912).

months exposed to diffused light, if protected from dust and reducing substances. In the presence of the latter, solutions containing potassium hydroxide decompose less rapidly than do neutral solutions.³

For amounts of manganese up to 0.05 g. the accuracy of the above method can be safely regarded as within 1 part in 500. The procedure is singularly free from interference by other elements, and the only elements that have been recognized as troublesome are chromium and cerium. Some elements introduce minor difficulties as, for example, the color interference of concentrated solutions of copper or nickel salts, the delayed end-point caused by vanadium, the slightly low results caused by antimony, and the slightly high results caused by silver.

Vanadium causes trouble because it is at first oxidized to the quinquevalent state, then reduced to the quadrivalent condition, and finally reoxidized with some difficulty by the very small excess of permanganate which is permissible at the end-point. If it is not completely reoxidized, the results for manganese will of course be high.

Antimony is also oxidized to the quinquevalent state by sodium bismuthate, but only a very small part is reduced by ferrous sulfate in the cool solution which is employed. In further contrast to vanadium, antimony causes the results to be slightly low as, for example, 0.0109 instead of 0.0111 g. of manganese in the presence of 0.05 g. of antimony. Neither the cause of the error nor any remedy save prior removal of the antimony or the use of another method is known to me. If another method is used, Ford's⁵ is to be preferred for accurate analyses, and the persulfate-arsenite method for routine analyses.

Silver introduces slight difficulties as it causes the formation of oxides of nitrogen. The effect is not serious with ordinary amounts of silver as shown by the results 0.0112 and 0.0113 instead of 0.0111 g. of manganese in the presence of 0.01 and 0.1 g., respectively, of silver.

Chromium interferes because it is never completely oxidized at any stage. Only a part of it is oxidized by bismuthate and permanganic acid at the start; this is then reduced by ferrous sulfate, and finally a much smaller part is reoxidized during the final titration. Chromium therefore tends to cause results for manganese to be high. As either oxidation proceeds slowly in cool solutions, good results for manganese can be obtained in the routine analysis of steels containing moderate amounts of chromium and no vanadium by working rapidly (½ to 1 minute reaction) with solutions at a temperature not over 20°. Under such conditions, and especially if ice-cold solutions are used, vanadium causes some trouble as it is reoxidized with difficulty. Hence, such a method works quite well with chrome-nickel, but not so well with chrome-vanadium steels.

⁵ Blair, "The Chemical Analysis of Iron," 8th ed., J. B. Lippincott and Co., 1918, pp. 108-110.

Satisfactory results can be achieved with both steels by using suitable reducing solutions in place of ferrous sulfate, as for example sodium arsenite or mercurous nitrate, which reduce permanganate but not chromate or vanadate.

Cerium is rapidly oxidized to the quadrivalent state by bismuthate (even in cold solution) and subsequently reduced by ferrous sulfate to the trivalent state. Hence cerium will cause high results for manganese unless it is previously removed or a proper reducing agent, such as sodium arsenite, substituted for ferrous sulfate.

Cobalt, in contrast with all of the above, is a real interfering element in the bismuthate method and must be removed if bismuthate is to be used.⁷ This follows because it is oxidized by bismuthate at all temperatures that are permissible for manganese, and the oxidized compound reacts with both ferrous sulfate and permanganic acid. Cobalt upon oxidation approaches the formula Co₃O₄ and the color changes from pink to green.⁸ The oxidized compound reacts with ferrous sulfate, but not directly with permanganic acid. If, however, it is first treated with manganous nitrate and then with permanganate, a reaction does take place as evidenced by a change of color to an amber tint. This solution in the course of time shows a reappearance of the permanganate tint and yields a brown deposit of manganese dioxide together with some oxide of bismuth. The reaction between the oxidized cobalt compound and permanganic acid waits, therefore, upon some decomposition of the latter. When once started, it proceeds with considerable rapidity, and as the resultant compound does not react rapidly with ferrous sulfate, the net result is a lowered consumption of ferrous sulfate with consequent low values for manganese. The extent of the effect is indicated in Table I. In every case measured portions of a standard permanganate solution were reduced by sulfur dioxide, boiled to expel gas, cobalt was added as shown and then enough nitric acid to obtain 40 cc. of a 30% (by volume) solution. This solution was then cooled to 15-20°, treated with an excess of bismuthate, shaken occasionally during three minutes and then diluted with 50 cc. of 3% (by volume) nitric acid, filtered through asbestos and washed with the same acid. The solution was finally treated with a measured excess of ferrous sulfate and titrated with standard permanganate.

- ⁶ F. J. Metzger, This Journal, 31, 523 (1909).
- ⁷ So far as I know, no reference to its behavior in the bismuthate method has been made, save the note "This method (the bismuthate) cannot be used in the presence of cobalt" recommended by me and inserted in the Tentative Methods for the Analysis of Plain Carbon Steel, *Proc. Am. Soc. Testing Materials*, 22, Part I, p. 589 (1922).
- ⁸ A similar and striking change also takes place when a dil. sulfuric acid solution of cobalt sulfate is electrolyzed in a U-tube with moderately long limbs. The liquid in the cathode limb remains pink while that in the anode gradually turns green. Low current must be used, as the oxidized compound is unstable in a warm solution.

TABLE I

The Effect of Cobalt in the Bismuthate Method for Manganese Weight of manganese added, 0.0110 g.

Co added, g	none	none	0.001	0.005	0.010	0.020
Mn indicated, g			0.0107	0.0103	0.0101	0.0094
Error, mg	0.0	0.0	-0.3	-0.7	-0.9	-1.6

Somewhat better, though still unacceptable, results are obtained as shown in Table II, when the oxidized solution is titrated with sodium arsenite

TABLE II

THE EFFECT OF COBALT IN THE BISMUTHATE-ARSENITE METHOD FOR MANGANESE Weight of manganese added, 0.0110 g.

Co added, g	none	none	0.001	0.005	0.010	0.020
Mn indicated, g	0.0110	0.0110	0.0107	0.0106	0.0102	0.0102
Error, mg	0.0	0.0	-0.3	-0.4	-0.8	-0.8

It may be mentioned in passing that cobalt is not oxidized by persulfate in the hot acid solution which is employed for the oxidation of manganese and that, therefore, good results can be obtained in its presence through the use of the persulfate-arsenite method. For standardization work Ford's method⁹ is to be preferred.

In conclusion, I hope that some reader may be stimulated to investigate various methods for the oxidation of cobalt in acid solution. If the oxidation can be carried to a definite stage we shall, of course, have an excellent method for the volumetric determination of cobalt in the presence of such elements as iron and nickel.

Summary

The proper conditions for the determination of manganese by the bismuthate method are reviewed and the interference of certain elements, notably cobalt, is discussed.

Cobalt is oxidized by bismuthate and the oxidized compound reacts with both ferrous sulfate and permanganate. The latter reaction does not start until some permanganate has been decomposed and then proceeds so rapidly that it causes low results for manganese.

In the presence of cobalt, Ford's method is to be preferred for accurate analyses and the persulfate-arsenite method for routine work.

AZIDO-DITHIOCARBONIC ACID. I. FORMATION, PREPARATION AND PROPERTIES¹

By G. B. L. Smith and F. Wilcoxon with A. W. Browne With Microscopical Studies by C. W. Mason Received August 9, 1923

In view of the readiness with which carbon disulfide reacts with salts of hydronitric acid to form the azido-dithiocarbonates,² it was thought possible that it might react directly with free hydronitric acid to form azido-dithiocarbonic acid, as expressed by the equation

$$HN_3 + CS_2 = HSCSN_3 \tag{1}$$

Formation.—Aqueous solutions of hydronitric acid, when shaken with carbon disulfide for several minutes, or when allowed to remain in contact with this substance for several hours at room temperature, yield solutions in which the presence of azido-dithiocarbonic acid may be demonstrated by treatment (1) with a solution of silver nitrate, which precipitates the explosive silver azido-dithiocarbonate, distinguishable from silver trinitride by reason of its insolubility in ammonium hydroxide; (2) with solutions of iodine and hydronitric acid, the reaction between which is strongly catalyzed, as by a solution known to contain azido-dithiocarbonic acid, and (3) with a solution of mercuric chloride, which yields a white precipitate of the explosive mercuric azido-dithiocarbonate. Anhydrous liquid hydrogen trinitride³ reacts with carbon disulfide to form a light yellow product which in its explosive character and in its mode of decomposition closely resembles azido-dithiocarbonic acid.

From sufficiently concentrated aqueous solutions of an azido-dithiocarbonate, mineral acids precipitate the free azido-dithiocarbonic acid. Dilute nitric or sulfuric acid (1:6) acts in this way, but concd. nitric acid oxidizes the azido-acid first liberated, forming some azido-carbondisulfide as an intermediate product, and finally oxidizing at least a part of the sulfur to sulfuric acid.

- ¹ The investigation upon which this article is based was supported by a grant from the Heckscher Foundation for the Advancement of Research, established by August Heckscher at Cornell University. The present paper is Article No. 1 under Heckscher Grant No. 60. Parts of this paper were presented at the Svedberg Physical Chemistry Symposium held under the auspices of the Rochester Section of the American Chemical Society, January 19–20, 1923, and at the New Haven meeting of the Society in April, 1923.

(d) See also Oliveri-Mandalà, Gazz. chim. ital., 52, II, 139 (1922). This paper was not seen by the authors until after the manuscript of the present article had been submitted for publication.
- ³ The experiments with anhydrous hydrogen trinitride were performed in this Laboratory by Dr. A. E. McKinney and Mr. R. C. Houck, to whom the authors take this occasion to express their appreciation.

Preparation.—A convenient and satisfactory method for the preparation of azido-dithiocarbonic acid involves treatment of 6 g. of recrystallized sodium trinitride, dissolved in a small amount of water, with 6 cc. of purified⁴ carbon disulfide. The mixture is allowed to react in a small, tightly-corked bottle at 40° for about 48 hours. The resulting solution of the azido-salt is filtered, chilled with ice, and treated with cold concd. hydrochloric acid,⁵ which precipitates the azido-acid. The white, crystalline precipitate is washed three or four times by decantation with ice water, is drained on a Büchner funnel and is finally dried on a porous plate. It is preserved over phosphoric anhydride in a desiccator protected from the light, and kept at a temperature below 10°.

Analysis.—The sulfur was determined by oxidizing weighed samples of the azidoacid, first in alkaline solution with bromine, and then with fuming nitric acid and potassium chlorate, finally weighing the sulfur in the form of barium sulfate.

Analyses. Subs., 0.1851, 0.1903: BaSO₄, 0.7278, 0.7422. Calc. for $HSCSN_3$: S, 53.80. Found: 54.00, 53.56.

The nitrogen was determined in accordance with the usual Dumas method by combustion with copper oxide in a stream of pure carbon dioxide. The sample of the acid was mixed with about 20 g. of fine copper oxide and was heated gradually.

Analyses. Subs., 0.1019, 0.1186: N₂, 27.91 cc. (0.03519 g.), 33.08 cc. (0.04170 g.). Calc. for HSCSN₃: N, 35.26. Found: 35.12, 35.16.

The hydrogen was determined by titration of solutions containing weighed amounts of the solid acid with standard sodium hydroxide solution using methyl orange as indicator.

Analyses. Subs., 0.2587, 0.1087: H, 0.00221, 0.00091. Calc. for HSCSN₃: H, 0.846. Found: 0.856, 0.835.

Further evidence confirming the formula assigned to azido-dithiocarbonic acid was obtained by analysis of the silver salt, prepared by treatment of aqueous solutions of the acid with a slight excess of silver nitrate. This white, insoluble substance is highly explosive in the dry state, but may be handled with comparative safety in aqueous suspension. The precipitate was filtered on a tared Gooch crucible, and was dried at room temperature over phosphoric anhydride for 10 days. In weighing the dry salt, suitable precautions were taken to protect the operator from possible injury. The silver azido-dithiocarbonate was dissolved in fuming nitric acid, the resulting solution was evaporated nearly to dryness, and the silver was precipitated and weighed as silver chloride by the usual procedure.

Analyses. Subs., 0.3765, 0.3767: AgCl, 0.2379, 0.2380. Calc. for AgSCSN₂: Ag, 47.73. Found: 47.56, 47.51.

The foregoing analytical results, considered in connection with the data obtained in a study of the decomposition of azido-dithiocarbonic acid, strongly confirm the structural formula assigned to this compound, H—S—C(=S)—N=N=N.

⁴ Ref. 2c, p. 2851.

⁵ Sommer (Ref. 2a, p. 1841) obtained a white precipitate, which he surmised to be free azido-dithiocarbonic acid, by treatment of a cold, concentrated solution of sodium azido-dithiocarbonate with concd. hydrochloric acid. No evidence was submitted in support of this belief, however, and no further work in this direction was reported.

Properties.—Azido-dithiocarbonic acid is a white or very light yellow crystalline solid. It is fairly soluble in water, and is much more soluble in ethyl alcohol, methyl alcohol, diethyl ether, benzene, carbon disulfide, and glacial acetic acid. If the SCSN₃ group be considered as a unit, azido-dithiocarbonic acid may be regarded as a halogenoid hydracid that bears the same relation to azido-carbondisulfide⁶ that hydrochloric acid bears to free chlorine. It may be titrated with a standard alkali solution using methyl orange or methyl red as indicator. By electrometric titration⁶ it has been found to be nearly as strong an acid as hydrochloric acid. Determinations of the molecular weight of the acid in aqueous solution by the cryoscopic method gave results ranging from 72 to 87, which indicate that the compound is highly dissociated, doubtless in accordance with the expression

$$HSCSN_3 \rightleftharpoons H^+ + SCSN_3^-$$
 (2)

Aqueous solutions of azido-dithiocarbonic acid react with various oxidizing agents including, for example, iodine in potassium iodide solution, nitric acid of suitable concentration, ferric chloride, potassium persulfate, hydrogen peroxide, manganese dioxide, and potassium permanganate, with formation of azido-carbondisulfide which appears as a white, microcrystalline precipitate. This formation of the free halogenoid by oxidation of the halogenoid hydracid takes place as expressed by the equation

$$2HSCSN_3 + O = (SCSN_3)_2 + H_2O$$
 (3)

and corresponds with the liberation of chlorine by oxidation of hydrochloric acid.

Azido-carbondisulfide is itself oxidized by the stronger oxidizing agents, and this substance is, therefore, formed only as an intermediate product when the acid is treated with an excess of such substances as concd. nitric acid or potassium permanganate. In these cases the chief final products of oxidation are sulfuric acid, carbon dioxide and nitrogen.

Solutions of such salts of the heavy metals as silver nitrate, mercuric chloride, lead nitrate and copper nitrate, when treated with a solution of the azido-acid yield the insoluble azido-dithiocarbonates, all of which are highly explosive in the dry state. The acid has only a very slight solvent action upon freshly precipitated ferric hydroxide.

Microscopic Examination.—Crystals of azido-dithiocarbonic acid formed on the microscope slide (1) by interaction of a coned. aqueous solution of the potassium salt and coned. hydrochloric acid, and (2) by re-

⁶ See Browne, Hoel, Smith and Swezey, This Journal, 45, 2541 (1923).

⁷ The experimental work on this topic has been carried out by Mr. George H. Brandes, Instructor in Analytical Chemistry at Cornell University. The data will be published in the near future, in connection with an investigation of the electrical conductance of azido-dithiocarbonic acid and certain of its salts, now nearing completion in this Laboratory.

crystallization of samples of the acid previously prepared on a large scale, were found to be identical in appearance.

The simplest setting would place them in the monoclinic system with the forms clino pinacoid (010), basal pinacoid (001) and unit prism (110) represented. The angle β is about 56°. The angle between the prism faces in the basal plane is about 83°. Twinning is frequent on the basal plane.

Double refraction is strong; the extinction angle (clino-pinacoidal view) is about 30°, and the basal view shows parallel extinction. The index of refraction for vibrations 30° to c is estimated at 1.6; for vibrations transverse to this, 1.35+. Such interference figures as were obtainable indicate biaxial character, 2 E large. Z is apparently the acute bisectrix, making the crystals optically positive (+). Probable orientation: $X \land c = 30^\circ$; $Y \perp a$; Z = b.

Contact with a hot wire (below red heat) causes the acid to detonate with a puff of smoke and sulfurous odor, but the detonation is much less violent than that of azido-carbondisulfide. The residue consists of a pale yellow oil from which gas is evolved in considerable amount. Minute prismatic, strongly birefringent crystals, probably of azido-carbondisulfide, showing parallel extinction are a product of the detonation, and are found in colorless masses, vesicular because of the oily material in the interstices. These crystals disappear on standing in contact with the oily material, with evolution of gas, and formation of more oily material. This oil gradually darkens in color and increases in viscosity, with ultimate formation of a red-orange, vesicular, brittle substance, very similar in appearance to the end-product of the decomposition of azido-carbondisulfide.

At room temperature the solid azido-dithiocarbonic acid decomposes slowly, with evolution of gas and formation of a small amount of a fine-grained anisotropic crystalline material together with the yellow oil. Within 24 hours the whole sample is transformed into a yellow, vesicular, tenacious "dough" of viscous material, which after 2 or 3 days becomes brittle and is found to contain no crystalline material.

When brought into immediate, intimate contact with freshly prepared dry azido-dithiocarbonic acid, the yellow detonation product appears to accelerate appreciably the rate of decomposition. This was demonstrated by evaporating a solution of the acid to a crystalline film on a microscope slide. Upon this film was placed a small amount of the coarsely crystalline acid, which was then carefully detonated with the aid of a hot wire. Care was taken to avoid contact between the wire and the microcrystalline film, which as a result of the explosion of the coarse, supernatant material, was spattered with the yellow oil. Wherever this substance came into contact with the undecomposed acid an erosion of the crystals and evolution of gas took place at a rate more rapid than that of the normal, slow decomposition, and quite distinct from the last evolution of gas from the detonation product itself.

The yellow oil obtained as an intermediate product of the decomposition of the azido-acid catalyzes not only the spontaneous decomposition of the acid itself, but also that of the related compound, azido-carbondisulfide. Conversely, the very similar yellow oil obtained from the azido-disulfide catalyzes not only the decomposition of this substance itself but also that of the azido-acid.

Decomposition.—Azido-dithiocarbonic acid is sensitive both to shock and to heat. The dry crystals detonate when broken in a porcelain mortar, when rubbed on a porous plate, or when heated on an asbestos board. The explosion is in no case so violent, however, as that of azido-carbon-disulfide under similar conditions. It is accompanied by the liberation of much heat with considerable smoke and flame, as well as a characteristic odor resembling that of sulfur monochloride.

Below 10° the compound is relatively stable, especially when protected from the light. Even at 0°, however, it undergoes slow decomposition when exposed to the action of daylight. At room temperature, and exposed to diffused daylight, the white or very light yellow azido-dithiocarbonic acid spontaneously passes through a series of color changes which may be formulated as YT1, Y, and OY on the Milton Bradley chart.8 During the course of these changes the dry crystalline material becomes viscous in texture, and puffs up, as a result of the liberation of gas, to several times its original volume. Weighed samples of the acid were found to undergo a loss of weight somewhat in excess of that corresponding to the evolution of 2 atoms of nitrogen per molecule. The presence of appreciable quantities of thiocyanic acid was established by allowing the gaseous products of decomposition to impinge upon filter paper moistened with a solution of ferric chloride. The resulting deep red color was discharged by a solution of mercuric chloride, but not by dil. hydrochloric acid, indicating the presence of thiocyanic acid and the absence of hydronitric acid. Thiocyanic acid vapor accelerates the spontaneous decomposition of azido-dithiocarbonic acid. This was demonstrated by allowing the vapor obtained by treatment of ammonium thiocyanate with dil. sulfuric acid to impinge upon a sample of the azido-acid. It was further shown in unexpected fashion when 5 samples of the solid acid, each of which weighed from 0.5 to 1.0 g., contained in small porcelain crucibles placed close together and covered with one large enamelled iron basin, detonated successively, after shortening time intervals, owing to the increasing concentration of thiocyanic acid in the surrounding atmosphere. The accumulation of the liquid (or solid) products of decomposition in close contact with the still undecomposed portion of the sample also results in greatly decreasing the stability of the azido-acid. Rela-

⁸ Mulliken, "Identification of Pure Organic Compounds," John Wiley and Sons, New York, 1st ed., 1905, vol. I, p. 232.

tively large samples of the compound and samples piled up or closely packed together are more subject to spontaneous explosion than are smaller portions or thin layers, owing to the greater opportunity for adsorption of the catalytic agent in the former case. Such samples have been observed to explode, in some instances even at the temperatures of the ice chest, after the accumulation of catalyst during several hours of slow, spontaneous decomposition.

Very small samples of the azido-acid, heated in open melting-point tubes, appear to melt between 50° and 65° to a yellow oil, in reality a decomposition product, which undergoes further transformation, with evolution of gas and formation of the final orange-yellow solid product. Many samples have exploded under this treatment, sometimes with sufficient violence to shatter the melting-point tube, and in two instances, the thermometer as well. When heated above 70° samples of the azido-acid have almost invariably exploded, usually within a few seconds.

In aqueous solution azido-dithiocarbonic acid undergoes decomposition, with evolution of nitrogen and formation of the usual orange-yellow product which is insoluble in water. The solution becomes turbid at first probably owing to the formation of small amounts of an insoluble intermediate product, rather than to the formation of sulfur, as the substance was found to be soluble in hydrochloric acid. In certain non-aqueous solvents such as carbon disulfide, benzene, and ethyl alcohol, the azido-acid undergoes a similar decomposition with formation, apparently, of the same final product, which is insoluble also in these liquids.

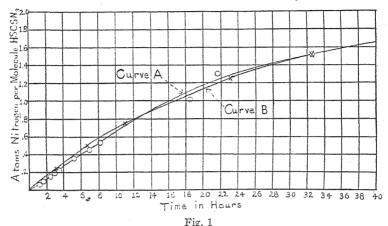

A quantitative nitrometric study of the isothermal decomposition of azido-dithiocarbonic acid in aqueous solution at 25° has been made over a period of about 218 hours, during which the volume of nitrogen evolved was read at frequent intervals. A sample of the solid acid weighing 0.1024 g. and treated in the nitrometer tube with an amount of water just about sufficient to dissolve it, yielded 19.22 cc. (corr.) of nitrogen gas, corresponding to 1.991 atoms of nitrogen per molecule of the azido-acid. The data are shown in part in Fig. 1, Curve A. They indicate that the azido-acid decomposes in aqueous solution at a continually decreasing rate, owing to the diminishing concentration of the reacting substances present in the solution. The differential equation

$$\frac{\mathrm{d}x}{\mathrm{d}T} = 0.04368 (2-x) \tag{4}$$

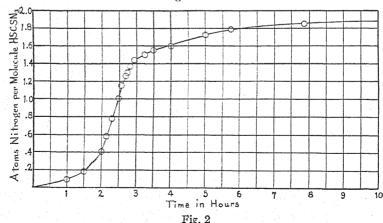

where T is the time in hours, and x the number of atoms of nitrogen evolved per molecule of the azido-acid, expresses the approximate velocity of the reaction. This is the type equation of a simple monomolecular reaction. The integrated form

$$T = \frac{1}{0.04368} \left(\ln \frac{2}{2 - x} \right) \tag{5}$$

makes it possible to calculate the amount of decomposition at any specified time. Curve B, Fig. 1, was plotted from data calculated by means of Equation 5. From the close agreement between the experimental and the calculated data it is evident that the spontaneous decomposition of azido-dithiocarbonic acid in aqueous solution is to be regarded as a simple, monomolecular reaction that shows no effect of catalytic action.

A similar investigation of the isothermal decomposition of the dry azido-acid at $25\,^{\circ}$ covered a period of 48 consecutive hours, during which a sample weighing 0.1055 g. yielded 18.76 cc. (corr.) of nitrogen, or 1.987 atoms per molecule of the acid. The course of the decomposition during the first 10 hours is shown in Fig. 2.

The form of the curve tends strongly to confirm the experimental observations upon the catalytic action of the yellow intermediate product recorded above, and points toward the conclusion that the decomposition

of dry azido-dithiocarbonic acid takes place after the fashion of a monomolecular reaction catalyzed by one of its own products. It has not been found possible to formulate this autocatalytic reaction mathematically by means of the type equation $\mathrm{d}x/\mathrm{d}t = kx(A-x)$, probably for one or more of the following reasons: (1) at least a part of the catalyst is initially evolved as a gas, HSCN, the adsorption and polymerization of which takes place to a degree largely dependent upon the mechanical and physical condition of the sample; (2) the reacting mixture is only partially in liquid form, with the result that its behavior cannot be satisfactorily interpreted in terms of the mass law; and (3) light may exert a catalytic effect upon the reaction as indicated by certain qualitative observations. Further investigation of this topic is in progress.

In the case of the decomposition of the azido-acid in aqueous solution the catalyst is but slightly soluble in water and is, therefore, removed from the sphere of action as soon as it is formed. Very dilute aqueous solutions of the unpolymerized thiocyanic acid seem to exert no appreciable catalytic influence upon the reaction.

It might be argued that at higher temperatures the rapid progress of the exothermic decomposition would maintain the sample of azido-acid at a temperature appreciably above that of the thermostatic bath, thus producing an apparent autocatalytic effect due to the action of heat. At ordinary temperatures, however, the thermal gradient established in this manner may be regarded as negligible, in view of the relatively long period of decomposition, especially in cases where small samples of the azidoacid are used.

Various lines of evidence justify the conclusion that azido-dithiocarbonic acid, both in the dry state and in aqueous solution, decomposes as expressed by the equation

$$HSCSN_3 = HSCN + S + N_2$$
 (6)

This is in conformity with the results of independent investigations of the decomposition of the potassium azido-salt, which yields potassium thiocyanate, sulfur and nitrogen; and of azido-carbondisulfide, from which are obtained free thiocyanogen, sulfur and nitrogen.

The brittle, vesicular, orange-yellow, final product was found¹¹ to be somewhat soluble in hot water, but practically insoluble in cold water. It dissolves readily in solutions of potassium, sodium or ammonium hydroxide. It loses little or no weight when stored for days in a desiccator over phosphorus pentoxide. It is apparently but slightly soluble in ethyl alcohol, acetic acid, and acetone.

⁹ Ref. 2b, p. 2318.

¹⁰ Ref. 6, p. 2543.

¹¹ In connection with this work the authors acknowledge with pleasure the assistance rendered by Mr. D. P Murray.

Four determinations of the total amount of sulfur in both free and combined forms showed an average of 70.18%, confirming the theoretical value, 70.35%, calculated for the mixture (HSCN)_x + xS. The sulfur appears to be very intimately and rather uniformly mixed with the polymerized thiocyanic acid, possibly forming a molecular mixture or solid solution with it. In an attempt to extract the sulfur with carbon disulfide it was found that the extract contained some thiocyanic acid, showing a tendency on the part of this liquid to dissolve or depolymerize the residue. A fair separation was accomplished by digestion of the mixture with a 5% solution of sodium hydroxide. This dissolved the polymerized acid, and left much, though probably not all, of the sulfur undissolved. After removal of the sulfur by filtration, the yellow filtrate was acidified with nitric acid in slight excess, with the result that a heavy orange-yellow precipitate, similar in appearance to the original mixture, was obtained. The percentage of sulfur in different samples of this product was found to vary between 53 and 55%, but the average of several determinations, 54.21%, agrees closely with the theoretical value, 54.26%calculated for thiocyanic acid, indicating that the product is a fairly pure polymerized thiocyanic acid. It probably resembles the substance already described as dithiocyanic acid, H₂C₂N₂S₂;¹² while the orange-yellow solid regarded by the authors as a mixture of free sulfur and polymerized thiocyanic acid shows certain of the characteristics of the substance known as perthiocyanic acid, H₂N₂C₂S₃, 13 or as isopersulfocyanic acid, H₂C₂N₂S₃. 14

Summary

Azido-dithiocarbonic acid, HSCSN₃, a new halogenoid hydracid, has been prepared by treatment of concentrated solutions of the sodium salt with hydrochloric acid. Its composition has been established by analysis, and its crystallographic and optical properties have been studied under the microscope. It is a white or very light yellow crystalline solid, fairly soluble in water, and readily soluble in various non-aqueous liquids. It shows the characteristic properties of a strong acid, and its strength approaches that of hydrochloric acid. It is easily oxidized by various reagents, yielding the free halogenoid, (SCSN₃)₂.

In solid form the acid is sensitive both to shock and to heat. At ordinary temperatures it undergoes spontaneous decomposition at a rate characteristic of reactions of the monomolecular type. This decomposition is catalyzed in the dry state, but not in aqueous solution, by an intermediate product or by the thiocyanic acid formed, and may be expressed

¹² Fleischer, Ann., 179, 204 (1875).

DENSITY AND HYDRATION IN GELATIN SOLS1

By The Svedberg and Bruno A. Stein

RECEIVED AUGUST 11, 1923

Introductory and Theoretical

It is known that in the case of true solution and in colloidal solutions there is more or less combination between the solute or the particles and the solvent or dispersing phase.

Nägeli long ago advanced the idea that solution was a process in which the material was surrounded by a shell of water. Pauli² states, "Crystalloids are said to be hydrated (or, in general, solvated) in solution when water is attached to the dissolved molecules in a stoichiometric proportion. In some instances this hydration is sharply defined (as for sulfuric acid and ferric chloride), but in other cases the hydration is variable and shows a continual alteration with dilution and with change of temperature. We can describe such phenomena with more accuracy as addition of water (or formation of envelopes) by the particles,"

"Such an addition of the medium occurs on the particles of many colloids, and is described as hydration. . . . The indications of hydration of a disperse phase are a disproportionately great viscosity of the solution, a decreased activity of the movement of the particles as displayed in diffusion or in an electric field, and an alteration in volume or density in the direction of compression of the medium." Zsigmondy³ assumes that a density increase must be due to a compression of the particle by its water layer. A contraction in volume when gelatin is dissolved in water is then an evidence of hydration. The varying amount of water in gelatinous coagula shows hydration. Zsigmondy⁴ states that egg white and gelatin must have thicker layers of water than the non-soluble gold and that this assumption probably explains the stability of the former to addition of electrolytes. This exemplifies sols of the hydrophile and hydrophobe type. This author feels that this stability is due to the film of water rather than to the dispersion size of gelatin and gold. Remy also⁵ ascribes a shell of water (Wasserhülle) to the ions of salts in solution.

A high degree of hydration corresponds to a high viscosity in the sol according to Pauli⁶ and Hatschek.⁷ At the iso-electric point of gelatin, at PH about 4.7, a mini-

mum viscosity is observed by Loeb, and it therefore would be also a minimum of hydration. At PH 3.0-3.2 there is a maximum hydration according to the same authority.

As stated above, Pauli explained the decrease in volume, or increase in density, since the two are reciprocal functions, when proteins are dissolved, by assuming hydration of the particles. We picture the particle surrounded by a shell of highly compressed water. Measurements of the density of gelatin sols should give a measure of the degree of hydration. It was thought that if density determinations over a range of Sörensen values should show a maximum for acids at PH 3.2, which corresponds to the point of maximum viscosity, then Pauli's hydration theory would be further verified.

Pauli and Handovsky have shown that salts in general have a depressing effect upon the viscosity of protein sols. This is also true for some organic substances. It was thus hoped to get at the hydration by means of variations in density with different concentrations of acids, salts, and non-electrolytes.

Experimental Part

Approximately $2\ N,\ N,\ 0.1\ N,\$ and $0.001\ N$ solutions of acids were prepared (it was not necessary to have the normality absolutely exact since the Sörensen values were determined later with the hydrogen electrode, these values being tabulated in Table II). Salt solutions were prepared to contain equivalent amounts of chlorine so that $0.1\ N$ sodium chloride contained one mole per liter while N strontium chloride contained 0.5 mole per liter. For the non-electrolytes such as dextrose or glycerol, N solutions were prepared that contained one mole per liter.

Density determinations were made on 5% gelatin solutions which were prepared in the following manner. The material used was a grade A1 gelatin intended for culture media. In order to obtain gelatin containing a constant amount of moisture regardless of humidity changes in the atmosphere, the stock material was dried for two and one-half hours in an electric oven at 50-60°. It was then broken into small bits by passing it through a food chopper. The ground gelatin was kept in a desiccator. For each sample 5 g. was weighed out and transferred into a dry Erlenmeyer flask; 100 cc. of the desired solvent was then measured into the flask with a buret. Solution of the gelatin was effected by holding the flasks at the temperature of the thermostat, 35.2°, and shaking them frequently. The densities were determined with the aid of the Ostwald modification of the Sprengel pycnometer, one arm of which was equipped with a ground-glass cap while the other arm was fitted with a glass tube having a small bulb and bent in the shape of an elbow. With the pycnometer thus fitted, it was entirely submerged in the constant temperature bath, only the tip

⁸ Loeb, "Proteins and Theory of Colloidal Behavior," McGraw-Hill Book Co., New York, 1922, pp. 195-231.

of the elbow tube extending above the surface of the water. The hydrogenion concentrations of the acids were determined by the hydrogen-electrode method using a potentiometer sensitive to 0.2 or 0.3 millivolt.

Method of Calculation

The volume of the pycnometer was determined in the usual way. The density difference, d, was arrived at quite directly: the difference in weight between the pycnometer plus the gelatin sol and the pycnometer plus the pure solvent was divided by the volume of the pycnometer. A concrete example taken from the results will make the statement clearer. For 5% gelatin solution in N hydrochloric acid we find,

N HCl solution + pyc. =
$$50.8212$$
 g,
N HCl + pyc. = 50.4740 vol. of pyc. (27.17565) = $d = 0.012776$
Diff. = 0.3472

An attempt was made to standardize the various steps in the determinations as much as possible. For instance, the time required to weigh out the gelatin was always about the same.

Data and Discussion of Results

Density-difference determinations were made using both electrolytes and non-electrolytes. The former group consisted of acids (acetic, nitric, hydrochloric, sulfuric, and phosphoric) and salts (chlorides of the alkali and alkaline earth metals); the latter group was composed of organic substances such as urea, glycerol, and alcohol. Table I gives the values of d for 5% gelatin in acids of various concentrations as shown.

Table I

The Effect of Acids on the Density Difference
5% gelatin at 35.2°

Conen.	Acetic	Nitrie	Hydrochloric	Sulfurie	Phosphoric
$rac{N}{2}$	0.01395	a	0.01237	0.01145	0.01304
ئے 1	.01440	0.01243	.01277	.01251	.01369
0.1	.01470	.01361	.01356	.01377	01441
0.001	.01470	.01425	.01448	.01435	.01465

 $[^]a$ 2 N Nitric acid coagulated the gelatin; therefore, no determination of the density could be made.

It will be seen that in all cases d increases as the normality becomes less, or as the solution becomes more nearly pure water. The value of d is 0.01443 when only distilled water is used. Apparently all values of d approach that for water, although the values for N, $0.1\ N$, and $0.001\ N$ acetic exceed it.

The hydrogen-ion concentrations of the acids were determined with the hydrogen electrode and are tabulated in Table II as Sörensen values.

Table II
THE SÖRENSEN VALUES OF THE ACID SOLUTIONS

Conen.	Acetic P _H	Hydrochloric Рн	Sulfurie PH	Phosphorie $P_{\mathbf{H}}$
2	1.86	0.03	0.48	1.00
1	2.17	0.45	0.51	1.23
0.1	2.71	0.90	1.07	1.60
0.001	3.55	2.10	2.51	2.67

In Fig. 1 are plotted the values of d on the y-axis against the PH values of the acids on the x-axis. The value of d for pure water is 0.01443 and is plotted at PH 5.4. The first observation is that the density increases with PH and comes to a maximum; the Sörensen value for this maximum is very near to 3.0. From the maximum at PH 3.0, the density curves drop toward a minimum, probably near the iso-electric point. The curves for the variation of density with hydrogen-ion concentration

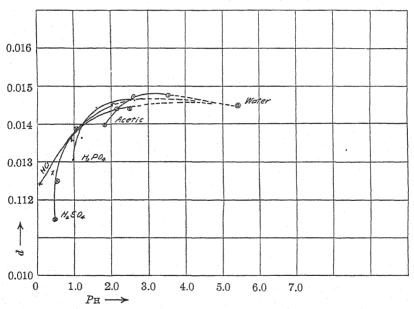

Fig. 1.—Effect of acids on d. The strength of the acids is expressed in Sörensen values would, therefore, in a measure be identical with those given by Loeb⁹ for the variation of total swelling, osmotic pressure, conductivity, and viscosity. The hydration of gelatin increases with the Sörensen value up to or near PH 3.0 as measured by the density of gelatin sols in various concentrations of acids.

If the density increase is due to the formation of a shell of highly compressed water around the gelatin particle, we should expect the density

Loeb, "Theory of Colloidal Behavior," McGraw-Hill Book Co., New York, 1922, p. 38.

to vary with the amount of acid in solution, since there is a contest set up between the gelatin particles and the acid for the possession of the water. ¹⁰ In Fig. 2 the values of d are plotted against the normality of the acids. When this is done, the acids fall (roughly) in the order of their strengths, the acetic and phosphoric coming above hydrochloric, nitric, and sulfuric. The hydration of the gelatin is not as much affected by acetic acid as by

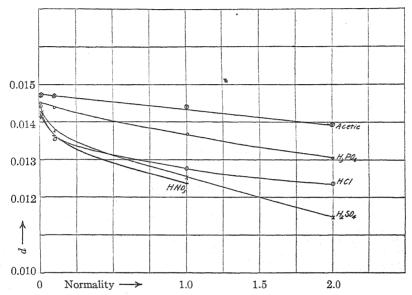

Fig. 2.—The effect of acids on d. The strength of the acid is expressed in normality sulfuric, for instance. From their positions on the graph, we may arrange these five acids in a series as regards their effect on the hydration of gelatin: acetic<phosphoric<hydrochloric<sulfuric and nitric.

In Table III are given the effects of salts on the density difference.

Table III
The Effect of Salts on the Density Difference
5% gelatin at 35.2°

Conen. N	LiCl	KCI	NaCl	CaCl ₂	SrCl ₂
2	0.01201	0.01037	0.01051	0.01004	0.00825
1	.01303	.01222	.01179	.01310	.01063
0.1	.01416	.01363	.01340	.01356	.01321
0.001	.01402	.01376	.01358	****	.01364

The values of d are of the same order as those obtained for the acids. On plotting d against the normality (with reference to the chlorine atom), in the same manner as for the acids, we get the curves of Fig. 3. The

¹⁰ Freundlich, "Kapillarchemie," Akademische Verlagsgesellschaft m. b. h., Leipzig, 1922, pp. 920–978.

value of d for gelatin in water for this series of runs is 0.01365 and is not plotted on the graph to avoid confusion. As the solutions become more dilute, the values of d approach that for pure water in all cases except lithium. It acts anomalously in that d for 0.1 N and 0.001 N solutions exceeds d for water. In the cases of these salts we again have evidence

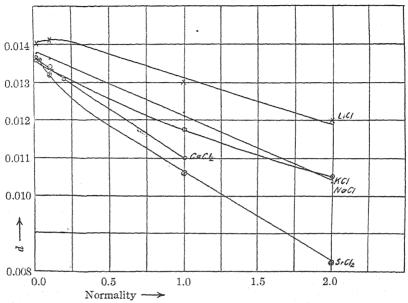

Fig. 3.—Effect of salts on d

of the hydration being affected by a contest between the gelatin and the salt for the possession of the water. An interesting point to note is that the curves for the chlorides of the alkali metals fall above those for the alkaline earth metals and in the order of their absorption on charcoal.¹¹ These cations can be arranged in a series with respect to their effect upon the density: Sr>Ca>Na,K>Li.

Similar density determinations were made on gelatin solutions with various concentrations of non-electrolytes, all organic substances including

dextrose, urea, glycerol, methyl and ethyl alcohol. The results are given in Table IV, and shown graphically in Fig. 4. In general, the organic substances have much less effect on the hydration than do the acids and salts. A curious effect is obtained with the two alcohols: apparently their presence encourages the hydration of gelatin, since the density difference, d, increases with the increase in concentration of the alcohol. The slope of the curves is opposite in sign to those of the acids and salts.

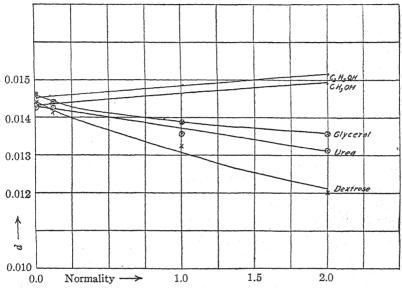

Fig. 4.—Effect of some organic substances

It is interesting to note in connection with the effect of salts and non-electrolytes on the density of the gelatin that Pauli and Handovsky¹² found that the viscosity of acid egg albumin was increasingly depressed by increased additions of salts such as sodium sulfate, sodium nitrate, sodium phosphate, and uranium nitrate. These same authors¹³ find that neutral salts depress the viscosity of alkaline egg albumin and that the salts of the alkaline earth metals are more effective than the salts of the alkali metals. Handovsky¹⁴ also finds that such organic substances as urea, caffeine, glycocoll, and aminobenzoic acid depress the viscosity of protein sols.

Summary

- 1. The variation in density of gelatin sols in different concentrations of acids was determined. It was found that for all the acids used, the den-
 - 12 Pauli and Handovsky, Biochem. Z., 18, 340 (1909).

sity increases with an increase in hydrogen-ion concentration up to a maximum value at about PH 5.0, after which the density curves drop toward a minimum (probably coming at PH 4.7, although more data are necessary before a definite statement may be made).

- 2. The curves for the variation of viscosity of proteins with change in Sörensen values also have a maximum at PH 3.0–3.2 dropping to a minimum at the iso-electric point, PH 4.7, as shown by Loeb and Pauli. The similarity of the density curves to the viscosity curves adds further verification to Pauli's theory of hydration of proteins.
- 3. The acids may be arranged in a series as to their effect on hydration: acetic<phosphoric<hydrochloric<sulfuric<and<nitric.
- 4. It was shown that the effect of alkali and alkaline earth chlorides on hydration is of the same order as for acids and that the cations may be arranged in a series in the order of their effectiveness: Sr>Ca>Na,K>Li.
- 5. Non-electrolytes did not affect the hydration to nearly as great an extent as did the acids and salts. The anomalous action of methyl and ethyl alcohols seemed to indicate that they favored the hydration.

THE DETERMINATION OF TITANIUM BY REDUCTION WITH ZINC AND TITRATION WITH PERMANGANATE¹

By G. E. F. Lundell and H. B. Knowles

RECEIVED AUGUST 18, 1923

Introduction

Most texts leave the impression that the reduction of titanium by zinc in acid solution, as in a Jones reductor,² is a slow and difficult process. As a matter of fact, titanium is no more difficult so to reduce than iron³ and the reduction proceeds quickly and quantitatively to the trivalent stage.

The treatment of the reduced titanium solution is also usually made a matter of special precautions, such as catching the liquid in a measured excess of a standard permanganate solution or in an atmosphere of hydrogen or of carbon dioxide. Here, precautions are well taken, as trivalent titanium is very easily oxidized. The question, therefore, concerns the choosing of the most effective preventive and is answered by the use of

- ² For details concerning the construction of a Jones reductor, consult such texts as Treadwell-Hall, "Analytical Chemistry," Vol. II, 5th Ed., J. Wiley and Sons, p. 638, or Scott, "Standard Methods of Chemical Analysis," Vol. I, 3rd Ed., p. 320.
- ⁸ W. F. Hillebrand in *U. S. Geol. Survey, Bull.*, 700, p. 169, calls attention to this fact and to a communication from Mr. J. A. Holladay, Chief Chemist of the Electro Metallurgical Co., on the same subject.

a solution of ferric sulfate in the receiving flask in the same way that was recommended by Randall⁴ for the determination of molybdenum. The use of permanganate in the receiver is unsatisfactory, as is generally recognized. The maintenance of an atmosphere of hydrogen or of carbon dioxide entails extra labor and expense and is desirable only when both iron and titanium have been reduced and a direct titration of titanium is desired, or when a titanous solution is wanted for volumetric work.

In view of the above remarks and of the increasing use of titanium in various products, it seems desirable to present the following data which demonstrate the ease with which titanium can be quantitatively reduced in a Jones reductor and quantitatively determined by catching the solution under ferric sulfate and then titrating with permanganate.

Experimental Part

A solution of titanic sulfate in sulfuric acid of 5% by volume was prepared from potassium titanium fluoride by repeated crystallizations of the salt, followed by evaporations with sulfuric acid. Tests demonstrated the absence of iron and zirconium and the solution was standardized both by precipitation with ammonia and by cupferron. With ammonia, three precipitations were made and the weighed oxide was freed from silica. The results obtained by the two methods agreed within 1 part in 2000. Weight burets were used in all of the work.

The reductions were made in a reductor having a bore of 19 mm. and a zinc column 43 cm. in length. Our experience has been that satisfactory reduction can be obtained in any reductor which provides a reasonable contact with amalgamated zinc. The reductor was always washed out with dil. sulfuric acid before runs in order to eliminate reducing compounds which are formed as the reductor stands idle. The usual reduction procedure was then followed and there were added in order, 25–50 cc. of dil. sulfuric acid 3–5% by volume, 150 cc. of the same solution containing the titanium, 100 cc. more of acid, and finally 100 cc. of water. The reduction was performed at a speed of approximately 100 cc. per minute or 4 minutes for the passage of all solutions through the reductor.

The reduced solution was caught under a 3-5-fold excess of ferric sulfate⁶

- ⁵ Thornton, Am. J. Sci., [4] 37, 173, 407 (1914). Lundell and Knowles, J. Ind. Eng. Chem., 12, 346 (1920).
- ⁶ Randall (Ref. 4) and various texts prescribe the use of a solution of ferric ammonium sulfate. Our experience goes to show that a sulfuric acid solution of ferric sulfate prepared from ingot iron or plain carbon steel is preferable in that it is less expensive, the absence of ferrous salts and chlorides is assured, and the solution has a clearer color when used alone or with phosphoric acid. Such a solution is made by dissolving the material in aqua regia, evaporating to the fuming point with sulfuric acid, and diluting to proper volume after chlorides have been expelled; 0.02 g. of iron per cc. of 8% (by volume) sulfuric acid is a convenient strength and this will satisfactorily provide for 0.004 g. of titanium.

solution and then titrated with $0.1\ N$ permanganate which had been standardized against sodium oxalate. No phosphoric acid was used in the receiver because of the insolubility of titanium phosphate. All titrations were corrected by careful runs on the reagents and end-point.

The data are given in Table I.

^a Acidity of solution, 3%.

The data in Table I show that a rapid, quantitative reduction of titanium can be had in a Jones reductor, provided the reduced solution is caught under a solution containing at least three times more ferric salt than is necessary to oxidize the reduced titanium. The slight errors average no more than one drop of titrating solution and are undoubtedly due to experimental errors which could be largely eliminated if it were necessary to do so. The data also show that the reduction can be done with sulfuric acid of 3–5% by volume at any temperature between 25° and 100°, that it is not necessary to expel air from the solutions used in the reductor, and that an excess of ferric sulfate must be used in the receiving flask.

When titanium is reduced in the Jones reductor and then titrated as above, it should be borne in mind that the results will be in error if other reducible compounds are present. Such are: certain organic compounds, nitric acid, tin, arsenic, antimony, molybdenum^{III}, iron^{II}, chromium^{II}, vanadium^{II}, tungsten, uranium and columbium. Of these, the effect of

^e Solutions not boiled.

^b Solutions cooled after boiling.

^d Solutions quickly warmed.

the first five is indefinite and depends on experimental conditions; molybdenum, iron, chromium and vanadium are quantitatively reduced to the valences which are indicated; the reduction of the last three is not definite. tungsten approaching the quinquevalent, and uranium and columbium the trivalent state. The list seems large and formidable, but in reality it is not so. Some of the compounds are uncommon and all, save columbium. can be removed with but little effort. For example, it is obvious that nitric acid can be easily removed by evaporations with sulfuric acid and that organic compounds can be destroyed by evaporation with the same acid together with oxidizing agents such as nitric, permanganic or persulfuric acids. The simple remedy for tin, arsenic, antimony and molybdenum is, of course, treatment with hydrogen sulfide in a solution sufficiently acid to prevent hydrolysis of titanium. The elimination of iron is a little more laborious, as it involves three treatments: reduction of the iron by hydrogen sulfide in acid solution, its precipitation by ammonium sulfide in the presence of tartrate, and the removal of the tartrate as outlined above. The separation of titanium from chromium, vanadium, tungsten and uranium is conveniently done by filtration after oxidation in alkaline solution as, for example, with sodium carbonate and sodium peroxide: in this separation, it is to be borne in mind that at first titanium is also oxidized and rendered soluble and that thorough boiling of the solution is necessary to effect its complete precipitation. It is fortunate that columbium is rarely met, as its separation from titanium is a difficult

In conclusion, it is interesting to record that the preparation of titanous solutions for use in volumetric work should not be much more difficult than the task of preparing the corresponding titanic solutions. This follows because any volume of the acidified titanic solution can be run through a Jones reductor and caught in a bottle of suitable size fitted with a 3-hole stopper carrying the outlet of the Jones reductor, and inlet and outlet tubes for maintaining the necessary neutral atmosphere of carbon dioxide or hydrogen.

Summary

The reduction of titanium in a Jones reductor proceeds rapidly and is quantitative, provided the reduced solution is caught under a 3-5-fold excess of ferric sulfate.

The reduction is conveniently carried on in solutions containing 3-5% by volume of sulfuric acid and may be done at any temperature between 25° and 100° .

Attention is called to interfering compounds and their removal, and to the ease with which titanous solutions can be prepared for volumetric use.

STUDIES RELATING TO METALLO-ORGANIC COMPOUNDS. I. INTRODUCTION. II. THE EQUIVALENT CONDUCTANCE OF TRIMETHYLSTANNYL CHLORIDE IN ETHYL ALCOHOL

By Charles A. Kraus and Conral C. Callis Received September 8, 1923

Introduction

The metallo-organic compounds, that is, compounds in which metallic elements appear united with carbon groups, have attracted marked attention within recent years after having passed through a long period of neglect. But even now efforts are directed chiefly towards the preparative side, while the physicochemical properties of these compounds remain largely undetermined. It might be expected that in the metallo-organic compounds the metallic elements function in a manner analogous to carbon in ordinary carbon compounds and that here, if anywhere, substances might be formed which should serve to bridge the gap between inorganic and organic compounds. The present series of investigations was undertaken for the purpose of supplying further knowledge in this field, particularly in relation to the constitution and physicochemical properties of certain of these compounds.

The metallo-organic compounds may be divided into several classes: first, the derivatives of the normal elements of the fifth, sixth and seventh groups; and second, the derivatives of the normal elements of the first, second, third and fourth groups and of certain of the heavier elements of other groups.

The members of the first class of substances are, in general, more stable than those of the second. They may be looked upon as organic derivatives of the normal hydrides of the elements in question, although the hydrides, as a rule, are much less stable than the corresponding organic derivatives.

The elements of this group form mixed compounds in which the valences of the central element may be partially satisfied by hydrogen and partially by hydrocarbon groups. Other mixed compounds may also be formed in which a portion of the valences may be satisfied by electronegative elements or groups. These latter compounds are not, as a rule, very stable, particularly with respect to water, which hydrolyzes them readily. They do not appear to possess salt-like properties in a marked degree. Some of the elements of this group are metallic and others non-metallic and there is nothing to indicate that any marked distinction exists between compounds derived from metallic and those derived from non-metallic elements.

A remarkable property of the members of this group of substances is their power of combining with acids and with the organic halides to form stable compounds of the formula $M''R_{n+1}$ X, in which n is the normal

valence of the element with respect to hydrogen, R is a univalent organic group or hydrogen, and X is an electronegative element. These compounds, which are well known, being represented by the substituted ammonium, sulfonium and iodonium salts, exhibit marked electrolytic properties, in that they are highly ionized in water as well as in practically all other solvents of higher dielectric constant, are conductors of electricity in the fused condition, and yield strong bases. Thus, the substituted ammonium, sulfonium and iodonium bases, as well as the bases of other elements of these groups, are practically as strong as the hydroxides of the alkali metals.

The second group of compounds, derived from the elements of the first, second, third and fourth groups, as well as from certain other heavy elements, may likewise be looked upon as organic derivatives of the hydrides of these elements. But while the hydrides have a relatively low stability, particularly in the case of the less electropositive elements, the corresponding organic derivatives are comparatively stable. These may be divided into two sub-groups, depending upon whether the element in question is strongly electronegative or strongly electropositive. In the case of the strongly electropositive elements such as sodium, the compounds are solids at ordinary temperatures, and exhibit, to some degree at least, electrolytic properties resembling those of the corresponding hydrides in this respect.1 The corresponding compounds of the less electronegative elements are, as a rule, mobile liquids at ordinary temperatures, having low freezing points and exhibiting no electrolytic properties. In a few instances mixed compounds are known in which hydrogen and organic groups both occur. In many instances, too, mixed compounds containing organic groups and strongly electronegative elements or groups of elements are formed, many of which are comparatively stable. However, those compounds containing two or more electronegative elements or groups show a considerable tendency to hydrolyze in the presence of water or other similar solvents.

The most interesting representatives of this series of compounds are those corresponding to the formula $M^nR_{n-1}X$, in which a single valence of the central element is satisfied by a strongly electronegative element or group. These compounds have ordinarily been looked upon as salts, and indeed they exhibit numerous properties common to salts. Thus, solutions of these compounds in water or the alcohols conduct the electric current, while they yield corresponding bases of the type $M^nR_{n-1}OH$, which exhibit marked alkaline properties in aqueous solution. It should be pointed out, however, that these bases are weak when compared with bases of the

¹ Hein, Z. Elektrochem., 28, 469 (1922).

² (a) Bredig, Z. physik. Chem., 13, 303 (1894). (b) Zelinsky and Krapiwin, ibid., 21, 47 (1896).

type M''R_{n+1}OH. Thus, the ionization constant^{2a} of trimethyl tin hydroxide at 25° is 1.7×10^{-7} .

While the compounds of the type $M^nR_{n-1}X$ have ordinarily been classed among the electrolytes or the salts, their behavior, even in solution in various solvents, would appear to indicate that they are not true salts. Thus Zelinsky and Krapiwin have determined the equivalent conductance of triethyl tin iodide in methyl alcohol²⁶ and have found that the solutions are not as highly ionized as are the corresponding solutions of typical salts, while at the same time they conform approximately to the law of mass action. The same is true of diethyl tin di-iodide in the same solvent, which here, however, appears to behave like a binary electrolyte.

The physical properties of the pure compounds do not correspond with those of salts. The mere fact that most of these substances have comparatively low melting points and are comparatively volatile at ordinary temperatures would appear to indicate that they are not true salts. Perhaps the most typical example of substances of this type is trimethyl tin iodide, which is a liquid boiling at about 170° and melting slightly above 0°. The properties of the corresponding bromide and chloride are similar to those of the iodide, the boiling points being somewhat lower and the melting points somewhat higher.

These compounds are characterized by their ready solubility in a great variety of liquids. At ordinary temperatures, trimethyl tin iodide, for example, is miscible (in all proportions) with water, alcohol, ether, acetone, petroleum ether, benzene, toluene, etc. Only in the case of ammonia and various amines does a solid phase appear. In this case, the solid phase consists of a compound between trimethyl tin iodide and the solvent. The nature of the compound here involved will be discussed more fully subsequently.

Compounds of this class do not conduct the electric current in the pure liquid condition. Thus the specific conductance of trimethyl tin iodide is below 0.3×10^{-5} . What the true value of the conductance of this substance is cannot readily be determined, owing to the fact that traces of impurity have a strong influence on its conductance and the purification of these substances is not readily accomplished. The other halides of the trimethyl tin group exhibit properties corresponding to those of trimethyl tin iodide. So, also, amyl mercury iodide in the fused state is a poor conductor of the current. It is probable that all substances of this type are non-electrolytes in the fused condition.

In solution in various solvents the compounds of this type exhibit marked divergence from ordinary salts. In Table I are given approximate values of the conductance of trimethyl tin iodide in different solvents.

An examination of this table will show that while trimethyl tin iodide conducts the current fairly readily in certain solvents, in other solvents it is virtually a non-conductor. Furthermore, there is no relation between the conductance of the solutions and the dielectric constant of the solvent medium. Thus the conductance in nitrobenzene and nitromethane, of dielectric constants 36 and 39, respectively, is little higher than that in ether or benzene. In other words, dissolved in these solvents, trimethyl tin iodide is not an electrolyte. On the other hand, in acetone, pyridine, and the alcohols, trimethyl tin iodide conducts the current fairly readily.

the ionization in general being higher, the higher the dielectric constant of the medium, with the exception of acetone, in which solvent the conductance is markedly lower than even in amyl alcohol although the fluidity of acetone is much higher than that of amyl alcohol. It would appear that the electrolytic properties of solutions of trimethyl tin iodide are due to some specific interaction with the solvent medium. Apparently, those solvents containing basic oxygen or nitrogen atoms form electrolytic solutions. On the other hand, solvents which do not contain basic oxygen or nitrogen atoms yield non-conducting solutions, irrespective of the value of the dielectric constant.

It may be surmised that the electrolytic properties of solutions in the amines and the alcohols and similar compounds are due to the formation of compounds of the ammonium and oxonium type. That this is actually the case will be shown in other numbers of this series.

The Equivalent Conductance of Trimethyl Tin Chloride in Ethyl Alcohol

The work of Zelinsky and Krapiwin, as well as our own preliminary measurements, indicates that the trimethyl tin halides are ionized in

Fig. 1

alcoholic solution, although less than are the corresponding typical salts. It appeared of interest to determine the true degree of ionization of one of these compounds in alcohol, as well as to determine whether or not the law of mass action is here applicable.

Materials and Apparatus.-Trimethyl tin chloride was prepared by chlorinating tin tetramethyl which had previously been purified by treating with ammonia vapor to precipitate any halide present, leaving behind the tin tetramethyl.3 Chlorination is readily effected by leading dry chlorine through tin tetramethyl cooled in ice water with the exclusion of daylight. The trimethyl tin chloride is separated from any excess tin tetramethyl by fractional distillation and is finally purified by successive recrystallizations from low-boiling petroleum ether at low temperatures. The last traces of petroleum ether are removed by means of a vacuum pump.

Trimethyl tin chloride crystallizes in the form of needles melting at 37°.

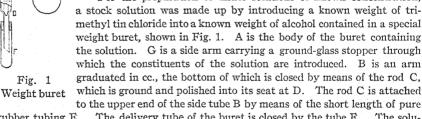

Absolute alcohol was prepared by dehydrating 95% alcohol with lime in the usual way. This product was then treated with freshly dehydrated copper sulfate, 1 kg.

of copper sulfate for 6 liters of alcohol, the whole being heated under a reflux condenser for several days, with a slow stream of air passing through the apparatus. The alcohol was then vaporized with a stream of pure dry air passing through it; about 3/4 of the vapor was condensed and collected for use, the remainder passing by and being later condensed and rejected. By this method, alcohol having a specific conductance of 3.0×10^{-8} was obtained.

The conductance apparatus and thermostat employed were similar to those earlier employed in this Laboratory and described elsewhere in THIS JOURNAL.4

The cell employed was that previously used by Kraus and Kurtz⁵ in this Laboratory; its constant was found to be 0.018286 ± 1 . measurements were carried out at 25.00 ± 1°.

For the preparation of dilute solutions of known concentration, graduated in cc., the bottom of which is closed by means of the rod C,

rubber tubing E. The delivery tube of the buret is closed by the tube F. tion in the buret at no time comes in contact with a lubricated surface. Approximately the desired amount of solution is introduced into the side arm B, after which the end of the buret is introduced into the cell and the liquid in B is allowed to run out by raising the rod C. When all the liquid has run out, the buret is removed from the cell and the cap F replaced, and the amount of solution introduced into the cell is determined by reweighing the buret. This apparatus has been found extremely useful in handling liquids which dissolve stopcock lubricant.

The cell was removed from the bath after each addition of solution, and the contents were thoroughly mixed. The cell was then returned to the thermostat and conductance

measurements made at intervals until a constant value was reached. This procedure was repeated until check readings were obtained. At the lower concentrations, a slow change in the value of the conductance took place with time, which rendered these observations somewhat uncertain. At higher concentrations, this effect was not observed; it was greatly accentuated in case the specific conductance of the alcohol was high. In the case of the iodide the effect was much more pronounced than in that of the chloride and could not be overcome at the time.

Experimental Results.—In Table II are given the results of a series of measurements with trimethyl tin chloride at 25° . The specific conductance of the solution given in the second column has been corrected for the specific conductance of the solvent, whose value is given at the head of the table. The equivalent conductance is given in the third column and the mass-action function, $K \times 10^4$, in the last column.

Table II Conductance of Trimethyl Tin Chloride in Absolute Alcohol at 25° 347.37 g. of absolute alcohol. Specific conductance, l, of alcohol = 0.305×10^{-7} . Cell constant, 0.018286. Solution added contained 4.83% of (CH₃)₃SnCl by weight

8.9449	167.47	1.87	.356
16.5707	234.09	1.41	.369

Discussion.—The results are shown graphically in Fig. 2, values of $1/\Lambda$ being plotted as ordinates and values of the specific conductance as abscissas. If the law of mass action is applicable, the experimentally determined points, according to this plot, should lie on a straight line, the intercept of which on the axis of ordinates yields the value of $1/\Lambda_0$ and the slope of which gives the value of K/Λ_0^2 , from which the value of K may be determined.

An examination of the plot will show that, with the exception of two or three determinations at higher concentrations, the points lie on a straight line practically within the limits of the experimental error. This is also indicated by the value of the mass-action constant as given in the last column of Table II. The plot yields for Λ_0 the value 30.8, and for K the value 0.349×10^{-4} .

It is evident that the law of mass action holds very nearly up to a concentration of 10^{-3} equivalents per liter, while at higher concentrations there is a slow deviation in the same direction as in the case of ordinary electrolytes in solvents of higher dielectric constant. This electrolyte in

alcohol, therefore, resembles moderately weak acids and bases in water and moderately strong acids in alcohol. This is a striking fact, inasmuch as it is practically the first instance of an electrolyte, other than an acid or a base, which has been shown to conform to the law of mass action in solvents of higher dielectric constant.

Heretofore, the only weak electrolytes known have been the acids and bases. It appears, however, that, in general, compounds of the type $M^nR_{n-1}X$ are comparatively weak electrolytes.

Actually, the compounds of this type have many properties in common with the acids. As has already been pointed out, in the pure liquid state they are indifferent conductors of the electric current. In solution they

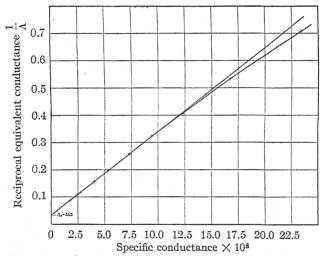

Fig. 2.—Approach of conductance values to the mass-action relation of solutions of $(CH_3)_3SnCI$ in absolute alcohol

act as electrolytes only when dissolved in solvents of the basic type, such as ammonia, water, etc. This is also true of the acids. In the case of the acids, the conductance is accounted for on the assumption that a compound of the type $M^nH_{n+1}X$ is formed between the acid and the solvent. As will later be shown, the compounds of the type $M^nR_{n-1}X$ likewise combine with solvents of the ammonia and water type to form new compounds of the type $M^nR_{n+1}X$. These compounds, therefore, so far as their physicochemical properties are concerned, may be classed with the acids.

That this should be the case is not unexpected, as has been pointed out by one of the authors.⁶ The behavior of an element, or a group of elements, in its compounds with other elements or groups, is determined by its position in the potential series. A strongly electropositive group combined

⁶ Kraus, Rec. trav. chim., 42, 588 (1923).

with a strongly electronegative element or group yields an electrolyte, that is, a compound which is ionized in the pure state as well as in solution. As the electropositive constituent becomes less electropositive, the electrolytic properties of the resulting compound become less pronounced, the specific conductance of the pure substance in the liquid condition diminishes and its ionization in solution, under otherwise comparable conditions, likewise diminishes. When the electropositive constituent lies somewhere near the middle of the potential series, in other words, when its position corresponds with that of hydrogen, the compound will exhibit practically no electrolytic properties, or only weakly electrolytic properties in the pure state and, in general, will not exhibit electrolytic properties in solution. Only in case the group is capable of associating itself with the solvent, or some added substance, to form a new and more electropositive group will solutions of these compounds exhibit electrolytic properties.

That a group of the type of the trimethyl tin group lies intermediate in the potential series is further shown by the fact that this group forms a stable negative as well as positive ion. In fact, compounds in which this group acts electronegatively are probably true salts. Thus, compounds of the type (CH₂)₃SnNa may readily be formed, and these compounds exhibit marked electrolytic properties in solution and in general behave like salts. Such compounds will be discussed more fully in a succeeding article.

Summary

- 1. The metallo-organic compounds corresponding to the formulas $M^nR_{n+1}X$ and $M^nR_{n-1}X$ exhibit electrolytic properties, but only the members of the first class are true electrolytes. The members of the second class exhibit electrolytic properties only under particular conditions.
- 2. Data are given for the conductance of trimethyl tin iodide in the pure state and in solution in various solvents. The pure compound is a poor conductor, while solutions of this compound in solvents of the non-basic type are likewise poor conductors, even though the dielectric constant of the solvent may be high. Solutions in the alcohols and the amines are relatively good conductors.
- 3. The equivalent conductance of trimethyl tin chloride in absolute alcohol at low concentrations has been measured. From these measurements the value 30.8 is deduced for Λ_0 . Up to a concentration of 10^{-2} N, the conductance values conform to the law of mass action within the limits of the experimental error. The mass-action constant has the value 0.349×10^{-4} .
- 4. The properties of compounds of the type of trimethyl tin chloride are discussed. It is suggested that the electrolytic properties of solutions of this and similar compounds in the alcohols and the amines are due to

the formation of a more electropositive group by combination of the trimethyl tin group with the solvent. It is pointed out that the properties of trimethyl tin chloride correspond closely to the properties of methyl iodide and more particularly to those of the halogen acids.

5. The properties of the trimethyl tin group and of its compounds may be accounted for on the basis of the electro-affinity of this group. The analogy which this group bears to hydrogen is pointed out.

THE FREE ENERGY AND HEAT OF FORMATION OF LEAD MONOXIDE

By David F. Smith¹ and Hubert K. Woods Received September 11, 1923

Introduction

The purpose of this investigation was to determine the change in the free energy and heat content when lead oxide (PbO) is formed from its elements at 25°.

Apparently no measurements have yet been made from which the free energy of lead oxide may be accurately obtained. High-temperature equilibria would doubtless be complicated by the formation of other oxides of lead and always involve a more or less unreliable extrapolation to standard temperature on account of inaccurate heat data. Lewis and Randall² have attempted to calculate the free energy of lead monoxide from solubility measurements and molal free energies but obtain a very uncertain value. As the results of Berl and Austerweil³ show, in solutions of lead monoxide there is considerable formation of complex ions such as PbOH+, so that the activity of the lead ion would be difficult to estimate even in very dilute solutions. Lewis and Randall² have also pointed out the probable uncertainty in the thermochemical value of the heat of formation of lead monoxide and the excessive discrepancy between their approximate value of its free energy and that obtained by using low-temperature specific-heat data, heats of reaction, and the constant entropy principle (the so-called "third law of thermodynamics").

Since lead oxide is only slightly soluble in dilute alkaline solutions, a measurement of the electromotive force of cells such as $H_2(g)$ | dil. alkaline solution | PbO(s) + Pb(s) should give directly a measure of the free-energy change in the reaction $H_2(g)$ + PbO(s) = Pb(s) + H_2 O(l). A combina-

tion of the electromotive-force measurements with the known value of the free energy of liquid water would give the free-energy content of 1PbO(s).

In view of the unreliability of the thermochemically determined heat of formation, we have obtained the heat of the above reaction from the temperature coefficient of the electromotive force of the above-mentioned cells. This, when combined with the known heat of formation of liquid water, gives the desired heat of formation. The possession of the requisite low-temperature specific data, together with the free energy and heat of formation of lead oxide permits a further test of the "third law."

This research was carried on in part with the aid of a grant made to Professor A. A. Noyes by the Carnegie Institution of Washington, for which the authors wish to express their indebtedness.

Preparation of Materials and Solutions

We prepared for use in our cells red lead monoxide, which is the stable form at ordinary temperatures.⁴ The yellow oxide and also the hydroxide, in contact with alkaline solutions, slowly change over to the stable red form. A fine, crystalline, dark red oxide was obtained by slowly adding crystals of pure lead acetate to a boiling, concentrated solution of sodium hydroxide from which the carbonate had been removed by the addition of a small amount of barium hydroxide. The oxide thus obtained was thoroughly washed with water and dried in a vacuum over sulfuric acid.

Lead was plated on platinum spirals from a solution of pure lead oxide in strong perchloric acid containing a small amount of Witte's peptone. This gave a light gray, closely-adhering deposit free from occlusions. Finely divided lead was prepared by fusing pure lead carbonate with pure sodium cyanide in a porcelain dish, and filing the button thus obtained.

Barium hydroxide solution was used as electrolyte, since it is more easily obtainable pure than are the alkali hydroxides and also because it remains free from dissolved carbonate. The solution was made from a high grade of the pure crystallized salt of commerce.

Air was carefully excluded from all solutions and from the cell by the use of glass flasks fitted with sealed-on outlet tubes and connected to a supply of nitrogen.

Apparatus

One of the chief difficulties experienced with cells which depend upon the saturation of a solution with a solid lies, we believe, in the slowness of the approach to saturation and of the removal of oxygen. This can, however, be obviated by efficient stirring of the solution. We have, therefore, used an automatic pump which saturates and stirs the solution di-

⁴ For a discussion of the relative stabilities of the various forms of lead oxide, their solubilities, etc., see Abegg, "Handbuch der anorganischen Chemie," S. Hirzel, Leipzig, 1909, III [2] 673 ff. and 677 ff.

rectly in the cell without contact of the solution with air or with other than glass apparatus.

The complete cell, with the circulating pump attached, is shown in Fig. 1.

Referring to the diagram, the glass tube CC is fitted with an inner tube BB in which slides a loosely-fitting plunger P consisting of strips of transformer iron completely enclosed in a glass tube. When the electromagnet AA is energized (by an automatic current-interrupter not shown in the figure) the glass plunger P rises rapidly, forcing the liquid which completely fills the interior of the apparatus, up through the inner tube and down the annular space between CC and BB, out at D, through the glass wool plug E, through the mass of lead and lead oxide at F, out again through the glass wool plug at the top and side of the lead cell T, opening the float valve H which is ground to a seat

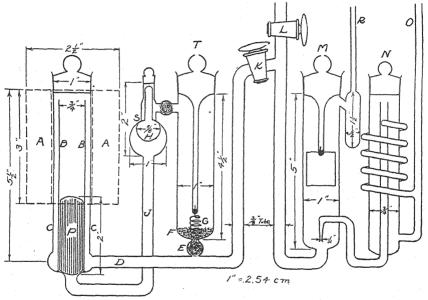

Fig. 1

at S, down the tube J and back to the bottom of the plunger P. The current through the electromagnet having been broken, the plunger P slowly sinks to the bottom of the tube BB allowing the solution to pass between it and the walls of the tube, the reseating of the float valve H preventing backward flow of the liquid. The cycle is repeated at intervals of 5 or 6 seconds, pumping about 6 cc. of solution per stroke. In a short time this whole section of the apparatus is filled with a fine silt of the oxide which exposes a large surface and quickly saturates the solution.

The hydrogen saturator and half-cell are shown at the extreme right of the figure. The hydrogen, entering at O, passes around the spiral in small bubbles which emerge from the top of the spiral, the solution returning to the reservoir N and the gas passing through the central tube and into the hydrogen cell M. This type of saturator gives long contact of the gas with the liquid, avoids spray, circulates the solution in the reservoir, and offers little back pressure to the hydrogen generator. The trap at the bottom of the outlet tube R prevents moisture condensed from the escaping hydrogen from flowing back into the cell.

The hydrogen for the cell was generated by electrolysis of a potassium hydroxide solution contained in a U-tube, the oxygen electrode of which was placed well up in the side arm to prevent diffusion of oxygen over to the hydrogen side. The hydrogen passed over a platinum coil electrically heated to redness to remove traces of oxygen, and over phosphorus pentoxide to remove water, then through a fine capillary tube which regulated the flow of hydrogen through the saturator and cell.

The cells were kept in a bath of light oil (commercially known as "Transil Oil"), the temperature remaining constant to 0.02° as determined by a thermometer calibrated by the Bureau of Standards.

The electromotive forces were measured with a potentiometer of a modern type against a Weston standard cell.

Measurement of the Electromotive Forces

We were careful to avoid the use of the lead obtained by electrolysis in the form of "lead tree," since this type of deposit is hard to wash free from traces of impurities and doubtless contains much occluded salt from the electrolyzing bath. The presence of carbonate is also undesirable, for although lead carbonate is very slightly soluble in water, it is doubtless somewhat soluble in alkaline solutions. Thus, when lead acetate solution was added to a solution of commercial sodium hydroxide there was no precipitate of lead carbonate, while barium carbonate precipitated in considerable amount when a solution of barium hydroxide was added.

The individual cells were run for a period of several days. They showed variations of less than 0.1 mv. for many hours after the cells had come to equilibrium. Each cell was alternately pumped out and allowed to stand until finally further pumping produced no change in the measured electromotive force.

The lead half-cell contained an excess of solid lead oxide mixed with finely divided lead, contact with which was made through platinum leads plated with lead as previously described.

Final values of the measured electromotive forces are presented in Table I. The headings are for the most part self-explanatory. The

TABLE I
OBSERVED ELECTROMOTIVE FORCES

		· ODDALK!	~~ ~~~~~		re out to

hydrogen pressure given has been corrected for the observed barometer reading, the vapor-pressure of water at the respective temperatures, and a head of 1 or 2 cm. of water above the electrodes in the hydrogen half-cell. Each value of "e.m.f. observed" is the value obtained for a separate filling of the cell with new solution and materials.

Calculations

From the "best values" of our electromotive forces we find for the reaction PbO(s) + H₂(1 atm.) = H₂O(l) + Pb(s) the following free energy values: at 298.1° K., $-\Delta F = 11,509$ cal.; at 318.1° K., $-\Delta F = 11,214$ cal. Taking the free energy of H₂O(l) at 298.1° K. as -56,560 cal., we calculate the free energy of PbO(s) at this temperature to be -45,050 cal. The difference between the free energy of pure water and that of water in the barium hydroxide solutions is hereby neglected; but this is permissible, since the vapor pressure of even a 0.25 molal solution certainly does not differ from that of water by more than 2%; and this corresponds to a free-energy difference of only 12 calories.

This free energy of lead oxide differs by about 4000 cal. from the value (—41,000 cal.) previously derived by Lewis and Randall from available solubility data for lead oxide and the electrode potentials of lead and oxygen.

Using the integrated Gibbs-Helmholtz equation, $\frac{E_2}{T_2} - \frac{E_1}{T_1} = \frac{\Delta H}{NF} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$

whereby ΔH is assumed constant over the temperature interval involved (ΔC_p is only 6.0 cal. per degree), and substituting our measured electromotive forces, and the temperatures 318.1° and 298.1°, we calculate ΔH for the above reaction to be equal to —15,910 cal. Taking the heat content of liquid water at 25°C. to be —68,270 cal., 6 we calculate the heat of formation of PbO(s) from its elements at 25°C. to be —52,360 cal.

To obtain ΔH as a temperature function, this value of the heat of formation of 1 PbO at 25° may be combined with the following expressions for the heat-capacities at constant pressure: for 1 Pb, 6.01 + 0.00085 T + 0.00000154 T^2 ; for 1 PbO, 11.58; for $1/2O_2$, 3.25 + 0.0005 T. The expression for 1 Pb is derived from the values of the specific heats, 0.03083 at 18° and 0.03155 at 100°, obtained by Jaeger and Diesselhorst⁷ and the value 0.03380 at 300° obtained by Naccari.⁸ The expression for 1 PbO is derived from the value of the specific heat 0.0519 at 23° obtained by Russel,⁹ and that for $1/2O_2$ is taken from Lewis and Randall.¹⁰ These lead to the following expressions for the heat-content and free-energy increases ac-

⁵ Ref. 2, p. 485.

⁶ Ref. 2, p. 477.

⁷ Jaeger and Diesselhorst, Wiss. Abh. Phys.-Techn. Reichsanst., 3, 269 (1900).

⁸ Naccari, Atti acad. sci. Torino, 23, 107 (1887-88).

⁹ Russel, Phys. Z., 13, 59 (1912).

¹⁰ Ref. 2, p. 80.

companying the formation of 1 PbO from its elements at temperatures between 0°C., and the melting point of lead (327°C.):

$$\Delta H = -52,980 + 2.32 \ T - 0.000675 \ T^2 - 0.000000257 \ T^3$$

 $\Delta F = -52,980 - 2.32 \ T \ln T + 0.000675 \ T^2 + 0.000000128 \ T^3 + 39.62 \ T$

Lewis and Randall (Ref. 2, p. 497) give the value of $T\Delta S$, calculated from low-temperature specific-heat data with the aid of the constant entropy principle for the reaction Pb + $^{1}/_{2}O_{2}$ = PbO at 25°C. as —6900 cal. Subtracting this value from our value for the heat of formation of lead oxide we calculate the free energy of lead oxide at 25° to be —45,460. This value is 410 cal. less than the more accurate value based upon our electromotive-force measurements; but this is about the usual order of agreement between the free-energy value calculated upon the assumption of the constant-entropy principle and that obtained by chemical methods. 11

Summary

- 1. An apparatus has been described for effectively saturating and stirring the electrolyte in a cell, thereby decreasing greatly the time taken for a cell containing a solid salt to come to equilibrium.
- 2. Electromotive-force measurements upon the cell, $H_2(g) \mid Ba(OH)_2$ (0.0766–0.2242 M) | PbO(s) + Pb(s), give the free energy of PbO(s) as —45,050 cal. at 25°, when the free energy of liquid water at this temperature is taken as —56,560 cal.
- 3. From the temperature coefficient of the electromotive force of this cell the heat of formation of PbO(s) at 25° is calculated to be —52,360 cal. when the heat of formation of liquid water at 25° is taken as —68,270 cal. Temperature-functions for its heat-content and free energy have been derived.
- 4. From the above value for the heat of formation of PbO(s) and the value of its entropy of formation derived by Lewis and Randall from the constant-entropy principle, the free energy of PbO(s) at 25° is found to be —45,460 cal., which is as close to our more accurate experimental value as are most of the free energies computed by this method.

THE ADSORPTION OF MIXED GASES BY CHARCOAL. I. CARBON DIOXIDE AND NITROUS OXIDE

By Leon B. Richardson and John C. Woodhouse Received September 15, 1923

While the adsorption of single gases by charcoal has been the subject of extensive investigation, similar studies for mixtures of gases have been much less abundant. Bancroft1 states that such work as has been done "indicates that the more readily adsorbed gas displaces the other to some extent, and is adsorbed to a greater relative amount than one would have predicted from experiments on the single gases." The experiments which led to this deduction were, however, largely qualitative; or where quantitative, were carried on at low pressures. Thus Bergter2 investigated the adsorption of nitrogen and oxygen mixtures at very low pressures and Hunter.3 that of a number of easily condensable gases which probably dissolved in one another; Lemon and Blodgett, working at the temperature of liquid air, studied the rate of adsorption of nitrogen-oxygen mixtures; and Miss Homfrav⁵ worked with mixtures of carbon monoxide and nitrogen at -79°. In all these cases, however, the pressures were low and extended through a very limited range; the temperatures were also low; nor was any attempt made to determine the adsorption of the separate gases in the mixture at a number of pressure points. It seemed worth while, therefore, to investigate the total adsorption of gaseous mixtures at 0° through pressures ranging from very low values to a maximum of 3.5 atmospheres, and also to determine at numerous pressure points, by methods of analysis, the adsorption of each gas separately. Carbon dioxide and nitrous oxide were selected as materials for the first study. It is hoped that other pairs of gases will form material for subsequent papers from this Laboratory upon the same general problem.

Materials and Apparatus

Charcoal.—As an adsorbent, steam-activated charcoal⁶ was used. Its density determined in a vacuum in the usual way gave results 1.809 and 1.806. The ash content was 1.87%. The pieces were 8-10 mesh size, and the same sample, weighing 4.5332 g., was used throughout the determinations. The material was highly adsorbent, and took up each time, even after extensive use, nearly the same amount of a given gas.

Gases.—In the selection of gases the following conditions were considered desirable.

(1) The gases should not react upon each other or upon the charcoal. (2) They

should not, when liquefied, dissolve appreciably in each other. (3) They should be adsorbed to a large extent at 0°. (4) They should be of nearly equal density, to insure quick and easy mixing. These requirements seemed to be met by the selection of carbon dioxide and nitrous oxide. The adsorption of the first has been widely studied; its isotherms have been repeatedly determined. Very little work has been done on the second, but from its physical constants and from the results of Hempel and Vater' it is apparent that its degree of adsorption is comparable to that of carbon dioxide. The only point that caused apprehension was that at the temperature required for out-gassing (425°) the charcoal might be oxidized by the nitrous oxide. Consequently, an analysis of the gas subjected to the action of the charcoal during the out-gassing process was made in each determination of the nitrous oxide isotherm. In no case was the slightest amount of carbon dioxide detected in the gas withdrawn from the cell; nor in the runs of mixed gases was any excess of carbon dioxide over that introduced into the system ever obtained.

The carbon dioxide used was 99.7-99.9% absorbable in potassium hydroxide solution. The nitrous oxide was a commercial product which by analysis was shown to be 98.4-99.1% pure, the sole impurity appearing to be nitrogen. It is difficult to prepare nitrous oxide in sufficient quantities by the ordinary processes of the laboratory of as high purity as this. As the influence of the small quantities of contaminating nitrogen was slight, and as its precise effect on the isotherms could be determined, the gas as procured was deemed sufficiently good for the purpose of these experiments.

Method of Determining Isotherms.—The adsorption isotherms of the mixture were made by running known quantities of the gases into a cell containing the adsorbent. When the maximum pressure was reached the points on the isotherm were determined by withdrawing successive portions of the mixture and analyzing each portion withdrawn. The system was allowed to come to equilibrium and the pressure read after each withdrawal. The apparatus having been carefully calibrated, the volume of the gaseous phase could be determined from the pressure reading, while the volume of each of its components could be obtained by the analysis of the gas withdrawn. The total volume of each gas admitted to the apparatus being known, the volume adsorbed, both total gas and each component, could be determined by difference.

Apparatus.—The apparatus used in the determinations was of the type employed by one of us⁸ in the determinations of the individual isotherms of carbon dioxide and ammonia. It was modified in such details as became necessary through the use of more than one gas, and of their withdrawal for analysis. A diagram of the essential parts is given in Fig. 1. Cell C contains the charcoal, and is connected on one side with the manometer M capable of registering pressures to 3000 mm., and on the other, through the 3-way stopcock A to the 100cc. water-jacketed buret B. To the right, the gas buret is joined through the 3-way stopcock D to the gas supply tubes E and E'. All connecting tubing is of 1 mm. bore, and all connections are made by fusing the glass together.

Carbon dioxide, dried by being passed through a calcium chloride tube and two Friedrichs wash bottles filled with sulfuric acid, was introduced through E. Nitrous oxide, first bubbled through two large Winkler bulbs filled with sulfuric acid, was brought in at E'. This tube also served for the withdrawal of gas and its transfer to the analysis apparatus. If the gas was not required for analysis it was run out through the mercury trap F. By the manipulation of the stopcock A and the mercury-filled leveling bulb L, gas could be pumped into the cell up to high pressures, or out of it through F until a vacuum was obtained. The leveling bulb could be raised by a wire running through a pulley in

⁷ Hempel and Vater, Z. Elektrochem., 18, 724 (1912).

⁹ Richardson, This Journal, 39, 1829 (1917).

the ceiling so that the maximum pressure could be easily secured. After exhausting the cell, gas could be drawn in through E or E', measured under known conditions of pressure and temperature in the buret, and then forced into the cell.

The buret was calibrated in duplicate by weighing its water content. The volume of gas in the manometer at various mercury levels was determined by sealing off the capillary tube connecting the cell with the apparatus and passing in successive volumes of carbon dioxide measured in the buret. Three calibrations were made, the maximum divergence being 0.4%.

The cell was constructed as shown in Fig. 1. Tube a has an internal diameter of 9 mm.; Tube b, 4 mm.; Tube c, 1 mm. The capacity of the cell to the point f was determined thrice with a maximum variation of 0.13%. The volume from e to f was also obtained. The weighed sample of charcoal was introduced through b, and the cell was then sealed off between e and f, care being taken to make a very flat end, thus avoiding any uncertainty of measurement caused by a conical tip. By measurement from e to the end, the fraction of the known volume (e to f) then in the cell could be calculated. The small free space in the capillary above the level f was ascertained by calibration of

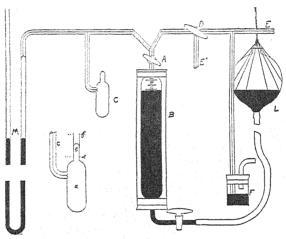

Fig. 1

other pieces of the same tubing. The total volume of the cell thus obtained was 8.45 cc. The volume of the charcoal in the cell, determined from its weight and density, was 2.51 cc. The free space in the cell was thus 5.94 cc. The tubing of the apparatus was cut off at a measured distance above the point at which it was sealed during the manometer calibration, and the volume thus removed was subtracted from that calibration. The volume of capillary tubing from point e to the point at which the fused joint was made was also calculated and added to the cell volume. The volume of the gas in the cell at various pressures (corrected in accordance with the data of Regnault) and at a temperature of 0° was added to the volume of gas in the manometer at the same pressures and at the temperature of the manometer calibration ($20^{\circ} = 1^{\circ}$). These total volume results were plotted, and from the curve obtained the volume of the gaseous phase could be read at any pressure registered by the manometer.

As all determinations were made at 0°, temperature regulation was effected by a bath of finely divided ice and water. The variation was less than 0.1°. The thermometers used in determining the temperatures of the bath, the manometer, and the buret were checked against one another and against a standard thermometer graduated to 0.1°.

Analysis

The successful prosecution of the work required an accurate method for the analysis of mixtures of carbon dioxide and nitrous oxide. The ordinary methods, namely, absorption of carbon dioxide in potassium hydroxide, and the explosion of nitrous oxide after mixture with a measured volume of hydrogen, are accurate enough for each gas separately but require modification when the gases are mixed. The difficulty lies in the solubility of nitrous oxide in the potassium hydroxide, which is sufficiently great under ordinary circumstances to vitiate the process. It was necessary, therefore, to determine just how much nitrous oxide is dissolved in solutions of potassium hydroxide of various concentrations. It was found that although solutions of the alkali of concentrations usual in gas analysis (30-40%) do dissolve sufficient amounts of nitrous oxide to make the separation inaccurate, a 55% solution, after the first exposure of nitrous oxide to it, takes up only inappreciable amounts of the gas. Fresh solution of this concentration placed in contact with 100 cc. of nitrous oxide for three hours dissolved only 1.4 cc.; a much smaller amount than is taken up by alkali solutions of lower concentrations. After this exposure of the fresh potassium hydroxide solution, nitrous oxide was again placed over the solution for the period of 10 minutes or so customary in gas analysis, and also for longer periods, both alone and mixed in various proportions with carbon dioxide. In no case was any nitrous oxide given off from the liquid or any more dissolved by it. This decrease of solubility is in accord with the results of Geffcken⁹ although his work was not carried to such high concentrations of alkali. Extrapolation of his figures gives solubilities of nitrous oxide in potassium hydroxide solutions very close to those here obtained.

Attention should be called to two precautions necessary in the ignition of mixtures of nitrous oxide and hydrogen which are not mentioned in the texts on gas analysis. Incomplete mixing of the two gases not infrequently causes feeble explosions. The gases should be passed from the buret to the pipet and back several times. Even more important is the necessity for the presence of a small amount of water (0.5–1 cc.) in the explosion pipet. Again and again, in cases in which it had been found impossible to initiate an explosion when the gases were dry, the spark became thoroughly effective after the addition of this small quantity of water. Consequently, assurance of the presence of water was finally made a matter of routine practice in the analysis.

Variations in the volume of gaseous mixtures from the sum of the volumes of the component gases before mixing may also have an effect upon the results. Fuchs¹⁰ presents data covering various mixtures; among others,

⁹ Geffcken, Z. physik. Chem., 42, 257 (1904).

¹⁰ Fuchs, ibid., 92, 641 (1918).

carbon dioxide and nitrous oxide. His results seem to show that a 50–50 mixture of these gases occupies a volume 1.42% greater than the sum of the volumes of the individual gases. Investigations of our own showed that the expansion, in this case at least, is approximately that indicated by Fuchs. From his data, therefore, a graph was drawn which indicated what this variation should be for all proportions of mixtures of the gases in question, and what corrections should be made in each analysis. It should be said, however, that this correction exercises so slight an influence upon the final result as to make its effect almost negligible.

Experimental Procedure

The amount of gas adsorbed by charcoal is dependent upon many seemingly unimportant factors. Slight variations in conditions produce relatively great variations in results. If values are to be duplicated, the process must be standardized and, when thus standardized, accurately followed. This done, as described below, no difficulty was found in obtaining close duplicates of the isotherms, both of single gases and of each mixture with which experiments were made.

To prepare the charcoal for the adsorption, the cell was heated to 425° by an electric furnace, gas being pumped out at frequent intervals as it escaped. In the course of four hours the pressure was reduced to not more than 1 mm., even at the high temperature. The cell was then cooled slowly (20 minutes) to 0°, and allowed to remain for 10 minutes at this point before any gas was run in. In the meantime gas, carbon dioxide or nitrous oxide, as might be desired, was being passed in through E or E' and out through F, so that residual gas might be removed from that part of the apparatus. The two gases were then admitted to the buret in such proportions as might be desired, and mixed by raising and lowering L several times. The amounts run in were such that their total volume would equal the capacity of the buret, and in the proportions which were desired in the final mixture. The contents of the buret as a whole were then admitted to the cell. It was found especially important for the duplication of results that the volume of each portion admitted should be uniform. When equilibrium was attained, as shown by the constancy of the level in the manometer, a fresh portion, which in the meantime had been prepared in the buret, was run in. This process was continued until no more gas could be forced in at the maximum pressure attainable by the apparatus. The capillary from A to the cell was then sealed with a thread of mercury to prevent any possible chance of leakage, and the gas left at 0° overnight.

Inasmuch as the gaseous phase was to be analyzed and the composition of the adsorbed phase determined thereby, measurement of the adsorption isotherms had to be made during withdrawal of the gas. Such isotherms

are subject to a lag of gas leaving charcoal as compared with those determined from data obtained by measuring equilibrium pressures of gases "going in." This lag has been previously observed and is confirmed in this work. The results here obtained, however, are comparable with each other, for the lag is a relatively constant factor in them all. The question of lag will be discussed in detail in the theoretical section following.

The withdrawal of gas was made in 50cc. fractions. After measurement in the buret the gas was driven through E' to a Hempel gas buret and analyzed, correction being made for the expansion due to the mixing of gases and to the tension of aqueous vapor in the pipets. This withdrawal was continued in successive portions until the pressure was not more than 75 mm. As numerous points low in the curve were not especially inportant in this work, and as the amounts of gas which could be withdrawn by evacuation alone from this point on were extremely small, the cell was heated and all the rest of the gas was driven out. The final result gave about 14 readings for each isotherm.

The total volume of gas withdrawn agreed very closely with that admitted, the average variation being about 2 cc. in 750 cc. The same can be said of the component gases measured "going in" and analyzed "coming out."

The carbon dioxide was to all intents pure, and no difficulty was experienced in accounting for all the gas introduced; the deviations in the nitrous oxide were almost exactly equal to the nitrogen contained in the original gas (1-1.5%). Practically all of this impurity was found in the first fraction withdrawn.

As a result of this standardization of the manipulation, a surprisingly close duplication of results was obtained, both with the gases unmixed and with each of the mixtures studied, a condition not always reached in studies of adsorption by charcoal. This duplication was true of the total amount adsorbed, of the general shape of the curves, and of the amounts of the individual gases adsorbed from mixtures and their adsorption curves. In the case of each curve, duplicates were obtained in which the variation was not more than 0.5%, a smaller difference than could be shown in any plotting of the curve on an ordinary scale.

As the nitrous oxide was slightly impure, an individual run was made to see whether increased purity changed the shape of the isotherm. It has been stated above that practically all of the impurity remained unadsorbed and was removed in the first portion of the gas withdrawn, the succeeding portions analyzing over 99.7%. For this reason an isotherm run was started in the usual way, with 99% nitrous oxide from the cylinder. When the maximum pressure was reached, the system was left for four hours; then 100 cc. of gas was withdrawn and replaced by fresh nitrous oxide, thus raising the purity of all the gas in the system to 99.8%. After

the mixture had stood overnight the isotherm was determined in the usual manner. Its deviation from the isotherms previously produced without this special care was negligible. The two were identical below 2200 mm, and the variation at the highest pressure was only 1%.

Experimental Data

Table I gives the essential data for the individual adsorptions of carbon dioxide and nitrous oxide unmixed. The figures show the volume of each gas in cc. adsorbed per gram of charcoal at the pressures stated.

Discussion

From the data given above it seems possible to deduce the total amount of any mixture of carbon dioxide and nitrous oxide adsorbed by charcoal, if the isotherms of the independent adsorption of the individual gases are known. The formula

$$V_{\text{mixt}} = \frac{V_{\text{N2O}} a_1 + V_{\text{CO2}} a_2}{100}$$

in which $V_{\text{N}_2\text{O}}$ and V_{CO_2} represent the volumes of those gases separately adsorbed at the total pressure of the mixture, and a_1 and a_2 stand for the

percentages of the respective gases in the mixture, holds within reasonable limits, as shown in Table V.

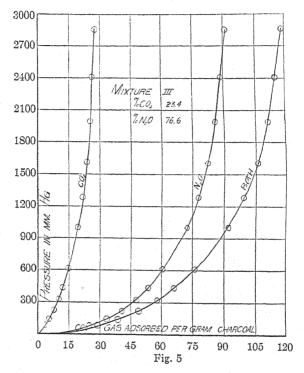

Table V

Volume of Mixture Adsorbed, Calculated from Separate Adsorption Curves,

Compared with Values Experimentally Determined

Pressure Mm.	"50–50 r Calc.	nixt." Obt.	"75-25 Calc.	mixt.'' Obt.	"25-75 r Calc.	nixt." Obt.

200	44.1	43.7	41.7	41.4	46.7	47.1

When we consider that under the best of conditions the amount of gas adsorbed by a given specimen of charcoal varies several cubic centimeters in duplicate determinations, this agreement seems remarkably close. It should be said, however, that the relative nearness to each other of the

isotherms of the two gases under consideration is particularly favorable to the application of the above formula. It might not work so well with other pairs of gases.

On the other hand, there seems to be no possibility of calculating the volume of each of the component gases adsorbed in the charcoal from the total volume of the gaseous mixture. In other words the ratio of the amounts of the two gases adsorbed varies with the pressure, whether we are dealing with them as separately in contact with the charcoal, or whether they are mixed. This fact is shown by the data given in Table VI. Col. 1 gives the pressure, Col. 2 the ratio N_2O/CO_2 in independent adsorption, Cols. 3, 4 and 5 similar ratios (the volume of each gas being multiplied by the percentage of the other in the mixture) for the three mixtures studied. It will be seen that at the lower pressures there is a continually increasing proportion of nitrous oxide adsorbed.

This point has been touched upon, in connection with other gases, by a number of other investigators. Bergter, working at pressures of not over 10 mm. with mixtures of nitrogen and oxygen, concluded that while the relationship in which the two gases are adsorbed depends very considerably upon the pressure, under conditions with which he worked oxygen is adsorbed 30 to 40 times as much as nitrogen. He also came to the curious decision that the presence of adsorbed nitrogen more than doubles the capacity of charcoal to take up oxygen. Lemon and Blodgett, working with the same gases at low pressures and at the temperature of liquid air, believe, on the contrary, that there is a nearly linear relation between the logarithm of the equilibrium pressure and the percentage of oxygen in the mixture; and that gases are not adsorbed "independently"—that the presence of one gas reduces the capacity of the charcoal to take up another. Miss Homfray, as a result of a series of single determinations of mixtures of carbon monoxide and nitrogen at pressures up to one atmosphere and at -79°, comes to the conclusion that the relative volumes of these gases adsorbed under the conditions stated is constant within an error of 2%. She made, however, no determination of a complete isotherm for any mixture, nor did she analyze the unadsorbed gases, but based her deductions on the fact that the total volume adsorbed was what it should be to satisfy a formula similar to that given above. Her conclusion, therefore, while probably valid for the total adsorption of the mixture, cannot be considered as indicating anything quantitatively definite as to the adsorption of the individual gases of the mixture.

Molecular Volumes and Adsorption

Recently suggestions have been made that a proportionality exists between degree of adsorption and the molecular volumes of the adsorbed gases. Thus Wilson, 11 using the data of Lemon and Blodgett, calls attention to the fact that in their work the ratio of moles of nitrogen adsorbed

11 Wilson, Phys. Rev., 16, 8 (1920).

to moles of oxygen is very nearly 1 to 1.3, which is the inverse ratio to their molecular volumes. Lamb and Coolidge, ¹² in researches on the adsorption of the vapors of carbon tetrachloride, ether, methyl alcohol, etc., find that a similar relationship holds. They further point out that the figures of Titoff¹³ on the adsorption of ammonia and carbon dioxide (as single gases) permit a similar conclusion. It is to be noted, however, that the pressure points at which this last relation was found to hold were selected, apparently by chance, at 20 mm.

It is obvious from an inspection of the figures in Table VI that in our work, either with single gases or with mixtures, such a relationship holds only within a limited pressure range. For the single gases the ratio varies from 1 at 2800 mm. to 1.256 at 200 mm. For the mixtures there is a similar but greater variation, reaching a maximum of 1.56 at 200 mm. The ratio of the molecular volumes of carbon dioxide and nitrous oxide is 1 to 1.025. ¹⁴ It may then be stated that, within the experimental error, the gases herein studied are adsorbed inversely as their molecular volumes at pressures ranging from 1800–2800 mm. only; and that, below this, the lower the pressure, so far as the results of this investigation can be brought to bear upon the problem, the greater the divergence from this rule. It should be noted, however, that the apparatus used in this investigation was not adapted for the determination of equilibrium points at very low pressures, and such values are not given.

As all comparisons between adsorption and molecular volumes have been made at low pressures, except those discussed in this paper, it is of interest to apply the method to previously obtained isotherms of gases over as wide a pressure range as possible, and thereby to determine whether these ratios vary as they seem to do in the present work. The comparison must, of course, be made upon the basis of data obtained from the isotherms of single gases, as mixtures have not been studied. Ammonia and carbon dioxide have been investigated through a wider pressure range than other gases: at pressures up to one atmosphere by Titoff, and at higher points by one of us.

Table VII

Ratio of Adsorption: CO₂/NH₂, at Various Pressures

¹⁴ Cailletet and Mathias, Compt. rend., 102, 1202 (1886).

The results of the comparison are given in Table VII; temperature 0°. The ratio of the molecular volumes is 1.81. Apparently, then, at 0° for very low pressures with these gases, the inverse proportionality of the adsorption to the molecular volume holds; at higher pressures the deviation increases, reaching a maximum at 100 mm. From that point, as far as these results go, it decreases. Extrapolation of Richardson's results indicate that at a pressure of 3.5–4 atmospheres the adsorption of carbon dioxide and ammonia again approaches a ratio which is inversely proportional to the molecular volumes, as it was found to be in the case of carbon dioxide and nitrous oxide in the present work.

Replaceability of One Gas by Another

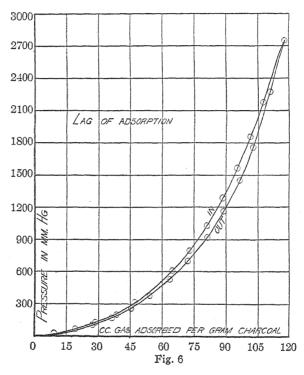

In all the experiments described above, the gases were mixed before being admitted to the charcoal. It seemed worth while to compare the result thus obtained with that gained by adding one gas (nitrous oxide) to the other, already adsorbed by the charcoal. After a certain time interval the unadsorbed gas was withdrawn and analyzed, and the composition of the gaseous phase was determined. This was compared with the composition of the gaseous phase obtained from a mixture of the same composition, admitted to the charcoal subsequent to mixing, and showing approximately the same pressure (data obtained in the course of the work previously described). The experiment was then repeated at longer time intervals until the general course of the reaction could be determined. The findings are given in percentages of unadsorbed gas: the upper value (gases mixed before adsorption) being, of course, the limit to which the others should approach.

Pressure Mm.	Time Hrs.	%N2O	%C02
1403.5		21.1	78.9
1488.9	3	47.3	52.7
1428.0	18	35.6	64.4
1400.8	39	33.9	66.1

These figures indicate that although replacement goes on rapidly at first, it proceeds at a much slower rate when about half the gas that one would expect to be replaced has been thus driven out. The speed of the action then becomes so small that it is doubtful whether an equilibrium close to that obtained with the previously mixed gases would ever be reached.

Lag

As all measurements in these determinations were made on gas withdrawn from the charcoal, they are subject to the lag of gas thus leaving, compared with the amounts entering at the same pressure. A study of the exact effect of this lag seemed desirable. It was found to be sufficiently uniform, both with the separate gases and with the mixtures, so that the results as obtained could be considered as strictly comparable. The two isotherms of carbon dioxide "going in" and "coming out" are given in Fig. 6. It will be seen that the lag reaches a maximum of about 5% at pressures from 1000 to 1600 mm., and decreases continuously toward either pressure extreme.

Summary

- 1. The adsorption isotherms of carbon dioxide and nitrous oxide independently, and in mixtures of the approximate proportions 50% CO₂–50% N₂O, 75% CO₂–25% N₂O, and 25% CO₂–75% N₂O have been determined at 0°, and through pressure ranges up to 2800 mm.
- 2. At each reference point of the three isotherms of the mixtures the amounts of the carbon dioxide and nitrous oxide adsorbed have been determined by analysis.
- 3. The total amount of the mixture adsorbed can be calculated from the independent adsorption isotherms of the individual gases.
- 4. The ratio of the degree of adsorption of the two gases varies with the pressure. Only at the highest pressure is it found to be in inverse ratio to the molecular volumes of the adsorbed substances in the liquid form.

Calculations from other work make it probable that a similar ratio holds at very low pressures.

- 5. It was shown that a gas admitted to another already adsorbed by charcoal replaces it rapidly at first, then with increasing slowness, and that replacement never goes so far as to give an amount of the second gas adsorbed equal to that which would be adsorbed from a mixture of the same composition mixed before being admitted to the charcoal.
- 6. A considerable lag in the adsorption isotherm obtained from carbon dioxide leaving charcoal compared with that obtained when the gas was entering it was detected; the lag amounted at its maximum to 5%.
- 7. The problem of the analysis of mixtures of carbon dioxide and nitrous oxide was satisfactorily worked out.

THE SOLUBILITY OF POTASSIUM PERCHLORATE IN SALT SOLUTIONS AND THE CORRESPONDING ACTIVITY RELATIONS

By Richard M. Bozorth Received September 22, 1923

Introduction

Activity values may be derived, as is well known, from the solubilities of salts in solutions of other salts through the following considerations. In any solution saturated at a definite temperature with a uni-univalent salt such as AB the product of the activities $a_{\rm A} \times a_{\rm B}$ of the ion constituents A and B has a constant value whatever other salts may be in the solution. Expressing the concentration of the ion constituents by c with appropriate subscripts and putting the activity coefficient $\alpha = a/c$, we may write for any such solution

$$c_A \alpha_A c_B \alpha_B = a \text{ constant, or } \frac{\alpha_A \alpha_B}{\alpha_{A0} \alpha_{B0}} = \frac{c_{A0} c_{B0}}{c_A c_B}$$

where the subscripts zero refer to the solution in pure water. Hence from solubility data the change can be determined of the activity-coefficient product with the nature and concentration of an added salt, or with the total concentration of the solution.

The purpose of the work described in this paper was to determine to what extent the activity-coefficient product for potassium perchlorate is dependent on the nature of the ions added to the solution. The ions for which the effect has been determined are: K⁺, Na⁺, Ba⁺⁺, Cl⁻, NO₃⁻, ClO₄⁻, SO₄⁻⁻, the added salts producing these ions being KCl, KNO₃, K₂SO₄, NaCl, NaNO₃, NaClO₄, Na₂SO₄, BaCl₂, and Ba(NO₃)₂. The total

concentrations of the saturated solutions were carried as high as 0.7–0.8 N. This work was carried out at the suggestion and with the advice of Professor A. A. Noyes, to whom I wish to express my appreciation. It was assisted financially by a grant made to him from the Carnegie Institution of Washington.

Method of Determining the Solubility

Solubilities were determined at 25°, following the method previously used by Noyes and Boggs.¹ Potassium perchlorate was recrystallized until no test for chloride ion or chlorate ion was obtained, one recrystallization being usually sufficient. Other salts were of good commercial "analyzed" quality once recrystallized, with the result that in salts other than chlorides no chloride could be detected. The salt contents of the solutions were determined by evaporating a weighed portion on a steam-bath and drying the residue to constant weight at 200°. After the solutions were saturated with potassium perchlorate, they were filtered within the thermostat, and the total salt in them determined by evaporating and weighing. Knowing the amount of salt associated with a given amount of water in each salt solution, the amount of perchlorate in the saturated solution was determined by the difference.

Saturation was approached from both the under- and over-saturated sides in the case of about half the solutions; but as no systematic difference could in any case be detected, the other determinations were made without regarding the method employed.

The Solubility Data

The results of the solubility determinations are given in Table I. The salt contents are all expressed in equivalents of salt per 1000 g. of water. The values at the foot of each section of the table are means of the (usually) four separately determined values above them.

of water. The last column of each half of the table contains the activity-coefficient product, $\alpha_{\rm A}\alpha_{\rm B}/\alpha_{\rm A_0}\alpha_{\rm B_0}$, calculated from the inverse solubility-product ratio, $c_{\rm A_0}c_{\rm B_0}/c_{\rm A}c_{\rm B}$, in accordance with the principles described in the Introduction of this article.

Discussion of the Results

The logarithm of the activity-coefficient product is plotted against the logarithm of the total salt content in Fig. 1. The striking fact shown by the graphs is that each added ion has a specific effect independent of the other ion with which it is associated. Thus potassium ion has a much

greater effect than sodium or barium ion in reducing the activity-coefficient product of potassium perchlorate, and the sodium ion has an only slightly greater effect than barium ion, these statements being true whether these ions are present with chloride, nitrate, or sulfate ion (in the cases of potassium and sodium ion). Similarly, chloride ion always exerts a much smaller effect than nitrate or sulfate ion, while the last two ions have nearly the same influence.

These effects are clearly brought out also by the values shown in Table III of the activity-coefficient product interpolated for a total concentration of $0.5\ N$. The differences in the product caused by replacing one ion by another are seen to have a definite value no matter what ion of opposite

sign is present with the two ions to be compared; for example, the difference in the activity-coefficient product caused by replacing potassium by sodium is about 0.09 whether the potassium and sodium are associated with chloride, nitrate or sulfate.

Table III

Values of the Activity-Coefficient Product at a Total Concentration of 0.5

				Norma	L,			
Salt added	Activity product	Differ- ence	Salt added	Activity product	Differ- ence	Salt added	Activity product	Differ- ence
KC1	0.705		KNO_3	0.600		K_2SO_4	0.597	
		0.093	0.090				0.089	
NaC1	.798		NaNO:	. 690		Na_2SO_4	.686	
		.023			.027			
$BaCl_2$.821		Ba(NO	$(3)_2$. 717				
KC1	.705	;	NaCl	.798		$BaCl_2$.821	
		.105			.108			. 104
KNO_3	.600	l garage	NaNO:	.690		Ba(NO	$_3)_2$.717	
		.003			.004			
K_2SO_4	. 597		Na_2SO_4	.686				

These results show that the effects of the different ions are specific and additive at the fairly large concentrations $(0.25\text{--}0.75\ N)$ here prevailing. These specific effects are so marked as to hide any influence of the valence of the added ion; thus at the same normality barium ion has not far from the same effect as sodium ion, but a much less effect than potassium ion, and sulfate ion has nearly the same effect as nitrate ion, but a much greater effect than chloride ion.

Summary

The solubilities of potassium perchlorate have been determined in 0.1, 0.3, and 0.6 N solutions of the salts KCl, KNO₃, K₂SO₄, NaCl, NaNO₃, NaClO₄, Na₂SO₄, BaCl₂ and Ba(NO₃)₂. The individual effects of the separate ions on the activity-coefficient product of the potassium and chlorate ions have been compared, and at the concentrations involved (0.25–0.75 N) have been found to be markedly specific and additive.

SURFACE ENERGY OF SEVERAL SALTS

By Merle L. Dundon¹ Received September 28, 1923

Introduction.—In a previous article² the method of calculating surface energy from the increased solubility of fine particles was considered, and a value for the surface energy of gypsum calculated from new data. In the present work an attempt has been made to measure the change in solubility due to change in size of particles for several other substances. The best

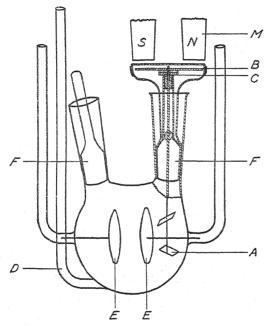

Fig. 1.—Conductivity cell

opportunity for such an investigation occurs with suby stances of small solubility. in which case equilibrium comes about with such slowness that it can be followed by frequent conductivity measurements. Such solubility equilibria must, however, be easily obtained, and continued hydrolysis other decomposition in solution must not occur. With many of the substances considered, such as lead sulfate, mercurous chloride magnesium fluoride, some interfering factor of this sort soon developed, which made it impossible to obtain data of use in this study. those substances which gave

positive results and which are mentioned in this paper, lead fluoride, because of its many favorable properties, was investigated most extensively.

Experimental Method.—Fine powders have been obtained by hand-grinding in an agate mortar, with a mechanically operated mortar and pestle, or with a steel ball mill. Ordinarily, the powder was used directly, and the size of the smallest particles present in large numbers was the value recorded. Attempts were made to sort the particles into different sizes and to calculate the sizes by settling in water or alcohol, making use of Stokes' law. This method failed to yield satisfactory results because of the coalescence of the settling particles into clumps and also, no doubt, because of the adsorption effect at the surface of the small particles.³ In the case of lead fluoride, how-

³ Williams, Trans. Faraday Soc., 18, 53 (1922).

ever, an air elutriation method was devised, of such a sort that the powder was carried upward through a long glass tower, and very uniformly sized particles, 0.3μ , were obtained, with no particles larger than 0.5μ . Consequently, a good deal of confidence may be placed in the results for lead fluoride.

Measurement of the size of particles was made with a calibrated scale in the eyepiece of a microscope having a magnification of 1800 diameters. Several conductivity cells were used, including the Kohlrausch type, some large flasks with suspended electrodes, and one cell especially designed for this work. This cell is shown in Fig. 1. The platinum paddle-wheel stirrer A can be operated by a magnet M outside the cell. The stirrer shaft of platinum was set into a brass plug at the top and had a drop of glass fused around it lower down to keep it in position. The steel bar B was fastened to the brass plug with a small screw which passed through the washers C. All metal parts other than the platinum were gold-plated. The glass cap above the bar is held in position by a rubber band. F is the ground-glass stopper.

The data for calculating concentrations from conductivity values, such as temperature coefficients, equivalent conductivities, etc., have been obtained in most cases from the work of Kohlrausch. A water correction has been applied to all conductivity values given.

Lead Fluoride

No crystallographic data concerning lead fluoride could be found in the literature and no crystals larger than a few microns were made. However, it was determined that they belong to the orthorhombic system and have an average refractive index of 1.83 and a hardness of about 2.

Hydrolysis of the Solution.—Saturated lead fluoride solutions are distinctly acid, having a Sörensen value of about 1, and the acidity changes very little over a considerable range of dilution. Kohlrausch⁵ found that in the variation of equivalent conductivity with dilution at 18° hydrolysis was not indicated, and his results on this point have been widely quoted. It was found in this investigation at 25° that, although a given solution remained constant, considerable hydrolysis took place on dilution, giving a value for the equivalent conductivity at infinite dilution which is much too high.

Calculation of Concentrations.—A carefully prepared saturated solution had a conductivity of 513×10^{-6} mhos, and gravimetric analysis showed the equivalent concentration to be 0.00555. Experimental data were then obtained from which a curve of equivalent conductivity against the cube root of the concentration was plotted. From this a second curve was plotted giving equivalent concentrations directly in terms of specific conductivity. Several gravimetric analyses of supersaturated solution prepared from fine powder checked this curve almost exactly.

Method of Obtaining Equilibrium.—A saturated solution was pipetted into the cell from a stock solution, powder added and the cell shaken

⁴ Thanks are due to Professor W. J. McCaughey of the Department of Mineralogy, Ohio State University, for assistance in making these determinations.

⁵ Kohlrausch, Z. physik. Chem., 64, 134 (1908).

thoroughly, after which the maximum conductivity was reached in from two to ten minutes. The conductivity then gradually decreased for several days. Sometimes, in order to hasten the final equilibrium, the solution was carefully filtered and coarse crystals were added. In some cases also, a few drops of conductivity water were added to the supersaturated solution in order to hasten the final equilibrium. When too much water was added the conductivity again increased to approach the normal equilibrium. This change served as a means of determining whether a solution of conductivity higher than normal at the end of a test was still supersaturated, or whether the higher conductivity was due to impurities.

 $^{^{\}circ}$ A water correction not greater than 2 \times 10 $^{-\circ}$ was applied to the saturated solutions to bring them to the value determined gravimetrically as correct (0.00555 gramequivalents per liter).

In Table I are tabulated the most reliable data obtained on the increase in solubility of lead fluoride. In the first three experiments, the fine powder was added to the saturated solution and the solution kept until the conductivity had again decreased to a point where it was constant. In Expts. 4 and 5 the solution was filtered as soon as possible after the addition of the fine powder and the concentration also determined by gravimetric analysis. In No. 6 the powder was added directly to water and the solution observed until it had returned nearly to the saturated value. In Expt. 7 a supersaturated solution was prepared by heating a solution to boiling with an excess of crystals and filtering the liquid into the cell. Fine

^b When the supersaturated solution in contact with crystals failed to return to the conductivity value corresponding to a normal saturated solution, the presence of impurities was indicated. On this assumption, therefore, in columns marked "Corr. for return" a correction equal to the difference between the beginning and end solutions has been subtracted from the high value.

Five minutes after adding powder.

powder was then added and the conductivity found to increase slightly and then decrease to a value considerably below the starting point. This showed that the solution was not sufficiently concentrated to be in equilibrium with the finest particles present. The final conductivity when the solution became constant indicates considerable contamination, due either to increased hydrolysis at the higher temperature or to impurities acquired during the boiling and filtering. The increase calculated after applying corrections is high, but the powder was an unusually fine sample.

No. 8 is very similar to No. 7, except that the original solution was less concentrated and the maximum concentration reached was lower. In the case of No. 9, the original solution was more concentrated than a solution in equilibrium with the powder. This, therefore, sets an upper limit on the maximum increase in solubility for a powder of the size used. In a similar experiment not tabulated, an increased concentration of 20% was found to be much too high and a very rapid decrease occurred upon addition of the powder. It is interesting to note that the concentration reached five minutes after addition of the powder is approximately the same in No. 8 as in No. 9 although the point was approached from different directions.

Nine per cent. has been taken as the value representing the increased solubility of lead fluoride powder 0.3μ in diameter. Working with a saturated solution of lead fluoride in 95% alcohol, an effect of about the same magnitude was found.

Lead Todide

Lead iodide gave a very small increased solubility effect. It is soft and flaky and is difficult to grind into a fine powder, even with the aid of fine quartz. The smallest particles were about 0.4μ in diameter. In two minutes an increase in concentration of about 2% was obtained.

Strontium Sulfate

Small particles added to solutions of strontium sulfate failed to disappear and allow the solution to return to the normal equilibrium. This may be due partially to a very slow rate of solution in this case, but similar difficulties occurred and are discussed in greater detail in connection with barium sulfate. While an initial increase as high as 25% was obtained for particles $0.3\,\mu$ in diameter, there was never more than a 2% return from the maximum.

Silver Chromate

A precipitate composed of good orthorhombic crystals from 10 to 50μ in length was made by mixing very dilute hot solutions of silver nitrate and potassium chromate. The crystals were easily ground. The average size of the small particles was considered to be 0.3μ . The solutions were constant in cells with bare electrodes, but the conductivity of a saturated solution decreased when put into a cell with platinized electrodes. After

adding 0.35 g. of powder to 500 cc. of solution and stirring the mixture with pure air, 24 hours was required to reach a maximum conductivity. The resulting solution when pipetted into another cell and stirred in contact with coarse crystals by means of a platinum paddle-wheel stirrer showed a decrease in conductivity for three days. After this time a slight but gradual increase set in, probably due to contamination of some kind. Two experiments at 26° agreed very closely, the fine powder causing an increase in equivalent concentration from 0.192×10^{-6} to 0.218×10^{-6} , or 13.5%, and the return in three days was 7%. In view of possible contamination or decomposition affecting the conductivity, 10% seems to be the most reasonable estimate of the real increase.

Calcium Fluoride

In one experiment pure mineral fluor spar was used. For the others, c.p. calcium fluoride was ground fine and digested several times with water until only coarse crystals remained. In some cases the powder was all added at once, and in other cases at intervals until no more effect was noticed on further addition. The time required for the powder to produce a maximum conductivity was usually from three to five minutes, but in one case was 24 minutes. This was followed by a decrease for about five days with all the solid added still present. With four experiments the increases were 24%, 19%, 32% and 29%, and the subsequent decreases were 10.5%, 15%, 12% and 17%. Considering the possible influence of impurities on the conductivity and the slow digestion back to the normal value the real increase in concentration for a given powder cannot be more than the original increase nor less than the return. Therefore, 18% is taken as the value for use in calculating the surface energy. The size of the finest powder was 0.2μ – 0.3μ with some larger particles.

Barium Sulfate

The method used for strontium sulfate was not successful with barium sulfate, because of the failure of the fine particles in the solution to disappear or grow to a larger size in any reasonable length of time.

Instead, a highly supersaturated solution (at 30°) in which the barium sulfate did not precipitate was prepared by mixing approximately equivalent quantities of very dilute sulfuric acid and barium hydroxide. The conductivity of this solution was constant at 21.4×10^{-6} . Fine barium sulfate, 0.2μ in size, was added, whereupon the conductivity fell in five hours to 16×10^{-6} where it remained practically constant for three days. Some of the clear solution was then pipetted into another cell and large crystals, 2μ – 20μ , were added. The change was slow, but in three days the conductivity fell to 12.9×10^{-6} . If it is assumed that the correction for water and impurities, such as excess acid or base, is 9.3×10^{-6} (the difference between the last value and the normal value for a saturated solution).

the solubility of particles $0.2\,\mu$ in diameter is 90% greater than that of the larger crystals.

Failure of Particles to Disappear or Grow

Attention has just been called to the failure of small barium sulfate particles to dissolve. This was also true of all the other substances studied, although to a more limited extent. Whenever, upon addition of a finely powdered substance to its saturated solution, the conductivity had gone up and then had slowly returned to its initial normal value, the expectation was that all of the smaller particles had dissolved and crystallized from the supersaturated solution onto the large crystals present. But this is not what happened. Particles were left in the solution at the end, which were just as small apparently as those present at the beginning, and these small particles, even though in intimate contact with large crystals, showed no tendency to dissolve. Frequently, large crystals formed in solution without seeding, starting with small uniform particles, as in the case of lead fluoride; but here, too, at the end of the process many small ones remained.

These facts indicate either that a large part of the increased solubility is due to particles in the powder too small to be seen and measured, or soon after entering the solution the increased solubility of the small particles is decreased by some adsorption effect such as the acquisition of a charge. The latter explanation seems more in harmony with the facts.

This effect was shown in a striking manner by the behavior of barium sulfate particles. Several very fine precipitates were made from barium hydroxide and sulfuric acid. One sample was made 0.1 N acid, one alkaline to the same degree, and the others were neutral. The precipitates were not retained by a filter, did not settle for several hours, and under the microscope most of the particles appeared to be 0.2μ – 0.3μ or less in size. After standing for three months and being frequently shaken, they could be filtered, but under the microscope most particles still appeared to be as small as 0.3μ and certainly few, if any, were larger than 0.5μ . One of the samples was then boiled under a reflux condenser for a week with no visible change even when seeded with large crystals. The particles were found to have a negative charge as they migrated very definitely in a U-tube under a potential of 125 volts.

When 10 cc. of concd. hydrochloric acid was added to 100 cc. of the suspension and the boiling continued, a marked change took place. After a few hours particles several microns in length appeared, and after four days all particles were at least $1.5\,\mu$ and some were as large as $3\,\mu \times 10\,\mu$.

If the growth of large particles at the expense of the smaller ones is a surface-energy effect, then the hydrochloric acid must act either to increase the surface energy at the solid-liquid interface, or else to remove those interfering factors which previously had prevented the normal surface energy from exerting its influence.

If we consider only the Ostwald-Freundlich equation, the calculated increase in solubility as particles become very small is so large that it seems improbable, and we are led to believe that some other factor enters to prevent actual attainment of the solubility predicted. W. C. M. Lewis⁶ has proposed an expression, also independently developed and extended by Knapp, which is based on the assumption that an electrical charge present on the surface of a small particle would decrease the solubility of such a particle. The curve plotted by Knapp from his equation shows that after a certain decrease in size a maximum solubility is reached, and for smaller particles the solubility is again diminished as we pass into the region of colloids. It seems probable that such a charge, by decreasing the surface energy and thus diminishing the increased solubility, may bring about a condition of equilibrium and prevent the further growth of particles at any size between those of a stable colloid and coarse crystals. If this is true, then the increased solubility for a definite size of particle would depend largely on conditions in the solution, and surface-energy calculations based on a solubility increase may be in error from this cause.

Calculation of Surface Energy.—By substituting the data giving the solubility of different sized particles in the equation⁸

$$\sigma = \frac{i RTr \rho \ln \frac{Sr}{S}}{2M} \tag{1}$$

it is possible to calculate the surface energy at the solid-liquid interface. It is evident, however, that all data obtained so far, including those of the

⁸ For a discussion of this equation see the previous paper, Ref. 2.

present paper, are liable to so many errors that such calculations cannot be made with any great degree of exactness. In fact, besides the charge effect, the unknown shape of the fine particles, the errors in measurement of their size, the different rate of solution of different crystal faces, and the influence of crystal habit on the immediate growth of the particles, are certainly factors which interfere very seriously with the applicability of an equation based on the assumption that particles are spherical with uniform surfaces. However, the values for surface energy in Table II are the most nearly correct that can be obtained from data available at this time.

It will be seen that there is a rough proportionality between surface energy and hardness, as might be expected. It is further evident from Equation 1 that, other things being equal, the surface energy should vary directly as the density and inversely as the molecular weight; in other words, the surface energy should vary inversely as the molecular volume. This general relation is indicated by the table. However, the solubility increase varies greatly with different substances, and it is evident that such a relation can hold only for substances of the same general type.

This inverse relation between surface energy and molecular volume is approximately true for the fused lithium, sodium, potassium, rubidium and cesium compounds of fluorine, chlorine, bromine and iodine, and their nitrates and sulfates. Of all these alkali salts lithium fluoride has the smallest molecular volume and consequently the largest surface energy. At 1270° it is 201 ergs per sq. cm., at 1000° it is 237, and at 870° it is 250, making an extrapolated value of about 350 at 25°, for the supercooled liquid. By substituting 350 for σ in Equation 1 the calculated increase in solubility for particles of lithium fluoride 0.3μ in diameter would only be about 1%. As a matter of fact, it was not possible with the methods employed in this investigation to detect an effect with lithium fluoride as great as 0.5%, showing the very slightly increased solubility of fine powders with substances of small molecular weight.

This work was made possible through a National Research Fellowship. The author also wishes to thank Dr. Edward Mack, Jr., for his suggestions and encouragement.

Summary

- 1. A value for the surface energy has been calculated from the increased solubility of small particles for lead fluoride, lead iodide, silver chromate, strontium sulfate, barium sulfate and calcium fluoride.
- 2. It has been shown that a rough proportionality exists between surface energy and hardness, and the inverse proportion between surface energy and molecular volume, predicted by the Ostwald-Freundlich equation, has been indicated.
- ⁹ F. M. Jaeger, Verslag Akad. Wetenschappen Amsterdam, 17, 555 (1914); Z. anorg. allgem. Chem., 101, 1 (1917).

3. It has been observed that fine particles may have their solubility diminished by an electrical charge or adsorption effect on the surface.

THE PREPARATION OF DIPHENYL

By Carroll H. Lowe and C. James Received February 14, 1923

After the publication of a paper¹ in which the preparation of diphenyl was given, one of the present authors received several letters stating that the process failed to give good results. Since these statements were so contrary to those given in the original article, it seemed advisable to make a reinvestigation. A careful study of the faults of the first method revealed the fact that there were two striking difficulties which could be overcome only by bringing much sounder mechanical principles into play.

The first troublesome factor was the incessant short circuiting due to the expansion and sagging of the Nichrome ribbon filament, when heated. The second element of trouble was that due to superheating at the points where the filament came in contact with the means of support.

Description of the New Apparatus

As in the old, the new apparatus consisted of a 12-liter Pyrex flask, supported by a tripod. In the neck of the flask a tightly fitting stopper was inserted, through which a hole had been bored for the delivery tube of the inverted condenser. The latter was retained in a perpendicular position by means of an iron stand and clamp. In addition to the hole for the delivery tube, three symmetrically placed, very small holes were bored, through which passed the rods of the internal mechanism. Their purpose was to serve as threaded axes of the necessary binding posts for the essential electrical connections.

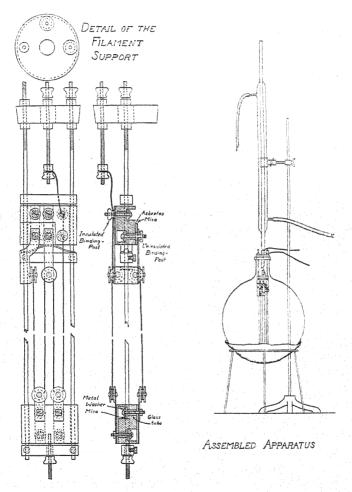

As has been previously mentioned, the problem was mainly one concerning an adequate filament support. After considerable experimentation, a type that was highly satisfactory was devised, all the faults of the old process being completely eliminated. The main supports consisted of two parallel steel rods, threaded on the ends that passed through the cork. These were securely retained in position by three steel cross-braces, two of which were held firmly in place by set screws.

Two larger blocks of steel were grooved on the edges and placed between the rods. This allowed the former to slide up and down, easily, as far as the cross-braces would permit. Between the middle cross-brace and upper block a powerful, arched strap spring of steel was inserted.

¹ This Journal, 39, 933 (1917).

Through the center of the lower cross-brace, a 6mm. hole was bored. This allowed free passage of the threaded steel wire which was screwed into the lower block, parallel to the main supporting rods.

On the opposite end of the threaded wire was an adjusting screw, the purpose of which was to secure the desired tension on the filament before

use. Once the filament was in position, it became an easy matter to tighten it, and the resulting tension would cause a depression of the arched spring. Upon passage of the electric current through the filament the expansion which took place was taken up by the tendency of the depressed spring to assume its former position, thus keeping the filament taut at all times. This removed the possibility of short circuiting and eliminated one of the main difficulties of the old apparatus.

Instead of using a 4-stranded filament as formerly recommended, one of S strands was used, thereby doubling the heating surface. This filament did not reach a higher point than the base of the neck of the flask.

On each of the movable blocks were brass, flanged discs over which the filament passed from strand to strand. This method of holding the filament in place did away with the troublesome superheating and prevented any danger of breaking due to sharp cornered hooks.

One of the special features in this apparatus is the method of insulating the flanged discs against contact with the blocks themselves. The details of this, however, are much better given by the accompanying drawings than could be attempted in words. Whatever specifications are lacking above will be found clearly indicated in these drawings.

Precautions

In attempting to run this new process a few precautions are absolutely necessary.

To begin with, the operator must never lose sight of the fact that it is a very dangerous procedure to attempt heating the filament, to incandescence, until all of the air within the flask has been expelled. Should any oxygen be present, it will promote combustion of the benzene and a very serious explosion may result. As a measure of additional safety, it is highly advisable to install an automatic cut-off, in case the current is temporarily shut off.

Care must be taken not to over-heat the filament; it should be maintained at a yellowish-red tinge. Under the best conditions a mist forms, the benzene returning from the condenser has a yellowish color and diphenyl streams down the sides of the hot flask. Formation of carbon at different points will give a warning of over-heating. It should be remembered that no part of the filament ought to be in the liquid phase. If the bottom of the lower block just touches the surface of the liquid, sufficient heat will be transmitted through it to keep the liquid boiling.

It is highly advisable to keep the filament at an even temperature throughout the entire run, although it will not break should it be cooled a few times. It is only a matter of 5 or 10 minutes' time to replace the old with a new filament.

The mechanical parts should be cleaned often in order that the tarry residue, which is deposited all over the surfaces, may be prevented from retarding their free and easy motion. When the filament support is not in use, it should be kept immersed in a small covered container filled with benzene.

Results.—One kilogram of diphenyl has been obtained in a 24-hour run, using a current of 110 volts and 10 to 12 amperes. The amount of byproducts separated by fractional distillation is not very great.

The application of this type of apparatus for other processes, involving simple heat effect, or where the filament is covered with catalytic material such as oxides, etc., is now under investigation.

Summary

- 1. A filament support has been described which eliminates all previous difficulties in the preparation of diphenyl, such as local heating and short circuiting due to expansion and sagging.
- 2. Very good yields of diphenyl can be obtained from benzene by maintaining the Nichrome filament at a yellowish-red heat.
- 3. The benzene used was commercially pure and not anhydrous. The addition of more water did not hasten the reaction.

DURHAM, NEW HAMPSHIRE

[Contribution from the Soils Laboratory, Agricultural Experiment Station, University of Missouri]

THE NATURE OF THE ACIDITY OF THE COLLOIDAL CLAY OF ACID SOILS

By Richard Bradfield

RECEIVED MAY 11, 1923

The problem of soil acidity has probably been investigated more than any other one soil problem, but in spite of the vast amount of work that has been done there is still considerable doubt as to its real nature.

Fisher¹ in his excellent résumé of the subject concludes: "It cannot be said that the enormous amount of work done has either solved the practical problem or clarified our ideas as to what exactly soil acidity means."

The earlier chemists believed with Sprengel² that soil acidity was due to the accumulation of complex insoluble organic acids. Recent work by Odén,³ using electrochemical methods, has established the validity of Sprengel's contention when applied to soils high in organic matter. Some of our most acid soils, however, are very low in organic matter and their acidity must be due to some other cause. If aqueous extracts of most acid soils are boiled to expel the carbon dioxide they will not as a rule be sufficiently acid to redden litmus paper even though the moist soil itself may change it almost immediately. This and similar observations led to some doubt as to the existence of real acids in soils and to the idea of "negative acidity." The conception of "negative acidity" had its origin in the work of Van Bemmelen who found that certain colloids and soils exhibited a preferential absorption for bases when treated with neutral salts, leaving the solution acid. This idea was developed into the selective adsorption theory of soil acidity by Cameron, Parker, Harris and others. 4 Ramman discarded the expression

"acid soils" using instead "absorptively unsaturated soils." Salter and Morgan⁵ in a recent study of the effect of the soil-water ratio on the Sörensen value of acid soils, found that the relationship was logarithmic and could be expressed by the usual absorption isotherm. They concluded that their data "discredit any theory of soil acidity which assumes that the acid reaction is due to highly insoluble acids, organic or inorganic which must under conditions of equilibrium form a saturated solution and give a constant Ph."

A great number of the recent workers on soil acidity believe, nevertheless, in the existence of highly complex insoluble alumino-silicic acids. This theory proposed by Loew in 1913 has been substantiated by the work of Ashley, Mellor and Clark⁶ on the constitution of pure clays, and by Truog⁷ who worked with agricultural soils. Soil chemists are practically unanimous in the opinion that the condition called "soil acidity" is due to a removal of the soluble bases by prolonged leaching. Since soils are composed of complex minerals, which are salts of strong bases and weak acids, it is to be expected that they would hydrolyze slowly, producing soluble bases which would be leached away by the rains and the insoluble acid residue would remain in situ to accumulate as the weathering proceeded. MacIntire⁸ points out that the degree of acidity of a soil is closely correlated with its degree of hydration.

The principal arguments against the true acid theory are (1) that equivalent quantities of different bases are not taken up by soils, (2) that the titration curves of soils by bases show no breaks corresponding to neutral points but are almost linear. Truog' found however that, if experimental conditions were adjusted so as to keep side reactions at a minimum, equivalent quantities of bases were taken up by soils. The absence of breaks in the titration curves may be due, as will be shown later, to the fact that such titrations are usually made by adding increments of the standard base to a definite quantity of the acid soil. This is quite contrary to the teachings of physical chemistry. If a sharp end-point is desired the weak acid should be added to the strong base.

A survey of the literature on soil acidity shows that the following points are very well established regardless of the nature of the underlying causes.

- 1. Natural soils vary in Sörensen (PH) value from about 3.5 to 9.5.
- 2. Aqueous extracts of acid soils when freed from carbon dioxide are usually acid-free.
- 3. Extracts of acid soils made with neutral salt solutions show a higher Sörensen value than the soil, and also considerable titrable acidity.
- 4. Titration curves, made by adding increments of bases to a fixed weight of soil and determining the corresponding Sörensen values show no definite breaks to indicate end-points, but are almost linear.
- 5. The slope of the curve varies widely with soil type. It is usually inversely proportional to the content of colloidal material. In other words the buffer action of a soil is some direct function of its colloid content.

Principles Underlying the Present Investigation

Soils are complex systems with particles ranging from a few millimeters in diameter down to molecular dimensions. The rate at which a

 - · 8 MacIntire, J. Am. Soc. Agron., 13, 157 (1921).

chemical reaction proceeds increases with a decrease in the size of the reacting particles. It is to be expected then that the more finely divided colloidal material in soils would reach an equilibrium much more quickly than the non-colloidal fraction. The situation is probably complicated still more in soils by the fact that the colloidal fraction forms a coating over the coarser particles which would tend to protect them. Because of this complexity of the soil system it would seem logical to use a physically homogeneous fraction for studies of the nature of the acidity. Since the buffer action of soils is closely correlated with their colloid content, the colloid fraction would seem to be the one best adapted for such studies. It has the additional advantages of having a high specific surface and of being accurately measurable by means of ordinary pipets and burets, which greatly facilitates titrations.

The end-point in the titration of colored solutions can readily be determined by conductivity measurements. The conductivity is at a minimum at the neutral point in the case of the titration of a strong base by a strong acid, and it makes little difference in that case whether the acid is added to the base or the reverse. If, however, a strong base is being neutralized by a weak acid the conductivity curve shows no increase after the neutral point is reached, but remains practically constant. If the process is reversed, and the strong base added to the weak acid, which is the method usually followed in soil investigations as pointed out by Findlay, "The minimum will not be sharp owing to the fact that the change in conductance is not due so much to the disappearance of the fast-moving hydrion (which is present in comparatively small concentration) as to the replacement of the un-ionized acid molecules by the ions of the salt formed."

A similar situation exists in making a titration curve by means of the hydrogen electrode. In order to obtain distinct breaks at the end-points of the titration the amount of buffering substances should always be kept at a minimum. This can be done by titrating the strong base with the weak soil acid. In the work of Knight, Spurway, and Stevenson, in increments of the standard alkali solution were added to fixed quantities of soils. Under such conditions a maximum amount of either the weak soil acid or its salt is always present, exerting so great a buffer action that these investigators find an almost linear relationship between the amounts of base added and the increase in Sörensen value produced.

In this investigation standard solutions of sodium hydroxide and calcium hydroxide were titrated with the colloidal material from four acid

soils and the end-points located by both conductivity and hydrogen-ion concentration measurements.¹¹

Experimental Part

The colloidal clay was extracted from the heavy sub-soils of the Marion, Cherokee, Putnam and Robertsville silt loams, each of which is very acid and very low in organic matter, by the method developed in this Laboratory. The solutions used contained 1 g. of oven-dried material per 100 cc. except in the case of the Robertsville, which contained 2 g.

Preliminary trials indicated that the basic solutions should have a normality of the order of $0.01\ N$. Ten cc. of $0.01\ N$ base was placed in a $100{\rm cc}$, graduated flask by means of a pipet and the desired quantity of the 1% colloidal clay solution added. Enough neutral distilled water was added to bring the volume up to $100\ {\rm cc}$. (except in the case of the additions of $100\ {\rm cc}$. or over). After the solutions were thoroughly mixed, they were poured into $100{\rm cc}$. florence flasks which were kept stoppered to minimize contamination by carbon dioxide. About $15\ {\rm minutes}$ after mixing, a portion of the mixture was used for a hydrogen-ion determination. These determinations were made with a standard potentiometer, using the saturated potassium chloride calomel electrode and a modification of the Hildebrand type of hydrogen electrode. The temperature varied only slightly from $25\ {\rm ^\circ}$.

The conductivity measurements were made by the usual bridge method, using a Washburn Type B cell, a microphone hummer as a source of alternating current and a tunable telephone receiver to indicate the point of balance. The resistance was kept constant at 9999 ohms and the results are reported as bridge readings. The potentiometer was used as a bridge. The bridge wire was 1100 units long. The temperature was maintained at 25° \pm .02 by a small thermostat.

Experimental Results.—The 1% stock solutions of the colloidal clays gave the conductivities and Sörensen values shown in Table I.

TABLE I

CONDUCTIVITY	and Sörensen	VALUES OF	1% COLLOIDA	L CLAY	Solutions
Soil			E.m.f.	$P_{ m H}$	Bridge reading
Putnam			0.498	4.30	935
Cherokee			520	4.65	990
Marion			506	4.42	1007

The rate of reaction between the colloidal solutions and the bases was studied by mixing the two in the desired proportions as usual, then determining the conductivity at frequent intervals. Equilibrium was attained almost instantly. Bridge readings taken as soon after mixing as possible were almost identical with those taken after standing overnight.

¹¹ THIS JOURNAL, 45, 1245 (1923).

The titration curves for the Putnam and Cherokee clays obtained by both the conductivity and hydrogen electrode methods are given in Fig. 1. The curve for the Marion clay was almost identical in type with the Putnam and is for that reason omitted. About twice the usual quantity of base was used in the curve for the Robertsville clay (III) in order to place

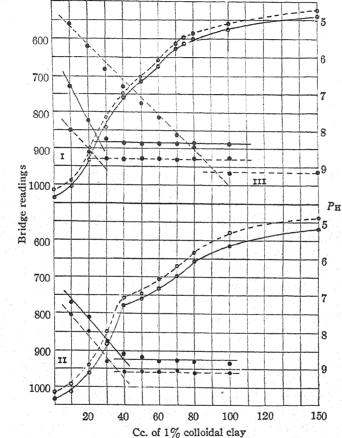

Fig. 1.—Titration curves of Putnam clay (I), Cherokee clay (II), and Robertsville clay (III). Circles represent hydrogen-electrode curves; dots, conductivity curves. Broken lines denote that Ca(OH)₂ was the base used; continuous lines, NaOH

more points on the slanting portions of the curve. (A 2% solution of the Robertsville clay was used and the results plotted on the 1% basis.) The conductivity curves are all of the type commonly obtained in the titration of a strong base by a weak acid. As the strong base is neutralized and replaced by the comparatively insoluble salt of the alumino-silicic acid, the conductivity decreases linearly. After all of the base has been neutralized, the conductivity becomes constant and the addition of an excess

of the weak colloidal acid has no effect. If we were dealing with an adsorption of the type expressed by Freundlich's isotherm instead of a neutralization, we should expect the curve to continue to drop in a logarithmic fashion until the value of the colloidal clay was approached. The curves obtained with calcium hydroxide approach this point, as would be expected from the low solubility of the calcium silicates and from the differences in the mobilities of the calcium and hydrogen ions but the minimum conductivity obtained with sodium hydroxide was in every case considerably higher than that of untreated clays; increasing the amount of clay almost four times after this minimum had been obtained failed to reduce the conductivity further. This would seem to indicate that in this case either we have an ordinary neutralization with the formation of the sodium salt of the acid which is more soluble than the acid itself, or from the adsorption point of view the colloidal clay regardless of the amount present is unable to adsorb the sodium beyond a certain critical concentration. Adsorptions are usually characterized by the lack of stoichiometric relations between the quantities of different bases taken up. In the conductivity curves of all the clays studied the two linear portions of the curves intersect at a point (the end-point) which corresponds to approximately the same amount of acid regardless of the nature of the base, which would seem to be rather conclusive evidence of the stoichiometric character of the reaction.

The curves obtained with the hydrogen electrode are also of the type commonly obtained in the neutralization of a strong base by a weak acid. The flatter portion of the curves in the most alkaline region is not as pronounced as in most titration curves, probably due largely to the great dilution of the standard alkali used (0.001 N after dilution). There is in each case a slight change in the slope of the curves at about PH 7. This break is especially marked in the case of the Cherokee and indicates that there may be at least two distinct dissociation constants involved. The curves gradually flatten as an excess of the colloidal acids is added and approach the Sörensen value of the pure acids. The curves for sodium hydroxide follow those for calcium hydroxide very closely, confirming the conductivity curves, but show always slightly more alkalinity. This is doubtless due partly to differences in the solubility and hydrolysis of the salts formed and partly to a slight difference in the concentration of the basic solutions used. The sodium hydroxide solution was slightly over 0.01 N (0.0105) and the calcium hydroxide solution was not quite 0.01 N (0.0099). This difference when calculated to equivalents of the colloidal acids makes a difference of about 1.8 cc. of the 1% solutions.

The end-points of the titration obtained by the two methods (the intersection of the linear portions in the case of the conductivity curves and the midpoint of the steep portion of the curve in the case of the PH curves) lie as close together as could be expected with a weak acid of this type.

About 37 cc. of 1% Cherokee, 27 cc. of 1% Putnam, and 37 cc. of 1% Marion soil were required to neutralize 10 cc. of the 0.01~N bases. This gives the 1% solutions of the acids about the following normalities, Cherokee 0.0027, Putnam 0.0037 and Marion 0.0027.

Discussion of Results

The chief objections to the chemical theory of soil acidity are (1) no one has ever been able to isolate an undeniable acid from a soil in quantities commensurate with the soil's "sourness;" (2) acid soils do not absorb bases in equivalent quantities; (3) titration curves made by titrating a comparatively large mass of soil with a base are practically linear, showing no break such as is characteristic of true neutralizations.

The results obtained in this investigation tend to show that the colloidal material of an acid soil is itself an acid which ionizes to produce a definite Sörensen value and which shows a definite titrable acidity or normality on titration with strong bases. The fact that the acid is colloidal explains why it is not found in colloid-free aqueous extracts. Soils investigators have as a rule been expecting to obtain a negative ion of the soil acid which would be of the same dimensions as the ordinary crystalloid ion. This could hardly be expected if we consider the great complexity of the minerals which are found in soils. It would seem much more logical to expect the anion of the soil acid to be very large and complex, even reaching colloidal dimensions.

It has long been known that clay particles when suspended in water and placed in an electrical field migrate to the anode. Recent measurements in this Laboratory show that the velocity of migration of the colloidal particles is of the same order of magnitude as that of the average slow moving ion of crystalloids. This shows that the particles have an electric charge of the same order of magnitude as that of the crystalloid ion. This charge has commonly been ascribed to the preferential adsorption of hydroxyl ions by the colloidal particle. If the excess of hydrogen ions in the colloidal clays studied is due to the ionizing of the colloidal particles themselves, as this work indicates, then an equal negative charge must remain on the residual colloidal particle. These charged colloidal particles would be in reality very large complex negative ions, as the cataphoresis experiments indicate. This view is in harmony with the findings of Loeb, Pauli, Michaelis, Sörensen and others in their investigations of colloidal protein solutions and with the work of McBain on colloidal electrolytes.

The results obtained by Salter and Morgan⁵ which are discussed above would be expected if they were dealing with a colloidal acid. Their argument in favor of the adsorption theory is based on their belief that

¹² Russell, "Soil Conditions and Plant Growth," Longmans, Green and Co., London, 1921, p. 110.

they were dealing in all the soil-water ratios studied, with a saturated solution. This fundamental assumption is not necessarily true. Their belief that they were dealing with a saturated solution was apparently based upon the fact that there always remained a certain amount of the solid phase undissolved. A considerable portion of most soils is made up of rather coarse particles of minerals such as quartz which are very inactive. The amount of colloidal material is in most cases comparatively small. so small as to make it seem highly improbable that the solution was saturated even with a ratio of 1 part of soil to 1 part of water. Their curves began to flatten, however, in the most concentrated mixtures, which indicates that they were probably approaching a concentration in which the Sörensen value would become constant. Any weak acid will yield a logarithmic curve for certain concentrations when its hydrogen-ion concentration is plotted against its concentration. The curve becomes linear only when the acid is completely dissociated at infinite dilution. The curve of Salter and Morgan becomes practically linear at the point corresponding to 100 g. of soils to 1000 cc. of water which indicates that they have reached a concentration corresponding to infinite dilution at that ratio. Instead of discrediting a colloidal acid theory of soil acidity, their results would seem to be exactly what would be expected from such a theory.

The second objection to the true acid theory of soil acidity is that equivalent amounts of bases are not removed. As pointed out above such results have usually been attained when a relatively large ratio of soil to reacting base was used. Such conditions favor complex side reactions in which the solubilities of the resulting salts play a role. Truog has shown that if a small sample of soil is treated with a large excess of the base or salt, conditions favoring the direct action and unfavorable to the side reactions, approximately equivalent quantities of bases are taken up. In this investigation the same end was accomplished by adding small increments of the colloidal acid to a definite quantity of strong bases. The titration curves for calcium and sodium hydroxides in each case lie so close together that if we take into consideration the differences in the solubilities of the alumino-silicates which are indicated in the conductivity curves, there can be little doubt that equivalent quantities of the two bases are neutralized by the colloidal acid.

The third objection, that soil titration curves do not exhibit definite breaks, has been shown to be unfounded provided that the strong base is titrated with the weak soil acid. With the reverse procedure, which is usually followed in soil investigations, an excess of the weak acids and their salts, the substances responsible for the high buffer action are present from the start and tend to obscure the breaks normally expected. The end-points found by the conductivity method are as sharp as those commonly obtained with weak acids.

The curves obtained by the hydrogen-electrode method are also of the type usually obtained with very weak acids. There are no sharp breaks, but the slope changes gradually, showing the least buffer action between PH 9.5 and 7. At the latter point there is a slight flattening of the curve with all clays studied. This flattening is more marked with the Cherokee soil than with any of the others (Fig. 1, II). It seems to be as pronounced as that observed in the titration of certain weak crystalloidal acids such as phthalic acid¹³ and would seem to be evidence that at least a dibasic acid was involved. It would be difficult to account for such a change by the adsorption theory but it is exactly what would be expected if we were dealing with a true neutralization of a base by a weak polybasic acid.

There yet remains the possibility that the acidity neutralized is due to acids other than alumino-silicic. As pointed out above, the colloids used in this study were extracted from the sub-soils of four soils very low in organic matter. They were likewise very low in phosphate and sulfate. The percentages of these substances were so low and the quantity of colloidal acid used so small as to render it inconceivable that the acidity found was due either to organic acids or to traces of the more common strong inorganic acids.

In spite of the strong acidity of the soil colloids and of the fact that the colloid content of soils is much higher than is commonly believed, as has been shown by the recent work of Moore, Fry and Middleton¹⁴ and confirmed in this Laboratory, it is not believed that such acidity accounts for all the acidity of sour soils. The exteriors of the larger non-colloidal particles of such soils have doubtless lost considerable of their bases. The work of Brown and Johnson, Truog¹⁵ and others indicates that the interior of such particles when freshly exposed to the solvent action of water after thorough grinding may contain enough soluble bases to render the solution alkaline in reaction. Such particles are probably responsible for most of the so-called latent acidity, since the results obtained in this investigation indicate that the reaction of the colloidal material is very rapid.

Additional evidence in favor of the true acid nature of acid colloidal clays is found in the studies previously reported, ¹⁶ in which it was found that the concentration of potassium ions required for complete flocculation of the acid clay increased about 10-fold when the Sörensen value was raised from 6.5 to 8.5, and then became constant, indicating that after a sufficient concentration of hydroxyl ions to neutralize the acid has been added further increases (almost a thousand-fold) are without effect.

Other studies on the variation of the hydrogen-ion concentration of the acid clays upon dilution gave curves apparently identical in type with those obtained with weak acids such as acetic acid.¹⁷

Summary

- 1. Solutions of calcium and sodium hydroxides were titrated with 1% solutions of four subsoil colloidal clays. The end-points found by both the conductivity method and the hydrogen electrode were fairly definite and the curves were of the type usually obtained in titrating a strong base with a weak acid.
- 2. The same amounts of the colloidal acids were required to neutralize equivalent quantities of the two bases.
- 3. Definite breaks were found in the conductivity curves, indicating the neutralization of definite acids which in 1% solutions had concentrations ranging from 0.0027 to 0.0037 N.
- 4. The reaction between acid colloidal clays and strong bases seems to be an ordinary neutralization. Recourse to the adsorption theory seems unnecessary.

STUDIES ON ENZYME ACTION. THE RELATIONSHIP BETWEEN THE CHEMICAL STRUCTURE OF CERTAIN COMPOUNDS AND THEIR EFFECT UPON THE ACTIVITY OF UREASE

By Elbert W. Rockwood and William J. Husa Received June 29, 1923

Various organic compounds have been reported as influencing the activity of urease.¹ Lövgren² gives a rather full review of the general properties of urease and includes a bibliography containing over 200 references. From his review of the literature Lövgren concludes that all the promoters³ are weak acids of amphoteric electrolytes, and that their accelerating influence lies in their checking of the PH increase.

It was one of the purposes of this investigation to determine whether the promoter action reported by several investigators could be entirely explained on the basis of $P_{\rm H}$ changes, or whether there was a further effect independent of this one. Provided such an effect was found; it was believed desirable to look for a possible relationship between the chemical structure of the compounds and their action on urease, and to investigate the mechanism of the action. It was hoped that such a study would throw some light on the nature of enzyme action, and at the same time would contribute to our knowledge of promoters.³

Materials Used

A solid urease preparation was obtained from jack-bean meal by the method of Van Slyke and Cullen.⁴ Urea was purified by recrystallization from ethanol. The compounds tested were obtained from reputable manufacturers, or from reliable research chemists, to whom we are indebted for compounds unobtainable elsewhere.

Experimental Procedure

Experiments were carried out with 0.1 M urea, the optimum PH of 7.5 being maintained by use of a phosphate buffer. For the controls, 5 cc. of distilled water was introduced into a 200cc. Erlenmever flask, 25 cc. of M phosphate solution (50 volumes of M dipotassium and 9 volumes of M monopotassium orthophosphate) was added, then 15 cc. of a 2% solution of urea and 5 cc. of a 0.1% solution of enzyme, making a total volume of 50 cc. In the other flasks, the compound to be tested was first placed, in amount sufficient to make 50 cc. of a 0.001 M solution. Water was added. and then sufficient alkali or acid to make the aqueous solution neutral to phenolphthalein, so that it could be more readily controlled by the buffer, the given volume of dil. potassium hydroxide or sulfuric acid solution replacing part of the 5 cc. of water. The other solutions, including the buffer, were then added as in the controls. Since light is known to hasten the decomposition of urease,2 the flasks were placed in a dark cupboard for the reaction period of approximately two hours. The variation in temperature during this time was less than 1°, and during the whole course of the work the temperature ranged from 21-28°. For analysis, a 10cc. portion of the reaction mixture was pipetted into a bottle containing 35 cc. of a saturated solution of potassium carbonate and 25 cc. of distilled water. When the action of the enzyme was thus stopped there was still an ample excess of substrate, 75 to 90% remaining unchanged. The ammonia was aerated into a mixture of 25 cc. of 0.1 N sulfuric acid and 50 cc. of distilled water and the excess acid determined by titration with 0.1 N potassium hydroxide solution, using methyl red as indicator. The time of aeration was from $3^{1}/2$ to 7 hours, depending on the room temperature.

4 Van Slyke and Cullen, J. Biol. Chem., 19, 211 (1914).

The results of Lövgren² were used in choosing the concentrations of urea and of the phosphates. According to his results for $0.1\,M$ urea and $0.5\,M$ phosphates, the formation of ammonia corresponding to $2\,$ cc. of $0.1\,N$ ammonia for each $10\,$ cc. of the mixture caused a change of $0.1\,$ Sörensen unit. Since the amount of promoter in $10\,$ cc. of the mixture corresponds to only $0.1\,$ cc. of a $0.1\,M$ solution, the difference between the control and the solution containing the added substance would thus be of the order of a few hundredths of a Sörensen unit. Thus, by neutralizing the compound to be tested and employing the $0.5\,M$ buffer, the effect of the added substance on the hydrogen-ion concentration was eliminated.

Experimental Data

Table I contains a summary of the results obtained with various classes of compounds. Table II summarizes the data on each compound tested. The activity of the enzyme in the presence of the added substances is expressed on the basis of the control taken as 100.

Table I
Summarized Results Given by Different Classes of Compounds

Class Classification	No. of compounds tested	Av. of series
I Mono-amino-monocarboxylic acids

Discussion

Relationship between Promoter Effect and Changes in Hydrogen-Ion Concentration.—The effects of the various added substances reported in the tables above cannot be explained on the basis of changes in hydrogenion concentration, contrary to the claims of Lövgren.² That the promoter action studied here is independent of such effects is assured by the fact that the substances tested were employed in 0.001 M concentration, neutralized and used in the presence of a 0.5 M phosphate buffer mixture.

Relationship between Chemical Structure and Promoter Effect

Are Certain Elements Essential?—In formulating a relationship between the composition or chemical structure of the compounds and their effect upon the activity of urease it may be seen at once that the action cannot be ascribed to the presence of a single element such as nitrogen, carbon, hydrogen or oxygen, nor to the mere presence of a number of elements in a compound. True, all the promoters found in our work contain ni-

b For this we are indebted to Mr. E. P. Clark.

trogen, carbon, hydrogen and oxygen, but many other compounds containing these same elements exerted no favorable action.

Effect of the Amino Group Alone.—By a further analysis of the data in terms of groups it is seen that all the promoters contain an amino or substituted amino group. That the -NH₂ group alone is not responsible for the greater action is evidenced by the results obtained with four simple amines. As shown in Tables I and II, no promoter effect was observed, the average yield of ammonia being 98% of that from the control.

Effect of the Carboxylic Group Alone.—Jacoby and Umeda^{1f} reported that no effect on the activity of urease was observed on addition of neutralized glutaric acid, COOHCH₂CH₂COOH. Our own experiments with benzoic acid, o-, m-, and p-acetylaminobenzoic acids and guanidine acetic acid also show that when care is taken to exclude changes in hydrogen-ion concentration, the carboxyl group alone has no promoter effect.

Effect of Amino and Carboxyl Groups.—Every compound which acted as a promoter contained both the amino and carboxyl groups. However, a number of compounds, both aliphatic and aromatic, containing these two groups exerted no favorable effect.

Effect of Relative Position of These Groups.—The results in Table II indicate that α -amino acids are decided promoters, β -amino acids have in some cases a slight effect, in other cases no effect, while the only γ -amino acid available had no favorable influence. In the aromatic series, the isomeric aminobenzoic acids were tested. While only the *ortho* compound showed a slight favorable effect, it seemed significant that the order was ortho > meta > para. The results with both aliphatic and aromatic compounds (although less marked with the latter) containing an amino and a carboxyl group indicate that the promoter action is a function of the distance between these groups, the stimulating effect increasing with decreasing proximity of the two groups.

Effect of Substituted Amino and Carboxyl Groups.—The methyl ester of histidine gave the same results as histidine itself, a result which indicates that esterification of the carboxyl group in a promoter does not decrease the favorable effect. Hippuric acid was a marked promoter; this result shows that the benzoyl group may replace one hydrogen of the amino group without decreasing the promoter action.

Effect of a Second Carboxyl Group and its Position.—From the data in Tables I and II it appears that the second carboxyl group slightly increases the promoter effect. In one experiment in which the two compounds were compared directly against the same control, the result for aspartic acid was 133, and that for glutamic acid 129. Since in glutamic acid the second carboxyl is separated from the amino group by one more carbon atom than in aspartic acid, it is possible that the promoter effect may depend somewhat on the proximity of the second carboxyl group.

Effect of a Second Amino Group.—A second amino group was found to increase the promoter effect. The results with arginine (guanidine- α -aminovaleric acid) averaged 153, a value which is considerably higher than the average for α -mono-amino-monocarboxylic acids.

Effect of Second Amino and Carboxyl Groups in the Same Compound.—From the results obtained with cystine it appears that the second amino group does not increase the promoter effect if there are two carboxyl groups, while a second carboxyl group does not increase the promoter effect if there are two amino groups in the compound. There is a possibility, however, that the two thio groups of cystine may influence the promoter effect.

Effect of a Heterocycle Containing Nitrogen.—Tables I and II indicate that α -amino acids having in addition a nitrogenous heterocycle give, on the average, a somewhat greater promoter effect than simple α -amino acids.

Effect of Length of Chain.—There is some indication that in aliphatic α -amino acids the promoter effect decreases with lengthening of the carbon chain. Thus the average value obtained for CH₂(NH₂)COOH was 127; for CH₃CH(NH₂)COOH, 121; and for (CH₃)₂CHCH₂CH(NH₂)COOH, 118.

Effect of Optical Isomers.—Jacoby and Umeda^{1f} working with urease without, however, eliminating changes in hydrogen-ion concentration observed no difference in action between dl-alanine and d-alanine, or between dl-glutamic acid and d-glutamic acid. In our experiments, in which effects of hydrogen-ion concentration played no part, the promoter effects of dl-alanine and d-alanine were also found to be practically equal.

Compounds Having No Promoter Action

Effect of Ammonium Chloride.—Armstrong and Horton^{1a} and other investigators have reported a favorable action of ammonium chloride on urease. In our work, changes in hydrogen-ion concentration being eliminated and correction made for the ammonia from the ammonium chloride, no such greater action has been found. Thus the favorable effect of ammonium chloride reported by others is not the specific effect demonstrated in this investigation.

Effect of Guanidine Derivatives.—Because of the apparent favorable influence of the guanidine group in arginine, other guanidine derivatives were tested. Guanidine sulfate, guanidine acetic acid, creatine and creatinine gave no promoter effect. To cover the field an amino-naphthol, an oxime and various other compounds were tried (see Table II), but no promoter effect was observed.

Effect on Activity of Enzyme as a Test for the α -Amino Group

From the results of our work it appears that the effect of a compound on the activity of urease might furnish valuable presumptive evidence as to the presence of an amino group in the α -position to a carboxyl group. An opportunity to apply this method presented itself in connection with the isolation of a new amino acid from casein by Mueller.⁵ He reported that the empirical formula of the compound was $C_5H_{11}O_2NS$, and that tests were obtained showing the presence of an amino group and a carboxyl group. The results obtained with this substance showed a depressing effect on the activity of the enzyme, the average being 84% of the controls. It would appear that this new sulfur-containing amino acid is not an α -amino-monocarboxylic acid of the cystine type.

Importance of Protein Associated with Enzymes

Enzymes seem to be of a protein nature or to occur associated with protein. When the protein is removed from an enzyme solution by coagulation with heat or other means the activity is lost. For this reason it is often stated that enzymes are proteins, or something more complex containing protein.

Van Slyke and Cullen⁴ found that their soya urease preparation contained a few per cent. of ash, the organic matter being about ²/₃ protein and ¹/₃ carbohydrate. Since three days' digestion with trypsin or papain did not markedly injure the activity of the enzyme it seemed to them unlikely that the urease was of a protein nature.

Jacoby and Umeda, If working with soya urease without controlling the hydrogen-ion concentration found the activity of the enzyme to be increased by glycyltryptophan, Witte's peptone and casein. Our experiments indicated that Witte's peptone exerts a promoter action comparable to that shown by α -amino acids.

Jacoby and Sugga⁷ reported that soya urease was not appreciably injured by dialysis, or by treatment with trypsin or papayotin. When the urease preparation was first treated with papayotin and then dialyzed, they observed a marked diminution in the activity of the urease.

Their results may be explained as follows. It has been shown that α -amino acids, peptones and proteins serve as promoters of the catalytic action of the urease. It would, therefore, be reasonable to expect a fall in activity of the enzyme preparation when the compounds containing α -amino groups are removed. Proteins being, as a rule, non-diffusible, dialysis alone might not appreciably affect the action of the urease. Further, since our work has shown that α -amino acids and peptones are marked promoters, it is evident that the breaking down of the proteins into peptones and amino acids by treatment with trypsin or papayotin should likewise not change the rate of fermentation. But if the urease preparation is dialyzed after treatment with papayotin, the protein having been changed

⁵ Mueller, J. Biol. Chem., 55, xv (1923).

⁶ Kindly furnished by Dr. Mueller.

⁷ Jacoby and Sugga, Biochem. Z., 69, 116 (1915).

into diffusible amino acids which would be removed by the dialysis, a diminution in activity of the urease should be expected. The results of Jacoby and Sugga⁷ may thus be explained on the basis that the protein part of an enzyme preparation, by its promoter action, accounts for part of the activity of the enzyme.

The Mechanism of the Promoter Effect

Various explanations have been given⁸ of the manner in which the activity of enzymes is increased by added substances. Sherman and Naylor⁹ conclude that the influence of amino acids on amylases "may be attributed either to a direct 'activating' effect dependent upon the structural nature of these substances as α -amino acids, or to conservation of the enzyme by retarding its hydrolysis."

In dealing with urease one must also consider whether an added substance such as an amino acid might not interact with the enzyme to form ammonia. Likewise, the ureolytic power of bacteria from the air must be remembered, although solutions of purified urea do not offer a medium favorable to microörganisms which can readily hydrolyze the urea in urine. To learn whether there were any secondary effects, the following experiment was carried out. The concentrations in the reacting mixture were 0.1 M urea, 0.01% urease preparation and 0.05% dl- α -alanine. No buffer was used and the ammonia could thus be determined by direct titration with alkali after the reaction had been stopped by the addition of standard sulfuric acid solution. To allow maximum opportunity for possible bacterial action and other effects the solutions described below were allowed to act for two days instead of for the usual time of two hours.

	TAB	E III	
Substances present besides distilled water	Cc. of 0.1069 I NH ₃ generated 10cc. sample	in present besides	Cc. of 0.1069 N NH; generated in 10cc, sample
Enzyme	0.0	Urea + α-alanine	(neutr.) 0.1
Urea	0.0	Urea + enzyme	3.1
α-Alanine (neutralized)	0.0	Urea + enzyme	+ α-alanine
Enzyme $+ \alpha$ -alanine (neutr.)	0.0	(neutr.)	

These results indicate that no ammonia is formed by hydrolytic or bacterial decomposition of urea, urease or α -alanine alone, or by interaction of the enzyme with the amino acid. Urea in the presence of α -alanine undergoes a small but measurable change, which may be due to a slight catalytic activity of the amino acid, or to bacterial action due to improvement of the medium for growth of microörganisms. In any case the effect could

⁸ Ford, J. Soc. Chem. Ind., 23, 414 (1904). Donath, Hofmeister's Beitr., 10, 390 (1907). Ref. 1i. Sherman and Walker, This Journal, 43, 2461 (1921). ⁹ Sherman and Naylor, This Journal, 44, 2957 (1922).

scarcely be observed in a two-hour reaction period and it is by no means an important part of the promoter effect reported in this paper. A similar experiment with histidine, in the presence of the phosphate buffer, confirmed the conclusion that there is only a negligible amount of ammonia formed by the action of the amino acid alone on urea. The α -alanine does not catalyze the hydrolysis of urea to an important extent but does increase the catalytic activity of the urease, and we are thus dealing with an undoubted promoter action.³

It is well known that aqueous solutions of enzymes lose their activity on standing at room temperature and that at higher temperatures this decomposition proceeds more rapidly. Our experiments showed that glycine in $0.001\,M$ concentration protected urease from heat destruction at $75\,^\circ$ to a marked degree. Experiments were then carried out to determine whether this protective action was great enough at room temperature to account for the promoter action reported in this paper. In one set of experiments the decomposition on standing in the absence of substrate of an aqueous solution of the enzyme alone and with an amino acid present was studied. In the other set of experiments the rate of decomposition of the enzyme with and without amino acid was determined in the presence of the substrate, that is, while the enzyme was functioning as a catalyst.

Decomposition in Absence of Substrate.—An experiment was conducted using the same procedure and the same concentrations as in the tests of the effect of added substances. As a control the activity of a freshly prepared enzyme solution was determined by a two-hour digestion after standing for 0 hours and 15 hours, respectively. The activity was also determined with amino acid present during digestion only, as well as with amino acid present during both periods. The results in cc. of 0.0653 N ammonia were as follows.

		Table IV	
Time of standing Hours	Control	dl-α-Alanine added just before digestion	dl-α-Alanine present both before and during digestion
0	4.73	5.45	5.39
15	3.25	3.67	3.87
% Decomp. in 15 hours	31	33	30

The decomposition of urease in presence of the amino acid was from 1 to 3% less than in the control over a 15-hour period, while the promoter action of the amino acid for a two-hour digestion was 14% with an enzyme solution tested immediately after dissolving the urease and 19% with an enzyme solution which had been standing 15 hours. Thus, while a slight protective action of the amino acid has been demonstrated, most of the increase in catalytic activity of the enzyme must be attributed to a direct promoter action.

Decomposition in Presence of Substrate.—When urease is added to a

solution of urea, and the amount of ammonia formed is determined for successive one-hour intervals, it is found that less urea is hydrolyzed during the second hour than during the first hour. This apparent decrease in rate of change may be ascribed to three causes: (1) to the decrease in concentration of substrate, (2) to a retarding effect of the products formed, and (3) to decomposition of the enzyme. Instead of expressing the experimental results in terms of the amount of ammonia formed in a given time, the length of time necessary to form a given quantity of ammonia may be obtained by interpolation on a curve in which the amount of ammonia formed is plotted against time. By this procedure the decrease in concentration of the substrate and any effects of the products formed will be the same in the control and in the parallel determinations, and the extent of decomposition of the enzyme may be closely estimated by comparing the percentage increase in time required in the two cases to bring about equal increments of change in successive intervals. That is, if in one digestion the enzyme is decomposing faster than in another, more time, proportionately, will be required for bringing about the second increment of change in the first case than in the second.

Experiments were carried out with dl- α -alanine and with histidine, using the same procedure and same concentrations as were used in the tests of the effect of various added substances.

Table V Expt. 125

				to form 1st	to form 2d
	Cc. of	0.0653 N NHs formed	in	3cc. of 0.0653 N NH ₂	3cc. of 0.0653 N NH2
	1 hr.	2 hrs.	3 hrs.	Min.	Min.
Control	2.63	4.84	6.72	70	88
dl - α -Alanine added	2.83	5.12	7.18	64	81

In the control the second period required 18 minutes longer than the first, indicating on the average 26% less enzyme activity during the second period. In the presence of dl- α -alanine 17 minutes longer was required, showing a 27% decrease in rate of enzyme action during the second period. These results show that the enzyme was being decomposed as rapidly in the presence of amino acid as when no amino acid has been added. Comparing the two first periods a decrease in time from 70 to 64 minutes or 9% was obtained by the addition of dl- α -alanine. Since

Table VI Expt. 126

	Cc. of 1 hr.	0.0653 N NH ₃ 2 hrs.	formed in 3 hrs.	Time required to form 1st 2.5 cc. of 0.0653 N NH ₂ Min,	Time required to form 2d 2.5 cc. of 0.0653 N NH Min,
Control	2.25	4.13	5.85	69	82
dl - α -Alanine added	2.40	4.49	6.31	62	75

the destruction of enzyme in each case was practically the same, the promoter action cannot be explained on the basis of a prevention of destruction of the enzyme.

Thirteen minutes longer was required for the second period in each case, indicating on the average a 19% slower rate of action in the control and a 21% slower rate of action in the presence of dl- α -alanine during the second period. These results indicate that the enzyme is destroyed as rapidly while exerting its catalytic effect in the presence of dl- α -alanine as in its absence. The amino acid brought about a 10% decrease in time required for the first period (as is seen by comparing the two first periods), and this promoter action, is, therefore, due to an increased activity of the enzyme brought about by the amino acid.

The results obtained with histidine led to the same conclusion as those with dl- α -alanine. The experiments thus disprove the hypothesis that the promoter effect is due chiefly to prevention of decomposition of the enzyme. On the other hand, the results support the view that the promoters directly facilitate the interaction of the enzyme with the substrate.

Summary

- 1. It has been found that certain compounds exert a promoter effect on the catalytic activity of the urease of the jack bean. It was also shown that some compounds have an inhibitory action. These effects are independent of changes in hydrogen-ion concentration and do not result from the attainment of a concentration of electrolytes more favorable or unfavorable to the action of the enzyme.
- 2. The promoter effect is related to the presence of amino and carboxyl groups in the same compound, since each promoter contained both these groups, while compounds containing only one of them were not promoters.
- 3. The results with both aliphatic and aromatic compounds containing an amino and a carboxyl group indicate that the promoter action is a function of the distance between these groups, the stimulating effect increasing with decrease in their proximity. All α -amino acids tested are marked promoters, β -amino acids have a slight promoter action, and γ -amino acids have no effect. The isomeric aminobenzoic acids, in order of decreasing promoter effect are: ortho > meta > para.
- 4. In α -amino acids, replacement of one hydrogen of the amino group by benzoyl, or esterification of the carboxyl group does not diminish the promoter action.
- 5. A second carboxyl group in an α -amino acid appears to increase the promoter effect slightly.
- 6. A second amino-group in an α -amino acid was found to increase the promoter action.

- 7. A second amino group in a compound already containing one amino and two carboxyl groups, or a second carboxyl group in a compound already containing one carboxyl and two amino groups does not appear to increase the promoter effect.
- 8. α -Amino acids with a nitrogenous heterocycle give, on the average, a somewhat greater promoter effect than simple α -amino acids.
- 9. There is some indication that in aliphatic α -amino acids the promoter effect decreases with lengthening carbon chain.
 - 10. In α -amino acids, optical isomers do not differ in promoter effect.
- 11. Ammonium chloride has no promoter action when changes in hydrogen-ion concentration are eliminated and correction is made for the ammonia it contains. Thus the favorable effect of ammonium chloride reported by others^{1a} is not the specific effect demonstrated in this investigation.
- 12. From the results of our work it appears that the effect of a compound on the activity of urease may furnish valuable presumptive evidence as to the presence of an amino group in the α position to carboxyl.
- 13. The experiments which show the promoter action of α -aminocarboxylic acids and of peptones indicate that the protein part of enzyme preparations is an important factor in the action of the enzyme because its promoter action accounts for part of the activity of the enzyme.
- 14. The experiments tend to disprove the hypothesis that the promoter effect is due chiefly to prevention of decomposition of the enzyme. On the other hand, the results support the view that the promoters directly facilitate the interaction of the enzyme with the substrate.

A NEW METHOD FOR THE DETERMINATION OF ACETIC ACID IN ACETIC ANHYDRIDE

By James H. Walton and Lloyd L. Withrow Received July 23, 1923

Acetic anhydride has become so important a reagent in organic synthesis, that a rapid and accurate method for determining its chief impurity, acetic acid, is very desirable. In a recent investigation by E. R. Schierz¹ and the senior author of this paper a method for determining this substance was indicated.

When formic acid is added to acetic anhydride, it is broken up quantitatively according to the equation $HCOOH = H_2O + CO$. At ordinary temperatures the reaction proceeds so slowly that it is practically unmeasurable. It was found by Schierz that this reaction is catalyzed by

¹ Schierz, This Journal, 45, 455 (1923).

the following tertiary nitrogen bases which are listed in the order of decreasing activity: strychnine, brucine, nicotine, cocaine, pyridine, morphine, quinine.

In the presence of small amounts of acetic acid the catalytic activity of certain of these compounds was greatly reduced. Since the retardation was found to be proportional to the concentration of the acetic acid it was thought that this effect could be used as the basis of a method for determining small amounts of acetic acid in acetic anhydride. It was planned to prepare pure acetic anhydride and measure the rate of decomposition in the presence of a given concentration of catalyst. The rate of decomposition in the presence of various concentrations of acetic acid could then be determined, and these data used to plot a curve showing the effect of acetic acid on the catalytic decomposition of formic acid. A solution of acetic anhydride could then be analyzed by adding the proper amounts of formic acid and catalyst, measuring the velocity of decomposition and reading on the curve the percentage of acetic acid corresponding to the velocity constant obtained.

Acetic Anhydride.—A commercial preparation labeled 97% was used for the preparation of the pure anhydride. To remove the acetic acid this material was allowed to stand in contact with thin slices of metallic sodium for several days. The mixture was then refluxed under reduced pressure for several hours and was finally distilled from a mixture of metallic sodium and sodium acetate. The latter substance aids in the retention of any free acetic acid that might still be present. On distilling the acetic anhydride the first portion that came over was greenish. This was discarded. The latter portion distilled at a constant temperature. Its physical constants, stated below, compare favorably with those given by Orton and Jones: b. p., 139.3 (740 mm.); d^{26} , 1.0765; n_D^{25} , 1.3885; n_D^{31} , 1.3863. Further evidence of the purity of this anhydride is the fact that when frozen in liquid air it congealed without clouding. When anhydride of 98.7% purity was frozen, crystals of acetic acid separated at -50° . The anhydride prepared by the method described above melted at -86° .

This anhydride was tested for the presence of acetaldehyde by the method of Stepp and Frick. Approximately 0.1% was found present. Acetone was absent.

Strychnine.—Commercially pure strychnine was recrystallized from ethyl alcohol and dried at 100°.

Formic Acid.—An 85% solution was dehydrated at 50° with anhydrous oxalic acid. The solution was then cooled and the crystals of oxalic acid were filtered off. Upon distillation a very concentrated solution was obtained. This was dehydrated with boric acid and distilled, a product practically 100% pure being obtained.

Apparatus.—The velocity of decomposition of the formic acid was determined by placing the reaction mixture in a flask containing some pieces of glass rod, shaking it vigorously to avoid supersaturation, and measuring the rate of evolution of gas by collecting it over water in water-jacketed burets.⁵ The catalyst and anhydride were first placed in the flask. The formic acid was placed in a capsule held in the neck of the flask

² Orton and Jones, J. Chem. Soc., 101, 1720 (1912).

³ Stepp and Frick, Z. physik. Chem., 116, 233 (1921).

Schlesinger and Martin, This Journal, 36, 1589 (1914).

Walton, Z. physik. Chem., 47, 185 (1904).

in such a manner that it could be dropped whenever desired. The reaction takes place very slowly at room temperature, so all determinations were made at 35°. It was shown by Schierz that this reaction is monomolecular.

Results.—Table I summarizes a typical run made with the pure anhydride, formic acid and catalyst. In this experiment, as in all others made in this investigation, 25 cc. of acetic anhydride, 0.25 g. of strychnine (catalyst) and 0.07 cc. of formic acid were used in each experiment. This amount of formic acid gives about 35 cc. of carbon monoxide measured at 0° and 760 mm. In this table, T, X, A and K have their usual significance in the formula for a reaction of the first order.

TABLE I
THE DECOMPOSITION OF FORMIC ACID IN PURE ACETIC ANHYDRIDE USING STRYCHNINE
AS CATALYST

T	X	A - X		K
1.5	18	19.8	•	0.437
2	22.3	15.7		.440
2.5	25.8	12.2		.452
3	28.2	9.8		.450
3.5	29.2	8.8		.421
4	31.8	7.2		.415
5	34	4.0		.436
A = 38.00			Av.	.434

Repeated: K = 0.425 and 0.487

It will be noted that this experiment was extremely rapid, the reaction being almost 90% complete in 5 minutes. Taking this fact into consideration, the agreement of the constants is satisfactory. The acetic anhydride used in each of the experiments was purified and freshly distilled for that particular experiment. It is believed that no one of these samples contained more than a slight trace of acetic acid.

Since the acetic anhydride contains a small amount of aldehyde the influence of the presence of this substance on the rate of the reaction was investigated. When present to the extent of 5% in a sample of acetic anhydride containing a small quantity of acetic acid it changed the velocity constant from 0.320 to 0.315; the effect can consequently be neglected. Schierz showed that the rate of the reaction is not influenced by the presence of small quantities of ketones or aromatic aldehydes.

A number of experiments were carried out to determine the effect of various concentrations of acetic acid on the velocity of this reaction. Since the rate of decomposition in the presence of acetic acid is slower, more concordant results than those listed in Table I were obtained. Because of the extreme slowness of the reaction, concentrations of acetic acid greater than 5% were not used. The results of the experiments are given in Table II and are shown graphically in Fig. 1.

These results indicate that wherever the analysis of acetic anhydride for acetic acid is a part of the routine work this method will be found satisfactory. It is extremely rapid and sufficiently accurate for most purposes. For determining the presence of very small amounts of acetic acid the method can be improved by carrying out the experiment at 25°;

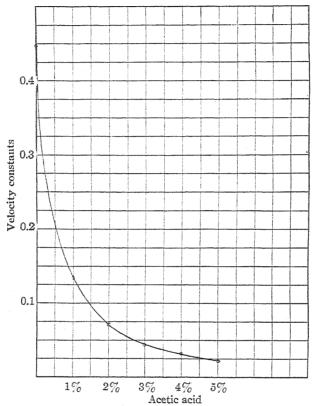

Fig. 1.—The influence of acetic acid on the catalytic decomposition of formic acid

at this temperature the reaction would be almost half as fast and the velocity could be measured more accurately. For higher concentrations of acetic acid than 5% a temperature of decomposition higher than 35°

TABLE II

THE EFFECT OF ACETIC ACID UPON THE RATE OF DECOMPOSITION OF FORMIC ACID IN

ACETIC ANHYDRIDE SOLUTION

Conen, of acid	K	$K_{ ext{dup}}$.	Kav.	K conen. acid				
0			0.447	•••				
1	0.134	0.135	0.135	0.135				
2	.0664	.0689	.677	.135				
3	.0468	.0467	.468	.140				
4	.0334	.0319	.327	.130				
5	.0236	.0238	.237	.119				

could be used or the solution diluted with enough pure acetic anhydride to bring the concentration of the acetic acid to approximately 5%.

The last column of Table II shows that when from 1 to 4% of acetic acid is present the value [Velocity constant \times concn. acetic acid] equals a constant. In other words the retardation of this reaction is directly proportional to the concentration of acetic acid. When more acetic acid is added this relationship does not hold.

Summary

- 1. A method for preparing acetic anhydride of a high degree of purity is described and certain physical properties of the anhydride have been determined
- 2. The effect of different concentrations of acetic acid upon the rate of decomposition of formic acid in acetic anhydride solution, using strychnine as a catalyst, has been determined. This forms a basis for the quantitative analysis of acetic anhydride for acetic acid when 1 to 5% of this impurity is present.

STUDIES CONCERNING THE DIRECT PREPARATION OF
ORGANOBERYLLIUM HALIDES1

By Henry Gilman Received July 31, 1923

Introduction

Much of the importance of organometallic compounds in synthetic work is confined to those compounds formed from metals of the second group of the periodic system. Zeltner,² from a study of many organometallic compounds, has called attention to two apparently general rules concerning the reactivity of such compounds which have each of the ordinary valences of the metal satisfied by an alkyl or aryl group. First, in a given group of metals having the same radicals attached to the metal, that organometallic compound with the metal of lowest atomic weight is most reactive. Second, with a given metal, that organometallic compound which has the lightest radicals is most reactive.

If these generalizations are true, it follows that one should expect an organoberyllium compound having alkyl groups of low molecular weight to be most reactive in a group which already contains several organometallic types of high reactivity. If organoberyllium halides could be prepared and if they should exhibit this reactivity, they might make pos-

¹ An abstract of a paper presented at the Intersectional Meeting of the American Chemical Society held at Urbana, Illinois, May 5, 1923.

² Zeltner, J. prakt. Chem., 77, 393 (1908).

sible a number of reactions which cannot be realized with the ordinary Grignard reagent of the general formula RMgX.

The organometallic halides or "mixed organometallic compounds," largely because of their ease of preparation, convenience in handling, and high reactivity, have displaced almost completely from synthetic work the longer known, simple organometallic compounds which have no halogen directly attached to the metal.

Simple organoberyllium compounds such as beryllium diethyl and dipropyl have long been known.³ No mention, however, is to be found in the literature of an organoberyllium halide. Several investigators have attempted to prepare such compounds directly. Grignard⁴ tried without success to bring metallic beryllium into reaction with a simple alkyl halide. Simonis⁴ tried methyl iodide, bromobenzene, and benzyl bromide in absolute ether, using iodine as a catalyst, but could get no one of the compounds to react with his beryllium. Kamm⁴ tried methyl iodide, ethyl iodide and ethyl bromide and, using freshly prepared Grignard reagent as a catalyst, likewise failed to bring about a reaction.

The following series of unsuccessful attempts was made to prepare organoberyllium halides.

Experimental Part

The metallic beryllium used was obtained from five different sources. Two samples came from foreign manufacturers, a third from Dr. Simonis of the Charlottenburg Technische Hochschule who sent a sample of the beryllium he had used, a fourth from Dr. Hopkins of the University of Illinois, and a fifth from Dr. Stock of the Kaiser Wilhelm-Institut. Although all samples have been shown by analysis to contain at least 98% of beryllium, that provided by Dr. Stock is claimed to be the purest beryllium for which letters patent have been issued; it has been shown by analysis to contain more than 99% of beryllium.

All of the other chemicals used, particularly the ether and other solvents and the various alkyl and aryl halides, were prepared freshly in a very high state of purity. The apparatus was periodically tested in the sense that Grignard reagents were readily prepared in it, using both magnesium turnings and powder, various halides and various solvents.

The factors varied in the many studies were the halides, solvents, temperature, time of heating, and catalysts. The halides used were methyl iodide, ethyl iodide, benzyl bromide, bromobenzene, chlorobenzene and α -bromonaphthalene. In addition to the commonly used solvent, anhydrous ether, anisole, benzene and β -ethoxy-naphthalene were tried. Using the bromonaphthalene and ethoxy-naphthalene, the temperature of

⁴ Private communication.

U. S. pat., 1,427,919, Sept. 5, 1922.

one series of experiments was as high as 245–250°. The time allowed for some runs was as much as two weeks, and in the shorter runs, all of which extended over 12 hours, the material was stirred almost continuously. Conventional catalysts such as iodine, bromine, dimethyl aniline, freshly prepared Grignard reagent (sometimes directly prepared in the reaction mixture) were used repeatedly. Ethyl acetate, which is so useful in the preparation of organozinc iodides, was tried as a catalyst in one experiment.

In some experiments sublimed beryllium iodide, freshly prepared in a vacuum by subliming iodine onto heated beryllium, was used. Also, to overcome the objection that the metal might be coated with an oxide, it was shaken before use in one experiment with very dilute, pure nitric acid, and then while gas evolution continued was quickly filtered, washed, dried and used directly. In one experiment the reaction mixture was exposed to X-rays.⁶

As a final proof that conditions were as nearly satisfactory as possible for a reaction, some magnesium was added at the end of every experiment, either to a part or the whole of the reaction mixture, and in every case a reaction took place between the magnesium and halide.⁷

In no experiment was there any evidence of a reaction between the beryllium and halide.

Conclusion

The experiments outlined are sufficiently general to indicate that metallic beryllium does not enter directly into reaction with halides to form organo-beryllium halides. There are, however, several methods for the indirect preparation of organoberyllium halides, and a study is being made of such reactions.

The author wishes to acknowledge gratefully the kindness of Doctors Grignard, Simonis, Stock, Kamm, and Hopkins for the help they have given in supplying some of the metal used, and for the unpublished accounts of their work.

Summary

A series of unsuccessful attempts has been made to bring metallic beryllium into reaction with a variety of halides in an effort to prepare organoberyllium halides.

AMES, IOWA

⁶ Work done by Mr. B. Toubes.

⁷ In connection with another study, the results of which will be published shortly, a detailed account will be given of a general test for some organometallic halides.

IDENTIFICATION OF AMINES

By C. S. Marvel and F. E. Smith Received August 1, 1923

Many crystalline products are available for the identification of primary and secondary amines since most of their acetyl, benzoyl and benzene-sulfonyl derivatives are known solids. However, certain of these derivatives are not entirely satisfactory because their melting points lie too close to one another.

Benzenesulfonyl chloride has been shown¹ to be a particularly desirable reagent in the examination of amines and is almost always used in routine qualitative organic analysis of nitrogen compounds. However, some of the benzenesulfonyl derivatives of the commoner amines are oils or low-melting solids, and after application of the Hinsberg test, another solid derivative must be prepared for complete identification.

Ssolonina² has prepared the p-bromobenzenesulfonyl derivatives of a few amines and has found that as a rule these melt higher than the unbrominated compound. It was thought that p-bromobenzenesulfonyl chloride would be useful to replace benzenesulfonyl chloride in the Hinsberg test, as better melting substances could be expected.

The p-bromobenzenesulfonyl amides of most of the common amines have now been prepared and characterized. As a general rule they are easily crystallizable compounds with sharp melting points. They make especially good derivatives for ethyl aniline, n-propylaniline, n-butyl-aniline and piperidine. However, p-bromobenzenesulfonyl chloride cannot be used in place of benzenesulfonyl chloride in the Hinsberg test because it gives alkali insoluble derivatives with many primary amines. This insolubility may be explained by the theory developed by Adams³ to explain the alkali insolubility of certain phenols.

Experimental Part

p-Bromobenzenesulfonyl Chloride.⁴—This reagent is readily obtained by heating a mixture of 100 g. of sodium p-bromobenzenesulfonate and 70 g. of phosphorus pentachloride on the water-bath for about 16 hours. After the mixture has cooled, water is added to destroy the phosphorus oxychloride and the p-bromobenzenesulfonyl chloride which separates is filtered and washed with water. After the product is carefully washed it is dried. The yield is 85 to 90 g. (86–90%) of a product melting at 75°. The reagent may be recrystallized from petroleum ether if a very pure product is desired.

- ¹ Hinsberg, Ber., 23, 2963 (1890).
- ² Ssolonina, Chem. Zentr., [2] 1899, 867.
- ³ Adams, This Journal, 41, 247 (1919).
- ⁴ Ann., 180, 98 (1876).

Preparation of the p-Bromobenzenesulfonamides.—p-Bromobenzenesulfonyl chloride is treated with a slight excess of the amine and warmed if necessary to start the reaction. The reaction takes place smoothly with the evolution of heat and after a few minutes is complete. The excess amine is removed by washing the product with dil. hydrochloric acid. The crude product is then recrystallized from alcohol of the proper strength, depending on the particular compound used (see Table I).

The derivatives of methylamine, dimethylamine and piperidine are prepared by treating a water solution of the amine hydrochloride with p-bromobenzenesulfonyl chloride and aqueous alkali in the usual manner.

The new compounds that have been prepared are given in Table I, together with their physical properties and analyses.

Diethylamine gives an oily product which solidifies in an ice-bath. Since it is not of use as a derivative it was not analyzed.

THE ALLYL ETHERS OF VARIOUS CARBOHYDRATES

By C. G. Tomecko1 with Roger Adams

RECEIVED AUGUST 3, 1923

Some of the most important developments in the chemistry of carbohydrates during the past fifteen years have been through the use of the alkyl ether derivatives. The original method of alkylation, as developed by Irvine² and his co-workers, was by means of silver oxide and alkyl iodides. More recently, an improvement has been made upon this procedure by Haworth3 who has used methyl and ethyl sulfates in place of the alkyl iodides; with these reagents aqueous alkaline solutions or suspensions are employed and the preparation of the ethers is thus rendered very simple. Of especial interest may be mentioned that the ethers of the disaccharides have been used in the determination of the structure of the disaccharides; the ethers of cellulose apparently are of commercial importance and consequently their preparation by this same process has engaged the attention of many investigators. In spite of the general interest and importance of the ethers of the carbohydrates, no other ethers than the methyl and ethyl derivatives have been prepared until very recently. Gomberg and Buchler4 made the benzyl derivatives of a variety of carbohydrates, following the same procedure as with the alkyl sulfates: this was possible due to the great reactivity of the chlorine in the benzyl chloride. In that paper a review of the previous articles discussing alkylation was given. Since that time many patents⁵ have appeared on the

methylation and ethylation of cellulose, as well as numerous scientific papers involving the methylation of or ethylation of a variety of different carbohydrates.

From a practical standpoint the methyl and ethyl ethers are at present the only types which are of particular interest, but from a theoretical standpoint the preparation and study of other types of ethers should lead to important results. An investigation was undertaken in this Laboratory to prepare such ethers of the carbohydrates as contain in the ether groups other active groups through which new types of carbohydrate compounds may be prepared and studied. Such new ethers may be formed by allowing active halogen compounds to react with an alkaline solution or suspension of the carbohydrate; of these may be mentioned the first two that have been studied, allyl bromide and chloro-acetic acid.

This preliminary communication describes work on the allylation of carbohydrates with allyl bromide and sodium hydroxide. Owing to the great reactivity of the bromine, the introduction of the allyl group is extremely simple and good yields of products are obtained. The number of ether groups introduced corresponds to the number of benzyl groups introduced by benzyl chloride and sodium hydroxide.

The products resemble in physical properties the corresponding methyl and ethyl derivatives. The tetra-allyl- α -methyl glucoside is a highboiling, viscous liquid that can be distilled under diminished pressure without decomposition. Penta-allyl sucrose is a viscous oil that cannot be distilled without decomposition. Mono-allyl inulin, mono-allyl potato starch, mono-allyl corn starch, mono-allyl dextrin and allylated cellulose are practically white, amorphous substances that were purified by solution in various organic solvents and then reprecipitation with ether. They give rather indefinite decomposition points. Various derivatives of the new allyl ethers are now being studied.

No record of the preparation of allyl ethers of carbohydrates has previously appeared. The only allyl derivatives of the carbohydrates which have been mentioned are the allyl glucosides prepared by Fischer⁷ and Bourquelot.⁸

Experimental Part

One molecular equivalent of carbohydrate was dissolved or suspended in 10% sodium hydroxide containing an excess of alkali (2 to 2.5 mo-

A SAMPARA

lecular equivalents). This mixture was heated on a water-bath and stirred mechanically while an excess of allyl bromide was dropped in slowly. It was generally advisable to heat the reaction mixture on a water-bath for about an hour after all the bromide had been added. The reaction mixture was then steam distilled to remove any allyl alcohol or excess of allyl bromide, the oily or gummy reaction product washed with water and purified. The yields, properties and methods of purification are described under the individual substances.

All analyses were made on the solids after drying in a vacuum at 110° for 24 hours. It was found that two or three of the allylated compounds did not give analyses as close to the calculated values as might be expected. In these cases duplicate analyses were carried out on subsequent reprecipitations and in every instance gave check results with those analyses which are reported. This led to the conclusion that certain of the mono-allyl derivatives were contaminated, perhaps with small amounts of higher allylated compounds which had very similar properties to the mono-allyl derivatives and were not removed by the precipitations.

None of the solids prepared had a definite melting or decomposition point. Since melting points were reported for the benzylated compounds⁴ two or three of these were made in this Laboratory and the effect of temperature determined. The points mentioned by these authors as melting points are unquestionably points of decomposition resembling closely the type of decomposition found for the allylated compounds. The "melting points" reported for the benzyl compounds are actually the points where the various materials start to shrink.

Tetra-allyl- α -methyl Glucoside.—From 100 g. of α -methyl glucoside, 249 g. of allyl bromide and 124 g. of sodium hydroxide, there was obtained 83 g. of purified tetra-allyl- α -methyl glucoside boiling at 182° (1.5 mm.); $n_{\rm D}^{18}$, 1.4836; d_{20}^{20} , 1.1519; $[\alpha]_{\rm D}^{30}$, 116.5° (in absolute alcohol). It is a thick, colorless oil, insoluble in water but soluble in alcohol and ether.

Analyses. Subs., 0.1503: CO_2 , 0.3160; H_2O , 0.1070, Calc. for $C_{19}H_{30}O_4$: C, 64.41, H, 8.47. Found: C, 64.13; H, 7.93.

Penta-allyl Sucrose.—From 100 g. of sucrose, 340 g. of allyl bromide and 141 g. of sodium hydroxide there was produced 118 g. of the penta-allyl derivative. The crude reaction product was taken up in chloroform, filtered and the chloroform evaporated. There was thus formed a practically colorless, thick oil which could not be distilled under diminished pressure without decomposition. It was insoluble in water but soluble in alcohol and ether.

Analyses. Subs., 0.4710: CO₂, 1.0232; H_2O , 0.3056. Calc. for $C_{27}H_{42}O_{11}$: C, 59.59; H, 7.74. Found: C, 59.21; H, 7.58.

Mono-allyl Dextrin.—From 25 g. of dextrin, 100 g. of allyl bromide and 75 g. of sodium hydroxide there was obtained 16 g. of allylated dextrin. The crude product formed a gummy mass. This was purified by dissolving it in chloroform and precipitating with ether. After a number of such treatments a practically white, amorphous solid was obtained, shrinking at 155–165° and gradually decomposing at about 240–250°.

Analyses. Subs., 0.3876: CO_2 , 0.7334; H_2O , 0.2260. Calc. for $C_{18}H_{24}O_{10}$: C, 49.44; H, 6.59. Found: C, 51.41; H, 6.43.

Mono-allyl Inulin.—From 10 g. of inulin, 100 g. of allyl bromide and 75 g. of sodium hydroxide there was obtained about 5 g. of gummy product. When this was treated with a limited amount of cold alcohol, it dissolved and was then reprecipitated with ether. Care must be taken not to add too much alcohol as such an excess also causes precipitation. Further purification was effected by dissolving the material in glacial acetic acid and reprecipitating it with ether. There was thus produced 3 g. of nearly white product, shrinking at 150–155° and decomposing at 205–210°.

Analyses. Subs., 0.3014: CO_2 , 0.5330; H_2O , 0.1898. Calc. for $C_{15}H_{24}O_{10}$: C, 49.44; H, 6.59. Found: C, 48.22; H, 7.00.

Mono-allyl Potato Starch.—From 10 g. of potato starch, 85 g. of allyl bromide and 50 g. of potassium hydroxide, a gummy product was produced. This was dissolved in alcohol as described under allyl inulin and reprecipitated with ether, then twice dissolved in glacial acetic acid and reprecipitated with ether. The final product was practically white and weighed 10 g. It shrank at 160–165° and decomposed without melting at about 260–270°.

Analyses. Subs., 0.3470: CO₂, 0.6318; H_2O , 0.2054. Calc. for $C_{15}H_{24}O_{10}$: C, 49.44; H, 6.59. Found: C, 49.64, H, 6.55.

Mono-allyl Corn Starch.—From 10 g. of corn starch, 110 g. of allyl bromide and 75 g. of potassium hydroxide there was obtained a gummy product which was purified like the mono-allyl potato starch. A practically white, amorphous product resulted which weighed 12 g. It became brown at about 250–265 $^{\circ}$ but did not shrink or melt.

Analyses. Subs., 0.3447: CO₂, 0.5699; H_2O , 0.1853. Calc. for $C_{18}H_{24}O_{10}$: C, 49.44; H, 6.59. Found: C, 50.41; H, 6.70.

Allylated Cellulose.—Pure filter paper was hydrated by dissolving it in cuprammonium hydroxide and precipitating in the usual way. From 10 g. of this precipitated cellulose, 85 g. of allyl bromide and 65 g. of potassium hydroxide there was obtained a residue which was treated with several portions of cuprammonium hydroxide. The material that remained undissolved was carefully dried and analyzed.

Analyses. Subs., 0.3852: CO₂, 0.6313; H_2O , 0.2211. Calc. for $C_{15}H_{24}O_{10}$: C, 49.44; H, 6.59. Found: C, 45.15; H, 6.44.

The product was obviously impure as shown by the analysis, but this was unquestionably due to the fact that no solvent for crystallization was found.

Summary

Several different types of carbohydrates have been treated in aqueous alkaline solution or suspension with allyl bromide. Under these conditions allyl derivatives of these carbohydrates are produced.

STUDIES ON CATALYSIS. III. THE REDUCTION OF URACIL TO HYDRO-URACIL

By Elmer B. Brown and Treat B. Johnson Received August 6, 1923

In a preliminary paper ^{1a} the writers have reported a new method of reducing the pyrimidine, uracil (I). They have applied Skita's method of catalytic reduction and have shown that this substance is reduced quantitatively with hydrogen to hydro-uracil (II) in the presence of colloidal platinum or palladium. In this paper, which is a report of their experimental work on this compound, the writers have extended their study of this catalytic reduction process, using uracil in order to establish the limiting conditions under which the reduction process in the presence of colloidal platinum or palladium can be carried out when applied to the

pyrimidine series. In the experimental part of the paper are recorded the results of our experiments showing the influence on the progress of the reduction of different foreign substances that are commonly met as impurities in the naturally occurring products containing the pyrimidines, thymine, cytosine and uracil. Sulfur compounds, which are of very common occurrence in nature and are often found as impurities in the solutions obtained in the isolation of the pyrimidines from that source, as well as in our synthetic methods of preparation, are shown to prevent reduction completely when present even in traces. The effect of the presence of thiopyrimidines and other sulfur combinations on the reduction process is similar to the results obtained by Willstätter and Hatt,² who found that traces of thiophene, for example, completely stopped the hydrogenation of benzene when platinum black was used as catalyst. The chlorides of sodium, potassium, calcium and magnesium exert no influence upon the reduction process in the case of uracil.

The reduction of uracil to hydro-uracil proceeds quantitatively when carried out under the conditions described in this paper and, so far as the writers are aware, no other method of bringing about this change successfully is available. Electrolytic reduction methods have been applied with success in the barbituric acid series, and hydro-uracil has been prepared, for example, by electrolytic reduction in acid solution of several

¹ Previous publications: (a) Johnson and Brown, *Proc. Nat. Acad. Sci.*, 7, 75 (1921); (b) Gilfillan, This Journal, 44, 1323 (1922).

² Willstätter and Hatt, Ber., 45, 1471 (1912).

pyrimidines, namely, barbituric acid, dialuric acid, uramil and alloxan, but secondary products were always formed in these operations, and the yield of hydro-uracil was generally very low.3 In fact, it has been shown that hydro-uracil can be reduced still further with formation of trimethylene-urea. The reduction of uracil to this substance can probably be accomplished by our method but apparently with great difficulty only, and at present conditions have not been established whereby it has been possible to obtain this cycle in satisfactory yields for synthetic work. The fact that uracil can be reduced so easily to hydro-uracil is of special interest to us from a biochemical point of view. If the catalytic method of reduction can be shown to be one of general application in the uracil series we will have opened up a method of synthesizing β -amino acids which will prove of great practical interest. These reduced pyrimidines bear a similar relationship to β -amino acids that the hydantoins do to α -amino acids, and on hydrolysis with acids or bases are susceptible to the same hydrolytic change. This relationship is revealed by examination of the following equations.

NH—CO
$$\rightarrow$$
 NH₂ COOH \rightarrow NH₂ COOH \rightarrow NH₃ + CO₂ + NH₂CH(R)COOH (1) NH—CHR \rightarrow NH—CHR \rightarrow NH—CHR \rightarrow NH—CHR \rightarrow NH—CHR \rightarrow NH—CO \rightarrow NH₂ COOH \rightarrow CO \rightarrow NH₂ COOH \rightarrow CO \rightarrow NH₂ COOH \rightarrow NH—CH₂ \rightarrow NH₂ \rightarrow N

Process 2 offers greater possibilities for amino acid synthesis than the hydantoin method which has been developed so extensively in the Yale Laboratories, because two carbon atoms are available to which substituent groups or radicals may be attached. Having available the proper uracil derivative, and an easy practical method of reduction at the double

bond in Positions 3 and 4, it will be possible to synthesize by our method several β -amino acids which are unknown, and are not easily obtained by the present methods of synthesis at our command. This investigation is being continued in the Sterling Chemistry Laboratory.

Experimental Part

Purification of Uracil.—The pyrimidine used in this research was prepared by students in the laboratory by application of the thio-urea method and was of a fair degree

³ Tafel and Weinschank, Ber., 33, 3385 (1900). Tafel and Reindl, ibid., 34, 3286 (1901).

of purity, although not of sufficient purity to permit its use in our catalytic reduction work. One hundred g. of uracil was repeatedly recrystallized from water, using Norite to remove all coloring material, when a product was easily obtained which failed to respond to the sulfur test and was apparently free from this impurity. However, in order to remove the minutest trace of sulfur impurities, 50 g. of the product described above was further purified by refluxing for 3 hours with a 2% solution of monochloro-acetic acid and then recrystallizing twice from water. In this manner we obtained a colorless sulfur-free product which caused no difficulty in our reduction operations.

The Reduction of Uracil to Hydro-uracil.—Six g. of pure uracil is placed in the reduction flask, and to this 2 g. of gum arabic dissolved in 50 cc. of hot water, 10 cc. of 10% chloroplatinic acid solution and 150 cc. of water is added. The reduction flask is then placed in position in an electric heater on a shaking machine and connected with a cylinder of hydrogen. After removal of the air from the reduction flask hydrogen is introduced until a pressure of two atmospheres is obtained, the shaking machine is then started and the electric current turned on. Within a short time the solution turns black and there is very rapid absorption of hydrogen and the formation of colloidal platinum. The temperature is soon increased to 75°, and maintained at that point by proper regulation of the electric current. The calculated amount of hydrogen is absorbed in 5 to 7 hours, and the absorption ceases under the above conditions when one molecular equivalent of hydrogen has been taken up.

The reduction solution is now poured into an equal volume of acetone and the precipitated colloid allowed to settle. Usually one hour suffices for complete separation of the colloid, leaving a clear solution which is easily filtered. The acetone is distilled and can be used for the same purpose again without further purification. The aqueous filtrate is evaporated to a small volume on the water-bath and allowed to cool. A beautiful white crystalline product quickly deposits, weighing from 5.6 to 5.8 g., depending on the volume of the solution. When recrystallized from water this separates in the form of large, transparent, 4-sided plates and melts at 272–274°, the correct melting point of hydro-uracil.

Analysis. Calc. for C₄H₆O₂N₂: N, 24.56. Found (Kjeldahl): 24.69.

The calculated quantity of hydro-uracil is never obtained in these reductions; this is due to the fact that the gum arabic is partially decomposed during the evaporation of the hydrochloric acid solution giving a sirup which always retains a small amount of pyrimidine that cannot be recovered. That the reduction, however, is quantitative is shown by the application of Wheeler and Johnson's color test to the reduction solution. When 3 cc. of the solution, corresponding to 0.09 g. of pyrimidine, is added to an equal volume of acetone to remove the platinum, and the color test is then applied no purple condensation product is obtained, showing the absence of unreduced product. One mg. of uracil gives a decided bluish-pink or lavender color within a short time when subjected to a similar treatment.

The Colloid Support.—In order to study the effect of various amounts of gum arabic on the progress of the reduction of uracil to hydro-uracil a series of experiments was performed using in each case 3 g. of uracil,

Gum arabic, g	0.2	0.5	1.0	2.0	5.0
H ₂ absorbed, cm	21.2	24.5	23.3	22.4	17.3
(1 cm. equals 26 cc. of hydrogen un					

^{*}A special equipment was constructed for our work whereby several experiments can be run independently at the same time.

100 cc. of water, 10 cc. of 10% chloroplatinic acid and various amounts of gum arabic. The time of each run was 7 hours and 40 minutes.

In each of the above experiments the platinum remained in the colloidal state throughout the operations and the results show that the rate of absorption of hydrogen is not materially affected by the quantity of gum arabic used. Rideal⁵ states that there is an optimum amount of gum arabic for each catalyst, corresponding to about 4 mg. per 10 mg. of platinum, and that amounts in excess of this tend to retard the rate of absorption of hydrogen. He arrived at this conclusion from results obtained during the study of the reduction of the propiolic acid. Our results show that concentrations of gum arabic 25 times as great as those that retarded or stopped the reduction of propiolic acid exerted very little, if any, influence on the reduction of uracil to hydro-uracil, and that such an optimum does not exist in the case of this pyrimidine.

Several experiments were made in an effort to substitute pepsin and trypsin for gum arabic as colloid supports in the reduction of uracil to hydrouracil. For example, 3 g. of uracil, 0.5 gm. pepsin, 100 cc. of water and 5 cc. of chloroplatinic acid were used in one experiment. During 2 hours and 15 minutes an absorption of 1 cm. (26 cc.) had taken place. The platinum had separated and fallen to the bottom of the flask, so 3 cc. more chloroplatinic acid was added and during the next 2 hours and 40 minutes an absorption of 5.3 cm. (138 cc.) was obtained, making a total of 6.3 cm. Gum arabic was then added with more chloroplatinic acid and the reduction completed. The absorption was much slower than usual, showing that pepsin probably exerts an anticatalytic effect. When this experiment was duplicated, using gum arabic as colloid support, an absorption of 23 cm. was obtained in the same length of time, using only 5 cc. of chloroplatinic acid as catalyst.

In a similar experiment using trypsin as colloid support an absorption of 9.6 cm. was obtained during a run of $7^1/_2$ hours, with 5 cc. of chloroplatinic acid, at the end of which time the platinum had completely separated. Gum arabic and 2 cc. more of chloroplatinic acid were then added and the reduction carried to completion. The reduction proceeded normally after the addition of the gum arabic, showing that the trypsin had no anticatalytic effect, as was observed in the case of pepsin.

Effect of Temperature and Shaking on the Rate of Absorption of Hydrogen.—Three g. of uracil, 0.5 g. of gum arabic, 100 cc. of water and 5 cc. of 10% chloroplatinic acid were placed in the reduction flask and the reduction started as in previous experiments. During one hour and 40 minutes 75 cc. of hydrogen was absorbed, which corresponds practically to the quantity necessary for the reduction of the platinic acid to colloidal platinum. No further absorption took place at ordinary temperature.

⁵ Rideal, This Journal, 42, 749 (1920).

An increase in temperature caused an immediate increase in absorption of hydrogen, and at 75° the rate was normal and continuous until 600 cc. of hydrogen gas was taken up. In other words, the rate of reduction is increased by rise in temperature. Furthermore, it is not necessary to increase the proportions of the catalyst to produce this effect.

The rate of hydrogen absorption is also influenced greatly by the intensity of agitation or shaking. In an experiment in which the motion of the reduction flask was controlled by means of lights placed in the armature circuit of the motor so as to produce a moderate or a rapid vibration of the reduction flask, it was observed that the rate of absorption could be increased 100% by intense agitation. Within 45 minutes an absorption of 175 cc. of gas was obtained when a 60-watt lamp was introduced into the armature circuit, while 405 cc. of hydrogen was absorbed in the same period of time when this light was replaced with a 100-watt lamp. Using the same proportions of reagents as above, it was found that by rapidly shaking the mixture it was possible to bring about an absorption of the calculated volume of hydrogen (600 cc.) in 1.5 hours at 75° .

Effect of Chlorides of Sodium, Potassium, Calcium and Magnesium, and of Sulfur Compounds on the Reduction of Uracil.—In a series of experiments using 3 g. of uracil, 1 g. of gum arabic, 100 cc. of water, 10 cc. of 10% chloroplatinic acid and 1 g. each of sodium, potassium, calcium and magnesium chlorides it was observed that these chlorides exerted no influence on the progress of the reduction of uracil to hydro-uracil. The reduction in each case was complete and the calculated amount of hydrogen was absorbed in the same time required for the reduction of uracil in the absence of the above salts. From 2.6 to 2.9 g. of hydro-uracil was isolated from each experiment, showing that the presence of the salts adds no difficulties in the isolation of the hydro-uracil.

In an experiment in which a sample of uracil was used containing enough thio-uracil to be detected by the nitroprusside test, an absorption of hydrogen equal to the amount required for the reduction of the chloroplatinic acid was obtained, showing that sulfur even in such small amounts completely prevents the reduction. This same sample after purification to remove sulfur (negative nitroprusside test) and repeated recrystallizations from water could then be reduced, but it required twice the platinum concentration for reduction that it did after further purification by boiling with monochloro-acetic acid which insures the complete removal of the sulfur. In an attempt to reduce pure thio-uracil a colloidal solution of the platinum was not obtained during 7 hours' treatment, using the same conditions as described above. No reduction was obtained when the platinum was first reduced to the colloidal state and the thio-uracil then added, even with much larger concentrations of platinum.

Effect of the Addition of Catalyst in Portions on the Reduction of Uracil

Containing Traces of Sulfur.—The following experiments were made on a sample of uracil containing traces of thio-uracil; in each experiment 6 g. of uracil, 2 g. of gum arabic and 200 cc. of water were used and the chloroplatinic acid was added as described below; otherwise the conditions of the experiments were the same as in the preceding reductions. With 12 cc. of chloroplatinic acid an absorption of 300 cc. of hydrogen was obtained in 2 hours, at the end of which time the absorption had practically ceased, so 10 cc. more of chloroplatinic acid was added. During the next 5 hours 900 cc. of hydrogen was absorbed, bringing the total to 1200 cc., the calculated amount required for complete reduction of the pyrimidine. In another experiment, after the addition of 22 cc. of chloroplatinic acid at first the reduction proceeded for 5 hours before coming to a standstill and 650 cc. of hydrogen was absorbed. Five cc. more of chloroplatinic acid carried the reduction to the end in 4 hours in which time 550 cc. of hydrogen was absorbed. A total of 27 cc. of chloroplatinic acid was required for the complete reduction. In another experiment in which the chloroplatinic acid was added in portions of 5, 7, 5 and 3 cc. the final absorptions were 40, 380, 500 and 320 cc. of hydrogen, respectively. Only 20 cc. of chloroplatinic acid was required for complete reduction. When this was added in portions of 12, 5 and 3 cc., the corresponding absorptions were 240, 650 and 350 cc. during $1^3/4$, 4 and $2^1/2$ hours, respectively. From each of the above experiments hydro-uracil was isolated in amounts varying from 5.6 g. to 5.9 g., showing that the reduction proceeded to completion in each case. These experiments show that better reduction is obtained when the catalyst is added in portions to compounds containing small amounts of "poisons" than all at the same time.

The Influence of the Solvent on the Reduction of Uracil in the Presence of Colloidal Platinum and Palladium.—The solubility of uracil in the different solvents is, as a rule, so small that only a few solvents are suitable for the reduction work. This is especially true of the organic liquids in which uracil is practically insoluble. The best solvent for uracil is water, in which the solubility is not appreciably affected by the presence of acids, but is greatly increased by alkalies; hence a study of the reduction process in alkaline solution, if successful, would add greatly to the production of hydro-uracil in quantity.

A number of experiments were carried out in alkaline solution in an effort to reduce this pyrimidine, and in none was there any evidence of the absorption of hydrogen after the amount necessary for the reduction of the chloroplatinic acid or palladium chloride used as the catalyst, in runs varying from one to three days, using the conditions employed in the preceding experiments.

In experiments carried out with glacial acetic acid, as well as dilute acetic acid of different strengths as solvents, it was shown that this medium is

equally good but no better than water for the reduction of uracil. Various strengths of hydrochloric acid when added to the reduction solution produced no effect on the reduction. Of course, in each of the experiments except those carried out in alkaline solution some hydrochloric acid was present resulting from the reduction of the chloroplatinic acid.

Experiments carried out under identical conditions showed that the reduction proceeded more rapidly with colloidal platinum than with colloidal palladium when equal weights of the two materials were used; however, the differences were never large and both are applicable for the reduction of uracil to hydro-uracil.

Summary

- 1. Uracil is converted quantitatively into hydro-uracil (β -lactylurea) by treatment with hydrogen in the presence of colloidal platinum or palladium.
- 2. Since hydro-uracil has been shown to undergo hydrolysis smoothly to β -alanine⁶ our method of reduction, therefore, offers an easy and practical method of converting uracil directly into β -alanine. From a biochemical point of view this result is one of especial interest and importance.

BETA-PHENOXYPROPIONIC ACID AND SOME OF ITS DERIVATIVES. CHROMANONE

By S. G. POWELL RECEIVED AUGUST 6, 1923

In the course of an investigation of certain unsaturated phenyl ethers, which is to be reported later, a considerable quantity of β -phenoxypropionic acid was required. The only method then available for the preparation of this compound was that of Bischoff¹ which depends upon the action of sodium phenoxide on sodium β -iodopropionate. Unfortunately, the latter is difficult to obtain; moreover, the yield of β -phenoxypropionic acid under the most favorable conditions is only 20%. This paper describes a convenient method for obtaining this acid from the corresponding alcohol.

In preparing some derivatives of the acid, an attempt to purify a sample of β -phenoxypropionyl chloride by distillation resulted in the isolation of the hitherto unknown chromanone. This compound and some of its derivatives are also described.

⁶ Weidel and Roithner, Monatsh., 17, 183 (1986). Lengfeld and Stieglitz, Am. Chem. J., 15, 221, 517 (1893).

¹ Bischoff, Ber., 33, 928 (1900).

Attempts to oxidize γ -phenoxypropyl alcohol with alkaline permanganate by the method of Fournier² were not successful. Oxidation with neutral permanganate, however, gave results which were highly satisfactory, although by no means quantitative. It should be mentioned here that this method is being further investigated, not only as applied to this acid, but also to other β -aryloxy fatty acids. The yield by the method described in this paper varies between 32 and 45% when 10 g. or less of the alcohol is oxidized at one time, but falls off materially when larger quantities are used. Thus 10 g. of the alcohol gave 5 g. of the acid, whereas 40 g. gave only 7 g. As the success of the oxidation depends upon keeping the temperature low, the poorer yield in the larger runs may be due to imperfect cooling of the larger volume of solution. In the smaller runs the yield was not improved by using an excess of permanganate, although about half of the alcohol was recovered unchanged.

+ HCl. This compound is more readily obtained, however, by the dehydration of the free acid by means of phosphorus pentoxide. It resembles very closely the 6-methyl-chromanone described by V. Auwers and Krollpfeiffer.³ Thus, it reacts normally as a ketone with hydroxylamine forming an oxime, and condenses with benzaldehyde to benzal-chromanone.

The preparation of other chromanones and their derivatives by this same general method will be described in a later paper.

Experimental Part

 γ -Phenoxypropyl Alcohol, C₆H₅OCH₂CH₂CH₂OH.—The γ -phenoxypropyl alcohol used in this work was prepared by a modification of the method described by Rindfusz⁴ who obtained it in 75% yield by treating an absolute alcoholic solution of sodium phenoxide with trimethylene chlorohydrin. By using an aqueous solution of sodium phenoxide, in which the chlorohydrin is completely soluble, the use of metallic sodium and absolute alcohol is avoided, the reaction is completed in a much shorter time, and slightly better yields are obtained.

To a solution of 250 g. of phenol in 1000 g. of 10% aqueous sodium hydroxide is added 188 g. of trimethylene chlorohydrin, and the clear solution is heated to boiling under a reflux condenser. About 3 minutes after the solution begins to boil it separates into two layers and the reaction is practically complete at this point. To insure com-

³ Auwers and Krollpfeiffer, Ber., 47, 2585 (1914).

⁴ Rindfusz, This Journal, 41, 668 (1919).

plete reaction, however, the boiling is continued for 30 minutes. The mixture is cooled, the phenoxypropyl alcohol taken up in ether, the ether solution washed with dil. sodium hydroxide solution, then with water, and finally dried over sodium sulfate. After removing the ether, the oily residue is heated when the phenoxypropyl alcohol distils at 160° (25 mm.); yield, 240 g., or 80%.

β-Phenoxypropionic Acid, $C_6H_5OCH_2CH_2COOH$.—This compound has been prepared by Bischoff¹ who obtained it by treating sodium β-iodopropionate with sodium phenoxide. It is more conveniently prepared by the oxidation of the corresponding alcohol by the following method.

Ten g. of γ -phenoxypropyl alcohol is added to a solution of 30 g. of crystallized magnesium sulfate in 100 cc. of water contained in a narrow bottle immersed in a pan of cold water. The mixture is kept well stirred with a mechanical stirrer, and 280 cc. of 5% potassium permanganate solution is added drop by drop over a period of several hours, while the temperature is maintained at about 15–20°. The stirring is continued until the color of the permanganate disappears. A slight excess of sodium bisulfite is then added and the mixture is acidified with 50% sulfuric acid, when the β -phenoxypropionic acid separates as an oil which partially solidifies as it cools. The oily mass is dissolved in ether and the ether solution extracted with 5% sodium hydroxide solution. The alkaline extract is acidified with dil. sulfuric acid when the phenoxypropionic acid separates in shiny, needle-like crystals. After the mixture has cooled, the acid is filtered off and recrystallized from hot water from which it separates in long needles melting at 98°. The yield varies between 3.5 g. (32%) and 5 g. (45%). The ether solution from which the acid has been extracted contains unoxidized alcohol, which is recovered and treated again.

Ethyl β-Phenoxypropionate, C₆H₅OCH₂CH₂COOC₂H₅.—Forty g. of the acid is dissolved in 400 cc. of absolute alcohol previously saturated with dry hydrogen chloride and the solution boiled under a reflux condenser for one hour. Most of the alcohol is then distilled, the residue diluted with water, and the ester taken up in ether. The ether solution is washed with dil. sodium carbonate solution, then with water, and finally dried over sodium sulfate. After removal of the ether, the residue is heated, when the ester distils to the last drop at 170° (40 mm.). The product is a colorless oil with a characteristic, very persistent odor; yield, 42 g., or 90%.

Analysis. Subs., 0.2009: CO₂, 0.5020; H_2O , 0.1432. Calc. for $C_{11}H_{14}O_3$: C, 68.1; H, 7.2. Found: C, 68.1; H, 7.9.

β-Phenoxypropionyl Chloride, $C_6H_0OCH_2CH_2COC1$.—A solution of 20 g. of β-phenoxypropionic acid in 60 g. of thionyl chloride is heated to 100° for 30 minutes, and then distilled. Two main fractions are obtained, one boiling at 159–160° (50 mm.) and the other boiling at 237° (50 mm.). The lower-boiling fraction is chromanone, while the higher-boiling has not been further investigated except to determine that it is halogen-free. When, however, the acid is gently warmed for a few seconds with only a slight excess of thionyl chloride, a liquid of irritating odor is produced which yields the corresponding amide with ammonia.

 β -Phenoxypropionamide, $C_6H_5OCH_2CH_2CONH_2$.—The crude reaction mixture from 3 g. of the acid and 3 g. of thionyl chloride is added drop by drop to an excess of concd. aqueous ammonia. After standing overnight, the precipitated amide is filtered off and recrystallized from hot water, from which it separates in shiny needles melting at 119°.

Analysis. Subs., 0.5110: 30.6 cc. of 0.1 N H_2SO_4 . Calc. for $C_9H_{11}O_2N$: N, 8.48. Found: 8.38.

Chromanone.—To a solution of 25 g. of β -phenoxypropionic acid in 200 cc. of dry benzene, 50 g. of phosphorus pentoxide is added, and the mixture is refluxed for one hour. The benzene solution is decanted and the dark colored mass of phosphorus compounds extracted several times with boiling benzene. The united benzene solutions are washed with a little dil. sodium hydroxide solution, then with water and finally dried with a little calcium chloride. The benzene is removed by distillation from the waterbath and the residue distilled. The chromanone forms a colorless, highly-refracting liquid, with a very pleasant lemon-like odor. It boils at 160° (50 mm.) and on standing solidifies to a mass of hard crystals melting at 38.5° .

Analysis. Subs., 0.2554: CO₂, 0.6810; H₂O, 0.1287. Calc. for $C_0H_8O_2$: C, 73.0; H, 5.4. Found: C, 72.7; H, 5.6.

Chromanone Oxime.—Three g. of chromanone and 3 g. of hydroxylamine hydrochloride are dissolved in 50 cc. of alcohol, 6 g. of potassium carbonate is added and the whole boiled under a reflux condenser on the water-bath for 6 hours. The product is poured into water when the oxime separates and is filtered off. It is purified by dissolving it in hot benzene and precipitating with petroleum ether. It forms glistening, needle-like crystals melting at 140°.

Analysis. Subs., 0.2416: (Kjeldahl) 14.5 cc. of 0.1 N H₂SO₄. Calc. for C₉H₈O₂N: N. 8.6. Found: 8.4.

Benzal-chromanone.—Three g. of chromanone and 4 g. of benzaldehyde are dissolved in 50 cc. of alcohol, the solution is heated almost to boiling, and 10 cc. of coned. hydrochloric acid added drop by drop. After standing for several days the benzal-chromanone which has separated is filtered off and recrystallized from alcohol, from which it separates in long yellow needles melting at 112°.

Analysis. Subs., 0.2130: CO_2 , 0.6314; H_2O , 0.1034. Calc. for $C_{18}H_{12}O_2$: C, 81.4; H, 5.1. Found: C, 80.9; H, 5.4.

Summary

- 1. The method of preparation of γ -phenoxypropyl alcohol has been simplified.
- 2. β -Phenoxypropionic acid has been prepared by oxidation of the corresponding alcohol.
 - 3. Some derivatives of β -phenoxypropionic acid have been prepared.
 - 4. Chromanone and some of its derivatives have been prepared.

SEATTLE, WASHINGTON

[Contribution from the Department of Chemistry, Columbia University, No. 423]

EXPERIMENTS WITH TWO METHODS FOR THE STUDY OF VITAMIN B

By H. C. Sherman and Harriet Edgeworth Received August 6, 1923

The further progress of our knowledge of the vitamine must depend largely upon the development of methods for the experimental study of these substances which shall be both practicable and quantitative. When such methods are sufficiently developed they can be applied to the quantitative measurement of the concentration of the vitamin at successive steps in attempts to isolate the substance from natural sources and bring it to a condition of maximum purity for the determination of its chemical nature. Moreover, the importance of vitamin B as a factor in food values makes it urgently desirable that quantitative methods of known precision be applied in all studies of the vitamin contents of different foods or of the same food before and after heating or other treatment to which foods may be subjected.

As has been fully explained elsewhere^{1,2} such methods imply feeding to a suitable organism, in or with an otherwise adequate diet, known amounts or proportions of the material to be tested as the sole source of the vitamin in question.

In this and the two following papers dealing with vitamin B, we use this term to designate the growth-promoting, water-soluble B vitamin without regard to the question as to whether this is or is not identical with the antineuritic substance. Hence, we have taken the growth of young rats rather than the prevention or cure of polyneuritis in pigeons as our principal criterion. Several investigators have worked actively in the belief³ that experiments based on acceleration of yeast growth could serve the same purpose as those based on rat growth and in a quicker, more economical and more readily controllable way. Different methods of ascertaining the stimulating or growth-promoting effect of the vitamin upon the yeast were proposed: (a) counting the cells produced; (b) measuring the carbon dioxide produced; (c) measuring the increase in volume of yeast cells; (d) weighing to determine the increase in yeast gravimetrically.

The counting of yeast cells, even as reported by those who have appeared to have most confidence in this method, has yielded data showing such wide variations in duplicate tests as to preclude its employment in quantitative investigations.

- ¹ Chick and Hume, J. Biol. Chem., 39, 203 (1919).
- ² Sherman, LaMer and Campbell, This Journal, 44, 165 (1922).
- ³ For further discussion, see Sherman and Smith, "The Vitamins," Chemical Catalogue Company, New York, 1922, pp. 72-75.

In the estimation of yeast growth (or activity) by measurement of the carbon dioxide produced, there is the difficulty that the difference in carbon dioxide pressure at the two surfaces of the liquid in the fermentation tube permits a loss of carbon dioxide by passage through the solution. Obviously also even small changes in temperature may result in further error. This method therefore does not seem promising from a quantitative point of view.

In measuring the volume of the yeast, the fact that yeast-substance is largely protein, having an iso-electric point on either side of which it will show differences in amount of swelling, depending on the hydrogen-ion concentration of the medium, must be taken into account and plainly detracts much from the ease and precision which might otherwise be expected of this method.

The gravimetric method seemed, therefore, the most promising from the standpoint of quantitative accuracy of results.

Yeast was made up for seeding from a Fleischmann yeast cake according to the method of Williams, 4 and was grown for 18 hours at 30° in a constant-temperature oven, in one of the two media described below.

As source of vitamin B we selected dried skimmed milk, as a material readily available and easily kept uniform throughout the investigation, easy and accurate of manipulation, and usable either in the dry state or reconstituted as fluid skimmed milk by mixing with nine times its weight of water. It was desired to employ a typical and natural form of vitamin B free from any danger of having been altered or fractioned by chemical or physical treatment. It was also thought best, in view of the experience of this and other laboratories and of Osborne's suggestion that vitamin B may occur naturally in chemical combination with the proteins of some foods, to avoid the use of any method which should involve the necessity of employing extracts of the food to be tested.

Experiments with the Growth of Yeast

Using the Medium of Williams.—This medium contains asparagine, 1.5 g.; calcium chloride, 0.25 g.; magnesium sulfate, 0.25 g.; monopotassium orthophosphate, 2.0 g.; ammonium sulfate, 3.0 g.; and sugar 20.0 g. per 100 cc. It was made up in lots of one liter divided into aliquot portions of 100 cc. each, placed in Erlenmeyer flasks stoppered with cotton and sterilized in an autoclave at 10 pounds' pressure for 15 minutes. To each portion, when cooled to 30°, was added 1 cc. of yeast suspension containing 0.3 mg. of yeast prepared according to the method of Williams. These portions were then incubated at 30° for 18 hours, at the end of which time 1 cc. of U.S.P. formaldehyde was added to each flask to prevent further growth of the yeast, and the contents were subsequently filtered through

4 Williams, J. Biol. Chem., 42, 259 (1920).

a weighed Gooch crucible prepared according to Williams, washed, and dried at 102° to constant weight. Parallel tests were made with the addition of various amounts of the skimmed milk used as source of vitamin B, sometimes as purchased, sometimes after heating for 6, 12, 24, or 48 hours at 100°. The control involved two tests (1) of medium and yeast without added source of vitamin, (2) of medium plus the amount of milk used as source of vitamin in each experiment.

As this medium itself contained no insoluble material, the sum of the weights obtained in the two control tests just mentioned was taken as the correction to be subtracted from the gross weighing obtained in each test, the remainder showing the amount of yeast growth due to the material added as source of vitamin.

The concentrations of hydrogen ion in (a) the control with yeast only, (b) the medium plus yeast plus 0.4 g. of unheated skim milk powder, (c) the medium plus yeast plus 0.4 g. of skim milk powder heated for 48 hours at 100°, were determined before and after incubation and found to be (a) before incubation, PH 4.4; after incubation, PH 5.5; (b) before, PH 5.7; after, PH 7.1; (c) before, PH 5.5; after, PH 7.0.

While the media seem to become slightly less acid during the process of incubation, the change is not such as to interfere with the correction of results for precipitated milk protein as described above.

In a series of determinations in which 0.4 g. of the milk powder was tested, the average results were as follows.

	G.
Wt. of insoluble matter from medium + yeast	0.0030
Wt. of insoluble matter from medium + milk	1088
Total wt. to be subtracted	
Average gross wt. in tests	
Accelerated growth due to the milk	0454

The average results of about 200 quantitative tests made by this method with or without the introduction of various amounts of the milk powder as source of vitamin B are shown in Table I.

It will be seen that the results are such as amply to justify quantitative discussion. The averages of the total, and of the accelerated growths observed show probable errors which in all cases are less than 2%, and in most cases are less than 1% of the quantities concerned. The accelerated growth of the yeast shows progressive increase with the quantity of milk powder added up to 0.4 g. This amount was therefore used in testing for the effect of heat upon the vitamin B content of the milk powder as indicated by this method. The effects attributable to heating at 100° for from 12 to 48 hours are in our judgment too small to permit of definite conclusions as to whether a measurable amount of vitamin B was thus destroyed.

Thus our experiments show that the growth of yeast in the Williams medium is a process capable of acceleration by the addition of vitamin-containing material and that this acceleration of yeast growth can be determined gravimetrically with a satisfactory degree of precision. As yet, however, there is not sufficient evidence that the Williams medium

^a Computed according to the classical method as described, for example, by Jevons, "Principles of Science," The MacMillan Co., London and New York, 1905, p. 387.

contains such favorable proportions of all other essential nutrients as to justify the assumption that acceleration of growth upon addition of food material to this medium is necessarily attributable solely to the introduction of vitamin B, and the experiments of Fulmer and his co-workers^{5,6} published while our own work was in progress tend strongly to the opposite view. Experiments with the medium of Fulmer, Nelson and Sherwood were therefore undertaken.

Using the Medium of Fulmer, Nelson and Sherwood.—For the reason above given, the method of counting cells did not seem suitable for our work and we have, therefore, tried to adapt the gravimetric method to the use of this medium, which contains undissolved calcium carbonate and precipitated phosphate. These insoluble buffers apparently yield variable amounts of residue at the end of the incubation period, for neither by drying and weighing nor by ignition of the dry residue and subtraction of the mineral matter, were we able to obtain satisfactory gravimetric measurements of yeast growth when this medium was used.

Experiments with Growth of Rats

The rat was preferred as experimental animal because it has been best standardized by previous work. Several rats of the same litter and approximately the same size were, when 28 to 30 days old, divided into groups as closely matched as possible in size and in distribution of the

^b Computed by the usual rule that the probable error of the difference of two means is the square root of the sum of the squares of their probable errors.

Fulmer, Nelson and Sherwood, This Journal, 43, 191 (1921).

⁸ Nelson, Fulmer and Cessna, J. Biol. Chem., 46, 77 (1921).

sexes, some groups receiving the skimmed milk powder unheated and others receiving heated milk powder as stated beyond. This skimmed milk powder was analyzed with the following results: moisture, 3.0; fat, 0.3; protein, 33.3; ash, 7.2; and carbohydrate by difference, 56.2%. It was fed mixed with the other food materials in a diet composed of starch, 50; skimmed milk powder, 40; purified butter fat, 9; and sodium chloride, 1%. Except for a different distribution of calories as between starch and fat, this diet corresponds fairly closely to the whole-milk-starch-fat diet which Osborne and Mendel have shown to be adequate.

Furthermore, unpublished experiments in this Laboratory have shown that 40% of the food mixture is about the minimum proportion of skimmed milk powder for optimum growth when this constitutes the sole source of protein and water-soluble vitamin and that when growth is retarded by further dilution of milk powder with starch, vitamin B becomes the first limiting factor in the growth of young rats. Hence, the use of 40% of skimmed milk powder in the food mixture for the experiments on growth of rats was considered analogous to the addition of 0.4 g. of this powder per 100 cc. of Williams' medium in the experiments upon the growth of yeast.

The experiments with rats were carried out in three series, (1) in the autumn of 1920, (2) in the summer of 1921, (3) in the autumn of 1921. In all cases the animals were weighed weekly and the feeding experiments continued for eight weeks. Using the diet described above, the gains in weight during the eight weeks, averaged for all the rats in each of the three series separately, with the probable errors of these averages, were as shown in Table II.

Table II

Gains in Weight of Rats during Eight Weeks on Experimental Diet Containing
Unheated Milk Powder

	No. of rats	Av. gain G.	Probable error
First series	11	125	± 4.0
Second series	39	92	± 2.2
Third series	14	99	± 2.9

Here it will be seen that averages of 11 to 39 animals in a series are subject to probable errors of about 2 to 3% of their numerical values. The differences in average gains from season to season are sufficient to emphasize the importance of making quantitative comparisons directly with control groups fed simultaneously rather than with pre-established normal rates of growth alone. The latter, however, are valuable as a check upon all work of this character.

The differences in general average gains between all animals receiving milk powder unheated, and all those receiving the same after heating are shown in Table III.

Table III

Gains in Weight of Rats during Eight Weeks on Diets with Unheated as

Compared with Heated Milk Powder

Time of heating milk powder at 100° Hours	No. of rats	G. A	v. gain Probable error	those	erence from on unheated ood Probable error	Food eaten G.
Unheated	64	100	± 2.0			537
6	28	86	± 2.7	14	± 3.4	513
12	23	77	± 1.8	23	± 2.7	501
24	21	59	± 2.5	41	± 3.4	439
48	22	40	± 3.3	60	± 3.9	406

Here it is plain that the differences in growth are too large to be accidental; but it is not plain whether the slower growth on the heated food is due to heat destruction of vitamin or to other causes. The last column of Table III shows that with increasing heat treatment of the food there was a progressive decrease in the amount of food consumed. The decreased food consumption would probably be sufficient to account for the decreased gain in weight whether heat destruction of vitamin had occurred or not. Since vitamin B promotes appetite it might be argued that decreased food intake is due to decreased vitamin content of the food through its heating; but the heating might make the food less appetizing in other ways, as through changing its flavor, and there is some reason to believe that this was actually a factor in these experiments because at the time they were made we had not entirely eliminated uneven heating, with consequent occasional local over-heating of the food. The thorough mixing, of the food would result in distributing through the whole food mixture any particles which might have acquired a cooked flavor through local over-heating. In subsequent experiments described in the paper which follows, the heat treatment was more perfectly controlled, the food consumption was more uniform and the differences in gains of weight attributable to dry heating of the food at 100° practically disappear.

When 10 animals on each variation of the heat treatment were compared with 10 litter-controls receiving unheated food, the average results were as shown in Table IV.

Table IV Comparisons of Gains and Probable Errors on Averages of Groups of Ten

Time of heating milk powder at 100° Hours	Av. gain G. Probable error	Decreased gain on heated food G. Probable error
Unheated	99 ± 3.6	
. 6	97 ±3.6	2 ± 5.1
Unheated	97 ±3.6	
12	86 ±2.4	11 ±4.3
Unheated	100 ±2.2	
24	56 ±3.6	44 ±4.2
Unheated	116 ±2.2	
48	51 ±4.9	65 ± 5.4

As explained above, these experiments do not answer the question as to whether the heat treatment here employed destroyed a measurable proportion of the vitamin. They do eliminate seasonal influences and illustrate well the degree of precision to be expected from this method when dealing with averages of groups of ten. The average gains in groups of 10 rats on unheated food are subject to probable errors of 2 to 4% while in those groups in which heating of food has decreased the average rate of gain the results are more variable and the probable errors are relatively larger.

Summary and Conclusions

The purpose of this work was to examine the availability of the gravimetric yeast-growth method and of the rat-growth method for quantitative study of vitamin B.

The gravimetric yeast-growth method using the Williams medium and procedure yielded consistent results. The coefficients of variation and the probable errors of the averages obtained in the different series were within limits quite satisfactory for work in this field, the probable errors being of the order of 1% of the observed numerical values. This method is, however, open to the objection that the increased growth of yeast which it measures may be due to the introduction of other substances favorable to yeast growth and is therefore not necessarily a measure of relative amounts of vitamin B. The medium devised by Fulmer, Nelson and Sherwood to overcome this objection did not, in our hands, prove adaptable to use with the gravimetric method of determining the growth of the yeast.

The rat-growth method also yielded quantitative results. It was found desirable to use rats four weeks of age for these experiments and to continue them upon the experimental diets for eight weeks. So far as is practicable each experimental animal should have a closely comparable control, taken at the same time from the same litter and of approximately the same initial size so that a series of comparisons can be made between animals confidently regarded as directly and accurately comparable. The conclusions reached through such comparisons should then be verified by comparison of the general averages of groups so large as to insure that individual peculiarities cannot appreciably affect the final result. In the work here recorded averages were drawn in each of these ways, and the probable errors of these averages were found to be of the order of 2 to 4% of their numerical values.

While the rat-growth method involves somewhat larger probable errors than the gravimetric yeast-growth method as here used, the results can be interpreted in terms of vitamin B with much greater certainty and we therefore consider the use of the growing rat to be the preferable method.

A CRITICAL INVESTIGATION AND AN APPLICATION OF THE RAT-GROWTH METHOD FOR THE STUDY OF VITAMIN B

By H. C. Sherman and Adelaide Spohn

Received August 6, 1923

For the present investigation white rats were selected as the experimental animal and dried skimmed milk as the vitamin-containing food. Our own experience and what we have been able to learn of the experience of others, lead to the belief that more regular results, and therefore a higher degree of precision in quantitative studies, may be expected from experiments with rats than with pigeons. While the gravimetric form of the Williams yeast-growth method is also capable of yielding satisfactorily quantitative data, the use of rats permits the interpretation of results in terms of vitamin B with much greater certainty and is therefore the preferable method.¹

Selection and Care of Experimental Animals.—The white rats used were placed upon the experimental diets when 28 or 29 days old, this being the standard age adopted in our Laboratory for the separation of young rats from their mothers. These young (four weeks old) rats weighed in all cases between 30 and 65 g., in most cases between 40 and 50 g. The animals all came from mothers on similar diets (a mixture of dried whole milk and ground whole wheat, with or without the addition of meat), with the further precaution that, in each experiment, equal numbers of comparison and control rats came from mothers on exactly the same diet.

The young rats were assigned to the diets to be compared in the following manner. If, for example, in one experiment there were five variations of diet to be compared and ten rats were to be fed on each variation, it would very likely be necessary to make use of six to eight litters to obtain the 50 rats required. Each litter was distributed over the five variations of diet as far as it would go so that each rat on each diet had litter-controls on other diets, and the entire 50 rats were so distributed in the assignment that the total weight of the ten rats and the number of males and females on each modification was practically the same. (At this age the difference in size between the sexes is much smaller than the individual variation in either sex.)

The experiments were continued for eight weeks, from the beginning of the fifth to the end of the twelfth week of the rat's life, this being the period during which the rat grows most rapidly if normally fed. It was demonstrated by continuing several of the experiments for a period of 50%

¹ Sherman and Edgeworth, This Journal, 45, 2712 (1923).

longer time that this extension of the experimental period beyond that here described did not yield any additional significant information.

In the (relatively few) experiments in which the milk was fed mixed with the rest of the diet, the animals were caged in lots of six to eight, each lot in a cage having a floor area of 28 by 35 cm. In all other experiments each rat was kept separately in a round galvanized iron wire cage 22.5 cm. in diameter and 20 cm. high with a raised screen floor which prevented access to the feces. No bedding was used nor was wood in any form accessible to the rats at any time. Fresh water and the basal ration were given freely. The cages were cleaned frequently, usually the group cages every day and the individual cages three times a week. The animals were weighed weekly (or oftener) and the amount of food consumed was determined and recorded for the same weekly intervals.

The Basal Diets.—The basal diets used were designed to be devoid of vitamin B and to contain all the other essential food factors in as nearly as possible the optimum proportions. No attempt was here made to supply vitamin C to the rats as they do not seem to need it and we do not know any source of vitamin C which could be depended upon to be entirely free from vitamin B. The two basal diets used in this work had the following composition.

Table I
Percentage Composition of Basal Diets

	Diet 94	Diet 107
Casein (purified by 60% alcohol) ^a	18	18
Salt mixture (Osborne and Mendel ²)	4	4
Butter fat	10	8
Cod liver oil	0	2
Starch	68	68
	100	100

^a The casein used in the basal rations was freed from vitamin B as follows. One liter of 60% (by weight) alcohol was poured upon 200 g. of casein and the mixture stirred for $^{1}/_{2}$ hour and then allowed to stand for $5^{1}/_{2}$ hours, filtered on a Büchner funnel and washed with 500 cc. of 60% alcohol; then again stirred with one liter of 60% alcohol as before, and this time the mixture was allowed to stand for 18 hours, then filtered and washed as before with 500 cc. of 60% alcohol and finally with 500 cc. of 90% alcohol to facilitate subsequent air-drying.

Tests of the Basal Diets.—In order to make sure that the basal diet contained the optimum amounts of its various constituents, it was fed in comparison with variations in which each ingredient in turn was increased in percentage, the increase replacing an equal weight of starch. Thus Diet 94 was compared with Diet 102 in which butter fat was increased to 15%; Diet 103, casein increased to 23%; Diet 105, salt

² Osborne and Mendel, J. Biol. Chem., 37, 572 (1919).

mixture increased to 5%; and Diet 104, casein replaced by meat protein. The results on these various diets were practically identical.

As a further test, similar variations in the constituents of the basal diet were introduced in experiments in which fixed amounts of milk were fed as sources of vitamin B. Again, no better results were obtained when the butter fat, or the casein, or the salt mixture was increased. Furthermore, it was shown by another series of experiments that the introduction of skimmed milk powder from which vitamin B had been extracted into the basal diet did not change the results. Each of the various modifications of both basal diets was tested on about 10 separate animals. Except for the condensed summary of a part of the data in Table III, the results of this extended and critical study of the basal diets are here omitted for the sake of economy of space. We believe it is amply established that the two basal diets used (Diets 94 and 107) furnish practically optimum amounts and proportions of all nutrients required by the rat except vitamin B, and that all increases in growth resulting from the addition of the milk to either of these diets may confidently be attributed to the vitamin B thus furnished.

The individual records of 10 rats receiving Diet 107 plus 8 cc. of milk per day are shown in Table II.

A series of comparative tests in which the same amount of milk was fed with different modifications of the basal diet yielded the average results shown in Table III.

Diet 108 differed from Diet 107 in containing 13% of butter fat; Diet 109 in containing 23% of casein; Diet 110 in containing 5% of the Osborne and Mendel salt mixture. It will be seen that the variability of the animals on the different diets was of the same order and that the gains on the different modifications of the basal diet were essentially the same, the differences being even smaller than their probable errors.

Table III Comparison of Basal Diets 107, 108, 109, 110 (Fed with 8 Cc. of Milk)

basal diets shown in Table I (above) were carried out for the purpose of finding the most advantageous amount of milk to feed in order to detect most readily any decrease in the vitamin B content which may result from

^b Computed according to the usual rule that the probable error of the difference of two means is the square root of the sum of the squares of their probable errors.

destruction by heat or from any other cause. The final average results of these two series of experiments are shown graphically in Parts 1 and 2, respectively, of Fig. 1. It will be seen from these curves that in the first series 8 cc. of milk per rat per day appeared to furnish an optimum amount of vitamin B, no further increase of growth resulting from larger feedings of milk. In the second series the rate of growth continued to increase with the amount of milk fed up to 12 cc. per rat per day, the largest amount here tested. The reason for this difference is not apparent; but in both cases it was found that the largest difference in weight gained from the same difference in milk fed is that between 6 cc. and 8 cc. per rat per day. Hence, for the purpose of the present investigation 8 cc. per rat per day was chosen as the best level at which to feed in order to detect any diminution in vitamin B content of the milk, since it is at this level that we found the largest difference in the total gain in weight for 8 weeks as compared with the next lower amount fed. (This presumably furnishes somewhat less than the optimum amount of vitamin B, since further addition of milk gave increased growth in many cases and in the general average; and it furnishes considerably more than the amount required for maintenance of constant weight which is the level of feeding found advantageous in some of our other experiments, as described in a subsequent paper.)

In another series of experiments the amount of milk given was varied in accordance with the weight of the rat, each animal receiving daily 5, 7.5, 10 or 12.5 mg. of the skimmed milk powder per gram of body weight. It was expected that this method might yield more regular results, but such did not prove to be the case. A comparison of the weight curves of the rats fed the same allowance of milk daily throughout the experiment, with those of rats whose daily allowance of milk was increased weekly in proportion to their increasing body weight, shows that the former are as uniform as the latter. Hence, in experiments in which the milk was fed separately from the basal ration we continued the method of giving each rat his predetermined daily dose regardless of changes in his body weight.

Since our plan contemplated experiments upon the heating of the milk in both the dry and the fluid condition, it seemed best for the sake of uniformity of conditions as affecting the experimental animals, to restore the dry milk to fluid form in all cases before feeding. This was done by mixing the weighed milk powder with distilled water in such proportions as to make 10 cc. of ("reconstructed") fluid milk from each gram of the skimmed milk powder. The daily dose of the fluid milk thus prepared was measured by means of a graduated pipet into a small feeding cup and placed in the cage at a uniform hour each day. Usually the rat consumed the daily allowance of milk promptly upon receiving it. When necessary in order to induce this, the water cup was removed until the milk had been consumed. This was necessary in only a few cases and then only for a

few feedings. In general there was no difficulty in securing prompt and complete consumption of the daily allowance of milk.

In several series of experiments the dry milk was fed mixed with the rest of the diet, replacing a smaller or larger part of the starch of Diet 94. The results are summarized graphically in Fig. 2, Part 1. The greatest

difference in rate of growth for a given increment of milk in the diet was found between the diet containing 20% and that containing 25% of the skimmed milk powder in the dry food mixture. Hence on the same principle that 8 cc. was selected as the daily feeding in the experiments described above, we here selected 25% as the proportion of milk powder to be included in the food mixture in the cases in which the effect of heating was to be tested by feeding the milk in admixture with the rest of the food. Table

IV shows the average numerical results obtained from 11 comparisons of the three diets, 99, 100 and 101, which contained 20, 25 and 30%, respectively, of the dry skimmed milk in place of equal weights of the starch contained in Diet 94.

Table IV

Comparison of Growth on Diets with Different Percentages of Skimmed Milk

Powder as Source of Vitamin B

a C 37	a . c H	-1-1- TIT					

^a See Note ^a of Table III.

The data summarized in Table IV illustrate well certain relationships usually found in vitamin experiments of this general type. Actual magnitude of the probable error of the average gain remains about the same as the gain increases with increased proportion of vitamin in the diet. Also the difference in gain in passing from diet to diet is considerably larger between 20 and 25, than between 25 and 30% of milk powder in the diet, yet the actual magnitude of the probable error of the two differences is about the same. The coefficient of variation is greatest for the diet containing (of those here compared) the smallest amount of vitamin and becomes less as the vitamin intake approaches the optimum. This is in accordance with the general experience of this Laboratory, that on diets permitting some growth but at a distinctly subnormal rate, individual variations are apt to be larger than on normal diet; and as the partially adequate diet is brought toward the optimum the rate of growth becomes both more rapid and more uniform. Certain observations in this Laboratory indicate further that as the diet is enriched in growth-promoting substances beyond the quantity or concentration required for optimum results individual variations again tend to increase, but we are not yet ready to generalize on this latter point.

The natural increase in total food intake with increasing rate of growth adds to the difficulty of interpreting growth rates quantitatively in terms of vitamin intake alone.

Effect of Heating at 100° upon Vitamin B in Milk in the Dry and Fluid States.—Dry heating was carried out by spreading the milk powder in a layer about 1 cm. deep in a flat-bottomed dish and heating in a constant-temperature oven, the temperature taken by means of a thermometer extending into the dry milk. When milk powder which had been heated for

^b See Note ^b of Table III.

^e "Coefficient of variation" = $\frac{\text{Standard Deviation}}{\text{Mean}} \times 100.$

6, 24 or 48 hours at 100° in the dry state, with free access of air, was substituted for the unheated dry milk, no effect of the heating could be detected, from the results as shown in Table V and in Fig. 2, Part 2.

TABLE V Comparison of Diets Containing 25 Per cent. of Skimmed Milk Powder, UNHEATED OR HEATED AT 100° Experiments with 15 rats

Time of heating of milk powder Hours	Average gai in weight in eight weeks G.	Probable error ^a	Difference from those receiving unheated milk G.	Probable errorb	Coefficient of variation in gainse	Average food intake G.
Unheated	84	± 5.0			34	520
6	88	± 5.0	4	± 7.1	33	511
24	87	± 3.0	3	± 5.8	20	506
48	82	± 4.2	2	± 6.5	29	455

For Notes a, b and c, see Tables III and IV.

Examination of the data in Table V shows plainly that the small differences in average gains on the heated and unheated milk powder are not significant; nor do the coefficients of variation or the data of food intake reveal any differences attributable to the heating of the milk. In view of the fact that the milk was the sole source of vitamin B and was fed at a level at which decrease of the vitamin B intake results in decrease of gain in weight, the results constitute strong evidence that the dry heating at 100° as here described caused no appreciable destruction of vitamin B. even when continued for 24 to 48 hours.

In another series of experiments the heated milk was fed separately from the basal diet, and in this series was also included the study of milk heated for 6 hours at 100° in fluid form, that is, in the presence of 9 to 10 parts by weight of water to 1 part of the skimmed milk solids. The results of the tests of the milk thus heated together with parallel tests on the same milk unheated and heated for 6 and 48 hours in the dry state are shown in Table VI. (Tests with milk heated dry for 24 hours were rejected because of accidental irregularities.)

TABLE VI Comparison of Tests with Milk as Source of Vitamin B, Unheated and Heated IN DRY OR IN FLUID FORM Experiments with 10 rats. Basal Diet 107.8 cc. of milk daily

Heat treat- ment of milk Hours at °C.	Average gain in weight in 8 weeks G.	Probable error ^a	Difference from that with un- heated milk G.	Probable error	Coeffi- cient of vari- ation of gains	Average food intake G.
Unheated	42	± 3.0	• •		33	283
6 100 (dry)	42	± 2.6	0	± 4.0	29	276
48 100 (dry)	37	±1.8	5	± 3.5	22	270
6 100 (wet)	6	± 1.6	36	±3.4	126	199

For Notes a, b and c, see Tables III and IV.

Here there was plainly no appreciable destruction of vitamin B in heating the milk powder dry for 6 hours at 100°, and probably no significant result when the same heating was continued for 48 hours. The animals receiving, as their sole source of vitamin B, the milk which had been heated 6 hours at 100°, wet, made distinctly lower average gains but showed much greater variability and a much lower average food intake. The average-weight curve for the rats receiving 8 cc. of milk thus heated approximates that of those receiving 6 cc. of unheated milk, so that if the difference due to heating the milk can be attributed wholly to destruction of vitamin B, the results would indicate a heat destruction of about $^{1}/_{4}$ of the vitamin B, as the result of heating for 6 hours in water at 100°. (The heating was carried out in thin-walled flasks immersed in briskly boiling water. A thermometer standing directly in the milk registered 99.5° to 99.8°.)

Thus there appears to have been an appreciable destruction in 6 hours' heating at 100° in water while there was no appreciable destruction in heating at 100° even up to 48 hours when the milk was heated in the dry state. Any seasonal differences in the growth of rats, and possible seasonal variations in the vitamin B content of milk, are eliminated here because all comparative tests were carried out simultaneously using milk powder from the same lot, and as previously explained the rats were all of exactly known age and relationship and were so distributed in the different tests that comparisons were nearly always with litter-controls.

Summary and Conclusions

A quantitative method for the determination of relative amounts of vitamin B by means of rat-growth experiments is described, and the known factors affecting the accuracy of the results of such experiments are discussed.

The data presented are representative of the work as a whole which comprised 11 series of experiments with a total of 38 variations of the experimental diet and included over 600 quantitative records of the food and growth of young rats.

The experiments were made upon rats of known age and relationship, the experimental period covering the fifth to the twelfth weeks of the rat's age, inclusive. It was found that the diet of the mothers from which the young rats are taken for experiment is a factor which must be kept uniform if results are to be as strictly quantitative as is possible.

Basal diets are described which are believed to be free from vitamin B and which are shown by numerous and rigorous tests to furnish practically optimum amounts of all other nutrients required by rats, the complete salt mixture of Osborne and Mendel being here considered as a unit.

The quantities of milk selected as most advantageous to feed in order to detect possible reduction in vitamin B content on heating were 0.8

g. of dry or 8 cc. of fluid skimmed milk per rat per day when fed separately from the basal ration, or 25% of the total food mixture when the skimmed milk powder was mixed with the basal diet.

By feeding the diets described to experimental animals of suitable age and size and sufficiently matched as to nutritional history and litter controls, it is believed to be possible, when dealing with averages of ten or more rats on each diet, to detect a diminution certainly of 25% and probably of 15% in the vitamin B content of the food tested.

There was no evidence of any measurable diminution of vitamin B in milk powder heated dry with free access of air at 100° even when this heating was continued for 48 hours. When the milk was heated in the fluid state for 6 hours at 100° there was an apparent diminution in its vitamin B content; probably about $^{1}/_{4}$ of the vitamin was thus destroyed. Vitamin B in the form in which it exists in milk is, therefore, comparatively stable to heating at 100° in the dry state, but less stable when heated at the same temperature in water solution.

NEW YORK, N. Y.

[Contribution from the Department of Chemistry, Columbia University, No. 425]

A QUANTITATIVE STUDY OF THE DESTRUCTION OF VITAMIN B BY HEAT

By H. C. Sherman and M. R. Grose Received August 6, 1923

In the study of vitamins the property of thermostability bears important relations both to the behavior of the vitamin in attempts to isolate it and to the conservation of the vitamin values of foods. Hence, statements regarding this property are frequently met, but most of the work which has been done to determine the effect of heating upon vitamins A and B has been qualitative, or little more than qualitative, in nature.

Building upon the work described in the two preceding papers^{1,2} we have attempted in the experiments here recorded to establish a quantitative relation between temperature and the rate of destruction by heat of vitamin B, somewhat as had been done in the previous work of this Laboratory with vitamin C.^{3,4}

Vitamin B is more stable than vitamin C both toward heat and toward oxidation but its destruction by heat can be studied on the same general principle by the use of higher temperatures. Using tests of the amounts of food required to cure polyneuritis in fowls or pigeons as the measure of

vitamin B content, Chick and Hume reported $^{5.67}$ results which have been widely quoted as indicating that vitamin B is stable at 100° but rapidly destroyed at temperatures around 120° . This would seem to imply, chemically, a marked increase in the temperature coefficient of the process of heat destruction in the neighborhood of 120° and, nutritionally, a marked diminution of vitamin B value in foods which have been subjected to the temperatures commonly used in processing canned goods as compared with those which have been heated only to the ordinary cooking temperature of about 100° . For both of these reasons and also because the behavior on heating constitutes an interesting point of comparison of vitamins with enzymes, the present investigation was undertaken with the general plan of determining the percentage destruction of vitamin B when heated in solution for four hours at 100° , 110° , 120° and 130° at the hydrogenion concentration equivalent to PH 4.3.

Methods and Materials Employed

For reasons explained in previous papers from this Laboratory^{1,2} we have employed the rat-growth method for the detection and measurement of any diminution of vitamin B which might result from destruction by heat. Young rats of an initial age of 4 weeks were used and the experimental period was continued for 8 weeks. The initial weights of individual rats were usually between 40 and 55 g. The precautions developed in the work of Sherman and Spohn² were observed in the selection of animals of sufficient uniformity and the arrangement of litter-controls. The same basal diet was also employed, namely, purified casein, 18%; butter fat, 8%; cod liver oil, 2%; Osborne and Mendel salt mixture, \$ 4%; starch, 68%. This basal diet was given freely, the food which furnished the vitamin B being always fed separately. All experimental animals were kept in individual cages having raised floors of wire screen so that the animals did not have access to their excreta. The construction and the frequent cleaning of the cages both served as precautions against the possibility of the animals obtaining any significant amount of vitamin from their own urine or feces. No bedding was used and the technique of the handling of the animals was as previously described.2

The juice of canned tomatoes was selected as the source of vitamin B in these experiments. Osborne and Mendel have shown⁹ that tomatoes are a rich source of vitamin B. There is every reason to suppose that canned tomatoes of a given brand will be fairly constant in this respect, and the use of this material makes the present work on vitamin B directly

comparable in all respects with our previous work on vitamin C.^{3,4} The canned tomatoes used in this study were all of the same brand. They were purchased as needed and in the course of the work the products of two seasons were used. We encountered no indication of material variation in the vitamin content of the canned tomatoes as purchased. In preparing the juice for feeding, either with or without heat treatment, the contents of the can was first thrown on cheese cloth and the juice separated from the bulk of the pulp by suction and pressure. The resulting juice was then passed through filter paper, yielding a light yellow liquid, clear or slightly opalescent, which yielded a slight coagulum when boiled, and a little carbonized material at 130°.

The heating at 100° was carried out in Erlenmeyer flasks immersed to the necks in a bath of boiling water heated by live steam. Loosely fitting glass stoppers with flanges that rested on the tops of the flasks rendered the evaporation negligible. Tests showed that such an arrangement gave a temperature within the flask about 0.2° lower than that of the boiling water without.

For the three higher temperatures a steam-heated autoclave was employed, the juice being contained in large Erlenmeyer flasks, closed with inverted beakers. For each heating the pressure was rapidly increased until the gage indicated that the desired temperature had been reached. The exhaust was then adjusted and the whole held at constant pressure for 4 hours, measured from the time of turning on the steam to the time of turning it off. The air was always blown out of the autoclave carefully in order that the pressure-temperature relation, as expressed on the gage, should not be in error. The accuracy of the temperature control was checked by readings of a thermometer inserted in the well of the autoclave. It was not difficult to regulate the autoclave so that the variations were not greater than 1° on either side of the desired temperature. Both the heated and the unheated portions of juice were consumed readily by the experimental animals. The "daily" doses were fed for six days each week.

A series of over 100 experiments, each involving the feeding of an experimental animal for eight weeks, was devoted to the quantitative determination of the relation between the amount of unheated tomato juice fed daily as sole source of vitamin B and the resulting gain or loss of weight during the experimental period of eight weeks. It was found that the most regular results were obtained at a level of vitamin intake which resulted in little or no net gain in body weight during the eight weeks of the experiment. This is usually 4 or 5 cc. of tomato juice per day depending upon the initial weight of the rat. The animals used in the series of experiments represented in Fig. 1 averaged somewhat larger than those used in the subsequent series. Because of the greater regularity of results in the region

of maintenance or of only slight gain, this was adopted as the basis of comparison to be used in the study of the effects of heating in this investigation, the experimental method thus differing slightly at this point from that employed in the preceding investigation.² In the main series of experiments to determine the effects of heating, 4 cc. per day of unheated juice was fed to the "positive control" animals, and different doses of the heated juices were fed to other animals from the same litter as the control to determine what amount of heated juice was equivalent in vitamin B content to 4 cc. of unheated juice.

Experimental Results

Unheated Tomato Juice.—Various quantities of unheated tomato juice up to 14 cc. were fed, but few experiments were made with more than 10 cc. as this was about as much as the animals would readily consume. The

larger amounts also tended to diminish the consumption of solid food, so that with quantities greater than 8 cc. the growth, although still below normal, did not increase in proportion to the increased vitamin intake. The average-weight curves of the rats receiving daily doses of 0, 2, 4, 5, 6, 7, 8, 9 and 10 cc. of unheated juice are shown in Fig. 1 and the average initial eight weeks of experimental feeding are given in Table I.

Heated Tomato Juice.-The effect of heating for and 130° was studied by means of feeding experi-

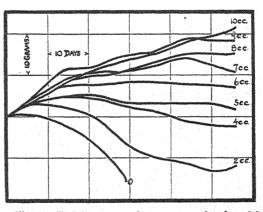

Fig. 1.-Weight curves of young rats showing the weights and total gain or effect of graduated doses of vitamin B in the form of loss in weight during the unheated tomato juice. Rats shown in curve marked O received the basal diet only, while those whose averages are shown by the other curves received this ration supplemented by daily doses of 2 cc. to 10 cc. of the unheated tomato juice as indicated on the curve. Table I shows the number and the average initial 4 hours at 100°, 110°, 120° weight and gain in weight of each group. The curves in this and following figures cover an experimental period of eight weeks

ments employing a total of about 50 animals for testing each temperature and varying the doses of the heated juices over a considerable range until the amount equivalent to 4 cc. (or to 5 or 6 cc.) of unheated juice had been approximated and then the experiment was repeated with doses at this level until averages establishing the equivalent quantities with sufficient precision were obtained.

logical variation from litter to litter is excluded as a source of error in the comparison of the average results.

In case a test animal died during the experimental period neither its record nor that of its direct control is included in the averages. Such premature deaths were somewhat more frequent among the rats getting the more highly heated juices but did not constitute an important factor in any case.

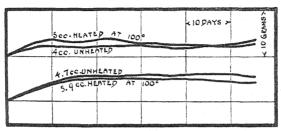

Fig. 2.—The upper curves show weights of rats receiving 4 cc. of unheated tomato juice in comparison with 5 cc. heated for 4 hours at 100°. The lower pair of curves represents the rats of Table II taken as a whole, and receiving an average dose of 4.7 cc. of unheated juice in comparison with 5.9 cc. heated for 4 hours at 100°

Of Tables II, III and V, each includes (1) a number of tests at a fixed ratio of dosage, (2) additional tests at varying ratios which latter are grouped together in the lower part of the table. Averages with or without these latter tests lead to the same conclusions. Feeling it somewhat safer in

It will be seen that throughout the four series of experiments summarized in Tables II to V, each experimental animal is paralleled by a litter control, and in each series the average initial weights of experimental and control animals are practically equal. This being the case, it has not seemed

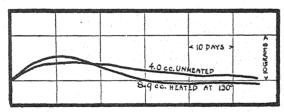

Fig. 5.—Weight curves of rats receiving 4 cc. of unheated tomato juice in comparison with those receiving an average dose of 8.9 cc. heated for 4 hours at 130°

essential to the purpose of this paper to discuss the relation of dosage to initial weights of individual experimental animals. From the data given this can easily be computed by any reader who desires to do so.

Discussion and Interpretation

The Percentage of Vitamin B Destroyed.—In each of the four tables given above the gain in weight of the animals receiving the heated juice is approximately the same as that of the positive controls. The curves of these sets of animals given in Figs. 2 to 5 further show that the two sets of animals closely parallel each other throughout the experimental period. It may, therefore, be concluded that the average doses of heated and unheated juice as given in each table are essentially equal in vitamin content. This being the case, the percentage of destruction by 4 hours' heating can be derived directly from the data of each table as follows.

Ce.	Temperature of heating °C.	Equivalent to unheated juice Cc.	Destruction
5.0	100	4.0	20
5.9	100	4.7	20
6.0	110	4.0	33
6.3	110	4.2	33
7.6	120	4.0	47
8.9	130	4.0	55

The data as obtained and employed in these tables are thought to involve a minimum of error, and the method of arriving at the percentage of destruction is both direct and simple.

In deriving the figures for destruction just given, the curves for the two sets of animals have been taken as substantially identical. If desired, one may compute them to coincidence in a comparatively simple manner, but it is open to question whether figures so obtained are of any higher order of precision.

To do this it is necessary only to compute the change required in the unheated doses to bring the two comparison curves into coincidence at the termination of the eight-weeks period. This is done by using the relation established between growth and unheated juice in the experiments summarized in Table I. The method of computing may be illustrated using the figures from the table for 100°. Here the positive controls give a curve terminating 1.2 g. (5.4–4.2) above that for the animals receiving heated juice; or, better, taking only those receiving doses of 4 as against 5 cc., the difference is 0.8 g. Since a difference of 1 g. in weight at the end of the eight weeks corresponds to about 0.25 cc. of unheated juice per day, the curves may be brought into coincidence by reducing the unheated dose of the positive controls from 4.7 to 4.4 cc. as against 5.9 cc., or better to 3.8 cc. against 5 cc., and the destruction at 100° becomes 24%. Carrying out similar computations for the averages of Tables IV and V gives indication of a destruction of 45% at 120° and 58% at 130°.

For destruction at 110°, the best data are probably those of the upper groups only in Table III which show exact agreement at 4 as compared with 6 cc. or a destruction of 33%.

Hence, according as we take the average data as they stand or the revised data resulting from the assumptions and calculations just explained, we obtain the two following series of estimates for heat destruction of vitamin B in 4 hours at the temperatures stated: at 100° , 20% or 24%; at 110° , 33%; at 120° , 47% or 45%; at 130° , 55% or 58%. The temperature coefficients computed for the three 10° intervals are:

```
Q_{10} (100-110^{\circ}) 33/20 = 1.6 \text{ or } 33/24 = 1.4
Q_{10} (110-120^{\circ}) 47/33 = 1.4 \text{ or } 45/33 = 1.3
Q_{10} (120-130^{\circ}) 55/47 = 1.2 \text{ or } 58/45 = 1.3
Q_{10} (Av. 100-130^{\circ}) 1.4 \text{ or } 1.33
```

Viewed from any standpoint the results plainly show that about $^{1}/_{5}$ to $^{1}/_{4}$ of the vitamin is destroyed by being heated for 4 hours at 100° in slightly acid medium and that (the other conditions remaining the same) about $^{1}/_{3}$ is destroyed at 110° , slightly less than $^{1}/_{2}$ at 120° , slightly more than $^{1}/_{2}$ at 130° . The temperature coefficient of the destructive process is distinctly lower than that of most chemical reactions, resembling in this respect that of vitamin C, and there is no rapid rise in the rate of destruction at temperatures around 120° as had been inferred from earlier work.

The low temperature coefficient of destruction by heat makes it improbable that the vitamin is an unstable protein, and inappropriate to group it with enzymes since the typical enzymes which have been studied in this respect have shown rates of destruction by heat with high temperature coefficients up to the point at which the enzymic activity was entirely destroyed.

Summary and Conclusions

The effect of 4 hours' heating upon vitamin B of tomato juice has been investigated at 10° intervals over the range of 100° to 130° using the growth of young rats during an experimental period of eight weeks as a measure of vitamin B content.

For this purpose a dosage giving approximate maintenance has been found to be the best level of feeding. The disturbing factors are thus minimized and the sensitivity of the method is apparently at a maximum.

The results show that when heated at a temperature of 100° for 4 hours in slightly acid medium there is an appreciable destruction of vitamin B, a fact in agreement with previous results obtained in this Laboratory, using milk in the liquid state as the source of vitamin B.

That this destruction is due to the effect of the hot water upon the vitamin, and not to the possible presence of dissolved air is indicated by the fact that much longer heating at 100° in the dry state with free access of air resulted in no appreciable destruction of vitamin B. (Experiments of Sherman and Spohn.)

The average figures for destruction of vitamin B in tomato juice, derived directly by determining the size of heated doses at each temperature necessary to give weight curves approximately coinciding with those of positive controls fed 4 cc. of unheated juice are for a period of 4 hours' heating, as follows: at 100°, 20%; at 110°, 33%; at 120°, 47%; at 130°; 55%.

By a further simple mathematical computation bringing the comparison curves into exact coincidence, the following slightly different figures have been obtained: at 100°, 24%; at 110°, 33%; at 120°, 45%; at 130°, 58%.

These figures establish a low temperature coefficient of heat destruction as one of the characteristics of vitamin B, a property possessed also by vitamin C as shown by the previous experiments of Delf and of LaMer,

Campbell and Sherman. For an increase of 10° in the temperature range of 100° to 130°, the rate of heat destruction of vitamin B in solutions such as here studied is increased only 1.3–1.4-fold, as compared with a 2-fold increase in most chemical reactions.

In the work here presented there was no indication of an increased temperature coefficient of heat destruction at temperatures around 120°. We find no evidence of any departure from the orderly course of a chemical reaction under the accelerating influence of heat but with a less than average temperature coefficient.

In this respect the heat destruction of the vitamin is in marked contrast with the heat coagulation of typical proteins and with the heat destruction of such typical enzymes as have been investigated.

As previously suggested in the case of vitamin C, the low temperature coefficient of the heat destruction of vitamin B may perhaps be due to the reaction being one which involves two phases of a heterogeneous system, the vitamin being in combination with or adsorbed upon colloidal material rather than in true solution in the hot water by which it is destroyed.

SYNTHESIS OF A NEW BICYCLIC NITROGEN RING. ISOGRANATANINE DERIVATIVES. PREPARATION OF AN ISOMER OF HOMOCOCAINE

By S. M. McElvain¹ with Roger Adams

RECEIVED AUGUST 9, 1923

Molecules containing bicyclic rings of an aliphatic character with a nitrogen atom in common occur in many of the natural alkaloids. Of these the most important are dihydro-nortropidine (I), quinuclidine (II), and granatanine (III), the basic nuclei of cocaine, quinine and pseudo-pelletierine respectively. The method described in this communication has been developed for the preparation of derivatives of a nucleus isomeric with granatanine, to which has been given the name isogranatanine (IV); a new ring resembling quinuclidine fairly closely.

¹ This communication is an abstract of a thesis submitted by S. M. McElvain in partial fulfilment of the requirements for the Degree of Doctor of Philosophy in Chemistry at the University of Illinois.

A nomenclature for the derivatives of this ring exactly analogous to that given granatanine compounds² has been adopted.

The syntheses of compounds containing rings of this character are very limited in number. Willstätter³ has prepared dihydro-nortropidine compounds in two ways, the first represented by the formation of bromotropane methyl ammonium bromide by heating δ -4-dimethylamino-cycloheptene bromide,

$$\begin{array}{c} N(CH_3)_2 \\ CH_2-\overset{!}{C}H-CH_2 \\ CH_2 \\ CH_2 \\ CH_2-CHBr-CHBr \end{array} \longrightarrow \begin{array}{c} CH_2-\overset{!}{C}H-\overset{!}{C}H_2 \\ (CH_3)_2NBr \\ CH_2-\overset{!}{C}H-\overset{!}{C}HBr \\ \end{array}$$

and the second by the formation of ethyl tropinone-carboxylate⁴ by an internal aceto-acetic ester condensation from pyrrolidine diacetic ester.

A study of quinine has led to a third method for the preparation of a bicyclic ring. This is illustrated by the formation of quininone⁵ by the action of alkali on N-bromoquinicine. In this reaction a 4-(β -keto-ethyl)piperidine, upon treatment with sodium hypobromite and alkali, gives first a 4-(β -keto-ethyl)piperidine-N-bromide which then loses hydrogen bromide to give a bicyclic ring, the hydrogen of the hydrogen bromide coming from the carbon atom adjacent to the ketone group.

$$\begin{array}{c|cccc} CH_2-CH-CH_2-CH_2COR & CH_2-CH-CH_2 \\ & CH_2 & & CH_2 \\ & CH_2 & & CH_2 \\ & CH_2 & & CH_2 \\ & CH_2 & & CH_2-N-CH-COR \\ \end{array}$$

Still another method has appeared, but it is doubtful whether it can be applied as generally as those methods illustrated by the examples just given. Robinson⁶ has prepared tropinone in 42% yields by the action of succinaldehyde, methyl amine and calcium acetone-dicarboxylate.

The method employed for the preparation of isogranatanine derivatives has involved an internal aceto-acetic ester condensation. Ethyl β -(3-

carbo-ethoxy-piperidino)propionate has been converted by means of sodium in xylene into ethyl isogranatonine-carboxylate.

With this substance available it is obvious that, by employing well-known reactions, isogranatanine and numerous other derivatives can be produced.

The general properties of ethyl isogranatonine-carboxylate are of interest. The free base is a colorless liquid, the hydrochloride a white solid. Both Ruzicka⁷ and Willstätter⁸ have studied amino β-ketonic esters of an analogous type and the latter has mentioned that they were thick oils which could not be purified because of the fact that even on standing in the cold they showed a tendency toward isomerization with the formation of a crystalline inner salt. This ketonic ester also is a thick oil which on standing in the cold gradually crystallizes. It has been found, however, that the ester can be purified if the proper conditions are used and it is probable that in a similar way the compounds made by these previous investigators could also be purified. The bath must be heated to considerably above the boiling point of the ester before the distilling flask containing it is immersed in the bath. In this way 60% of the original keto ester distils as a clear, colorless liquid while about 40% isomerizes or decomposes and remains behind in the flask. The distilled product is apparently perfectly stable and has been kept for several months without showing the slightest tendency to crystallize. The crystalline isomerization product can be readily obtained by dissolving the crude keto ester in ether and allowing the solution to stand; white crystals gradually deposit which have the solubility in organic solvents not of a base but of an ammonium compound. Undoubtedly an inner salt formation has taken place, as represented by Formula VII. The keto ester gives a characteristic coloration with ferric chloride, thus making it possible to distinguish it from its isomer, VIII, none of which, however, could be isolated from the reaction mixture.

8 Ref. 4, p. 30.

⁷ Ruzicka and others, Helvetica Chim. Acta, 3, 817 (1920); 5, 717 (1922).

The yields in this synthesis were low, as has also been true in all syntheses of similar types of compounds previously described. This is unquestionably due to the fact that the condensation may take place in several ways, especially with the formation of several types of dimolecular compounds. Moreover, unlike the compounds used for analogous internal condensations, which are symmetrical, the starting material in this reaction is unsymmetrical in nature. In spite of the low yields, a study of the ethyl isogranatonine carboxylate and its derivatives was rendered possible because of the ease with which the starting material, ethyl β -(3-carbo-ethoxy-piperidino) propionate, could be made in quantity. This latter substance (V) is produced from nicotinic acid (pyridine-3-carboxylic acid) which is readily formed by the oxidation of nicotine with nitric acid. Since nicotine is now a cheap commercial product, nicotinic acid is an easily available substance for the organic chemist. By means of a platinum oxide catalyst described recently,9 nicotinic acid hydrochloride may be readily reduced in comparatively large quantities to nipecotic acid hydrochloride, the hexahydro derivative. This reduced product is esterified to ethyl nipecotate and the latter condensed in the usual way with ethyl β -chloropropionate to give ethyl β -(3-carbo-ethoxy-piperidino) propionate.

The ethyl nipecotate was also condensed with ethyl chloro-acetate to give ethyl (3-carbo-ethoxy-piperidino)acetate. This latter substance did not condense with sodium to give a bicyclic ring.

The particular isogranatanine derivative of which a study has been made is the hydrochloride of ethyl benzoyl-isogranatoline-carboxylate (X) formed by the benzoylation of the hydrochloride of the alcohol, ethyl isogranatoline-carboxylate (IX), obtained by the reduction of the hydrochloride of ethyl isogranatonine-carboxylate (VI). This benzoyl derivative is very closely related to cocaine in structure.

During the past 25 years the importance of cocaine has led to a thorough study of synthetic substitutes. The important members of this latter class which have been discovered do not contain an alicyclic ring and are comparatively simple compounds. A study of substances more closely related to cocaine has been neglected on account of the difficulty of preparation and of the purely theoretical value of such information. It has been shown that slight changes in the structure of the cocaine molecule

⁹ Voorhees and Adams, This Journal, 44, 1397 (1922). Carothers and Adams, ibid., 45, 1071 (1923). Adams and Shriner, ibid., 45, 2171 (1923).

modify the therapeutic effect materially. This can be seen by a comparison of cocaine with α -cocaine¹⁰ (XI) and eccaine¹¹ (XII).

 α -Cocaine has no anesthetic action, whereas eccaine is a more powerful anesthetic than cocaine and is considerably less toxic. In the production of these two latter substances, basic changes in the bicyclic nucleus of cocaine have not been effected; the groups attached to the nucleus have merely been rearranged and changed. Until now, no attempt to find the effect of changes in the nature of the bicyclic ring has been made. In ethyl benzoyl-isogranatoline-carboxylate the ring containing the groupings essential to anesthesia in the bicyclic ring is left intact and the second ring is changed. The similarity between homococaine (XIII) and ethyl benzoyl-isogranatoline-carboxylate (X), and the change that has been effected, may be seen by writing the formula of the latter in a slightly different form (XIV).

The carbon atoms numbered 1, 2 and 3 in homococaine are still present in the new compound, but are attached in a slightly different manner.

The pharmacological action of ethyl-benzoyl-isogranatoline-carboxylate hydrochloride was kindly tested by Mr. Carl Nielsen of the Abbott Laboratories, Chicago, Illinois. It was found that if a 1% solution was injected intravenously into rabbits at the rate of 1 cc. in 18 seconds, the average toxicity was about twice that of cocaine hydrochloride. By a similar procedure, by injecting subcutaneously, the toxicity appeared to be about five times that of cocaine hydrochloride.

A 2% solution was applied to a rabbit's cornea. This, however, did not produce complete anesthesia. Moreover, the solution appeared to be distinctly more irritating than a similar solution of cocaine hydrochloride though it was only very faintly acid in reaction. There was no sign of dilation of the pupil, as is noticed with cocaine hydrochloride.

In regard to the formation of ethyl benzoyl-isogranatoline-carboxylate, it may be mentioned that the ethyl isogranatoline-carboxylate hydro-

¹⁹ Willstätter, Ber., 29, 2216 (1896).

¹¹ Von Braun, Ber., 51, 235 (1918).

chloride was formed by the catalytic reduction of the keto ester hydrochloride by means of platinum oxide as a catalyst. Willstätter¹² found that the reduction of an analogous keto ester was accomplished conveniently by means of sodium amalgam but the yields were very low. The results in this investigation showed that sodium amalgam could also be used but not only was the yield low, but two stereoisomers were formed simultaneously. No such complication occurred in the catalytic reduction; it required, however, a long period of time and a large amount of platinum. The product formed in this latter way was the same as one of the two isomers obtained by the sodium amalgam reduction. Benzoylation of the ethyl isogranatoline-carboxylate could not be accomplished by means of benzoic anhydride in toluene. It was effected by the action of benzoyl chloride upon the hydrochloride of the ethyl isogranatoline-carboxylate at a moderately high temperature.

Experimental Part 13

Nicotinic Acid Nitrate (Pyridine-3-carboxylic Acid Nitrate).—In a 5-liter round-bottom flask was placed 4 kg. of c. p. concd. nitric acid (d. 1.42). To this was added in 25cc. portions 210 g. of 95% nicotine. The addition was made carefully in order to prevent local heating and consequent loss of material. After each addition of nicotine the flask was shaken in order to insure a homogeneous solution. The addition of the nicotine caused the temperature of the liquid to rise somewhat but not sufficiently to cause evolution of oxides of nitrogen. The flask was then placed on a steam cone under a hood. As the liquid became warmed a vigorous reaction set in and sufficient heat was evolved to cause the liquid to boil. The boiling ceased after about 1 hour, but the flask was allowed to stand on the steam cone for 10 hours, during which time there was a more or less continuous evolution of oxides of nitrogen.

The contents of the flask were then poured into an evaporating dish and evaporated to dryness on the steam cone. The purification which follows was best carried out with the product of two such runs as described above.

The nicotinic acid nitrate from two runs, after evaporation of most of the liquid, was transferred to a 1.5-liter beaker, 400 cc. of distilled water was added, and the mixture heated until complete solution resulted. As this solution cooled, the nicotinic acid nitrate separated as yellowish crystals. It contained one molecule of water of crystallization and melted at 190–192°. By recrystallization from water with bone black, it could be obtained almost white. The yield was 430–460 g. No more of the nitrate could be obtained from the filtrate.

Nicotinic acid salts have been prepared by a number of methods of which only three are practical for making them in any quantity. Fischer¹⁴ prepared 3-cyanopyridine by the fusion of the corresponding sulfonic acid with sodium cyanide and then hydrolyzed this compound to nicotinic acid. The second method is by the decomposition of quinolinic acid.¹⁵ The third is by the oxidation of nicotine with nitric acid, ¹⁶ with potassium per-

manganate, " and with chromic acid. " Since nicotine is a commercial product of sold at a comparatively low cost, this latter method is by far the best process. The details given above allow for its production on a comparatively large scale with cheap reagents.

Nicotinic Acid Hydrochloride.—The nicotinic acid nitrate, which did not necessarily have to be dried, was placed in a 3-liter flask and 1000 cc. of coned. hydrochloric acid (d., 1.2) was added. This mixture was heated on a steam cone as long as gas evolution continued (6-8 hours). The flask was then connected to a condenser and the liquid removed under diminshed pressure (17-100 mm.). The dry salt thus obtained was covered with 500 cc. more of concd. hydrochloric acid (d., 1.2) and heated on a steam cone for about 5 hours longer. This was also distilled off in a vacuum and the dry salt remaining transferred to a 2-liter beaker and dissolved in 400 cc. of distilled water. Heating nearly to the boiling point was necessary to effect solution. The solution was diluted to about 4 times its original volume with 95% alcohol, placed in an ice-bath and stirred vigorously in order to form fine crystals. The precipitated hydrochloride was filtered and air-dried. It was white or cream colored and weighed 245 to 250 g. The filtrate was evaporated to dryness and the residue dissolved in the smallest possible amount of boiling water, diluted with alcohol and precipitated as described above. The precipitate was usually a light straw color and weighed 65 to 70 g. From the filtrate of this crystallization 10 to 15 g. of the hydrochloride was recovered. The total yield from two runs was 315 to 325 g. (80-83% yield); m. p., 273-274°. The material could be obtained pure and white by one recrystallization from water with bone black.

Nicotinic acid hydrochloride^{16,17} has previously always been prepared from nicotinic acid by neutralization with hydrochloric acid, a procedure much more tedious than the one just described.

Nicotinic Acid.—This was best prepared by dissolving 160 g. of the hydrochloride in 300 cc. of water and adding slowly a solution of 53 g. of anhydrous sodium carbonate in 150 cc. of water. Free nicotinic acid precipitated out and was filtered off. By concentrating the filtrate and allowing it to crystallize, more of the acid was obtained. Nicotinic acid was best recrystallized from hot water. The yield in this preparation was from 117 to 120 g. (95–98%); m. p., 230–232°.

Nicotinic acid has previously been made from the silver salt by precipitation with hydrogen sulfide^{16a} or from the copper salt by a similar procedure.^{16b} There is no difficulty in obtaining it directly from the salts by the action of sodium carbonate; in fact, it could undoubtedly be prepared from the nitrate instead of the hydrochloride. The reason why a method from the nitrate was not used was that the nitrate varies in composition as regards water of crystallization, thus complicating the calculation for the exact amount of alkali needed. The hydrochloride has no water of crystallization.

Ethyl Nicotinate.—A mixture of 50 g. of nicotinic acid, or 65 g. of nicotinic acid hydrochloride, with 200 g. of thionyl chloride was refluxed until complete solution took place (2 hours). The excess thionyl chloride was recovered by distillation from a steam cone and the last traces removed in a vacuum. The flask, containing the crystalline residue of the acid chloride hydrochloride, was again fitted with a reflux condenser and 100 cc. of absolute alcohol was added through the condenser. After refluxing this mixture for 1 hour the excess alcohol was removed under diminished pressure. The remaining crystals were covered with 150 cc. of benzene and 20% sodium carbonate solution

¹⁷ Laiblin, Ber., 10, 2136 (1877); Ann., 196, 135 (1879).

¹⁸ Huber, Ann., 141, 271 (1867); Ber., 3, 849 (1870).

¹⁹ The nicotine used in this investigation was purchased from the Hall Tobacco Company, St. Louis, Missouri. It was 95% pure but by one fractionation could readily be obtained practically 100% pure. The commercial material, however, was perfectly satisfactory for the oxidation with nitric acid.

was added until the aqueous layer was alkaline (about 135 cc.). The benzene layer was separated, the benzene removed, and the ethyl nicotinate distilled under diminished pressure; b. p., 103–105° (5 mm.); yield, 52–55 g., or 85–90%.

The esters of nicotinic acid have been prepared previously by the action of nicotinic acid, ²⁰ alcohol and hydrogen chloride, or nicotinic acid, alcohol and sulfuric acid. ²¹ It is mentioned in a paper on the preparation of acid chlorides of pyridine-carboxylic acids that the esters may be made by the action of alcohols on these compounds²² but no experimental details are given. This last procedure was found to be by far the most satisfactory for giving consistent results.

Nipecotic Acid Hydrochloride.—To a solution of 50 g. of nicotinic acid hydrochloride in 125 cc. of water was added 1 g. of platinum oxide catalyst, made from c. p. chloroplatinic acid²³ of commerce and the mixture was reduced under 1.5 atmospheres' pressure. The reduction was complete in 24 hours when one reactivation was made about 10 hours after the hydrogenation was started. The same catalyst was used over again, but it was advisable to add 0.25 g. of fresh platinum oxide with each subsequent reduction of 50 g. portions of nicotinic acid hydrochloride. In this way it was possible to reduce 300 g. of nicotinic acid hydrochloride with 2.25 g. of catalyst in approximately 6 days, when one reactivation with air²⁴ was made about 10 hours after the beginning of each reduction. After the catalyst was filtered off, the water was removed under diminished pressure. The yield was quantitative. After one recrystallization from alcohol the product melted at 240–242°.

The melting points which have previously been found by Ladenberg²⁵ and Freudenberg²⁵ are, respectively, 239–240° and 240–241°. These agree with the melting point obtained in this research, showing unquestionably that Hess²⁷ did not use nicotinic acid in his investigation.

Nipecotic acid hydrochloride has been previously prepared by the reduction of nicotinic acid with sodium and alcohol,²⁵ by the reduction of quinolinic acid with sodium and amyl alcohol²⁸ and by the catalytic reduction with platinum black.²⁶ The platinum oxide catalyst has proved to be much more active than any of those previously used and is to be recommended when large amounts of this product are desired.

Ethyl Nipecotate.—The aqueous solution of nipecotic acid hydrochloride representing the reduction of three 50 g. portions of nicotinic acid hydrochloride, was placed in a 3-liter flask and the water removed completely under diminished pressure. The dry residue was covered with 1200 cc. of a 5–6% solution of hydrogen chloride in absolute alcohol. The solution thus obtained was refluxed for 12 hours. The alcohol was then removed in a vacuum until 500–600 cc. of solution remained, the solution cooled to 0–5°, and 200 cc. of ether added. The liquid was transferred to a 2-liter separatory funnel and shaken vigorously with 150 cc. of 30% sodium hydroxide solution. The aqueous

²³ The chloroplatinic acid was the c. P. grade purchased from the Mallinckrodt Chemical Company, St. Louis, Mo.

²⁴ It is probable that if oxygen under pressure had been used for reactivation of the platinum catalyst, the time necessary for the reduction would have been reduced considerably. This work was completed before it was found that oxygen under pressure was very much more efficient than air in the reactivation.

²⁸ Bésthorn, Ber., 28, 3151 (1895).

alkaline layer was withdrawn, and extracted twice more with 200cc. portions of ether. The ether was removed from the combined ether extracts, thus leaving an alcoholic solution of the ester from which the alcohol was best removed under diminished pressure. The remaining ester was distilled under diminished pressure. The yield was 103–110 g. (70-75%) of product boiling at $102-104^{\circ}$ (7 mm.). The ester was a colorless water-soluble liquid; d_{20}^{20} , 1.0121; $n_{\rm D}^{19}$, 1.4592.

Analyses. Subs., 0.6421, 0.7116: 41.68 cc., 45.87 cc. of 0.0969 N HCl. Calc. for $C_8H_{18}O_2N$: N, 8.92. Found: 8.80, 8.75.

Ethyl Nipecotate Hydrochloride.—The hydrochloride was prepared by the addition of hydrogen chloride to an ether solution of the free base. The ether was poured off and the precipitate dissolved in as small a quantity of hot 95% alcohol as possible. To this solution ether was added until a faint cloudiness appeared, and the solution was then placed in an ice-bath. Ethyl nipecotate hydrochloride crystallized from the solution in needles which melted at 110–111°. This hydrochloride was stable to alkali carbonates.

Analyses. Subs., 0.1840, 0.2065: AgCl, 0.1358, 0.1525. Calc. for $C_8H_{16}O_2NCl$: Cl, 18.35. Found: 18.25, 18.26.

Ethyl nipecotate was also prepared by the catalytic reduction of ethyl nicotinate hydrochloride in alcoholic solution and by the reduction of ethyl nicotinate in alcohol containing 2 molecules of acetic acid. The yields were not nearly so satisfactory as in the above procedure.

$$\begin{array}{c|c} CH_2-CHCO_2C_2H_5\\ & | \\ \\ Ethyl \ \ (3-Carbo-ethoxy-piperidino) acetate, \\ CH_2 \ CH_2 \ .--A \ solution \ of \\ & | \\ CH_2-N-CH_2CO_2CH_5 \end{array}$$

 $100~\rm g.$ of ethyl nipecotate in $500~\rm cc.$ of 95% alcohol in a 1-liter flask was treated with $80~\rm g.$ of ethyl chloro-acetate. The solution on shaking became warm. To this was added $80~\rm g.$ of finely powdered silver oxide and the mixture shaken at frequent intervals until a test portion of the supernatant liquid, after acidification with nitric acid, gave no appreciable test for chloride with silver nitrate. This required from 6 to 8 hours. The contents of the flask were then heated to boiling on a steam cone in order to coagulate the silver chloride precipitate. This precipitate was filtered off by suction and washed once with $100~\rm cc.$ of warm alcohol, while stirred in a beaker. The alcohol from the combined filtrates was removed under diminished pressure and the remaining ester distilled. It boiled at $147-149°~(5~\rm mm.)$; d_{20}^{20} , 1.0684; n_{10}^{10} , 1.4607; yield $120-125~\rm g.$, or 80-83%. It was colorless when freshly distilled but on standing slowly acquired a pale yellow tinge. It was insoluble in water, and solutions of its mineral acid salts were decomposed by alkali carbonates.

Analyses. Subs., 1.1630, 1.2830: 48.85, 52.80 cc. of 0.0969 N HCl. Calc. for $C_{19}H_{21}O_4N$: N, 5.76. Found: 5.71, 5.60.

Attempts were made to condense this ester into a bicyclic system by the use of sodium ethylate in benzene, and sodium in toluene, xylene and cymene. However, the ring formation could not be effected with any of these reagents and it was possible to recover from 60-80% of the unchanged diester from each attempted condensation.

ETHOXY-PIPERIDINO) ACETATE.—A mixture of 5 g. of ethyl (3-carbo-ethoxy piperidino)-acetate, 10 g. of barium hydroxide and 250 cc. of water was refluxed for 2 hours in a 500cc. Hask. The excess barium was removed from the hot solution by carbon dioxide and

filtration. To the filtrate was added dil. sulfuric acid until the remaining barium was just completely precipitated. This precipitate was filtered and to the resulting filtrate 10 g. of copper oxide powder was added. After the mixture had been refluxed for 1 hour and filtered, a deep blue solution of the copper salt of the acid was obtained. This solution was concentrated to a volume of about 25 cc. and allowed to cool. The copper salt of the acid crystallized in deep blue crystals. These were dissolved in 100 cc. of hot water and the copper was precipitated by hydrogen sulfide. The precipitated sulfide was removed by filtration and the filtrate evaporated to dryness on a steam cone. The residue after recrystallization from an alcohol-ether mixture formed white crystals and melted at 268–270° (with decomp.); yield, 2.5 g., or 65%.

From Nipecotic Acid Hydrochloride.—A mixture of 10 g. of nipecotic acid hydrochloride, 7 g. of chloro-acetic acid and 13 g. of sodium hydroxide was dissolved in 250 cc. of water and the solution stirred for 3 hours. Hydrochloric acid was then added until the reaction was acid to congo red and the solution evaporated to dryness under diminished pressure. The residue was treated with 200 cc. of hot 95% alcohol and the sodium chloride remaining was removed by filtration. From the filtrate the alcohol was removed under diminished pressure, leaving a yellowish amorphous residue. From this residue, the dibasic acid was isolated through the copper salt as described above; yield, 3.5–4.5 g., or 31–40%. This acid was identical with the one obtained by the hydrolysis of ethyl (3-carbo-ethoxy-piperidino)acetate.

Analyses. Subs., 0.7432, 0.6918: 40.35, 36.85 cc. of 0.0969 N HCl. Calc. for $C_8H_{18}O_4N$: N, 7.48. Found: 7.35, 7.22.

Ethyl (3-Carbo-ethoxy-piperidino)propionate (V). From Ethyl, Nipecotate,—A solution of 100 g, of ethyl nipecotate in 500 cc. of 95% alcohol was mixed with 90 g, of ethyl chloropropionate in a 1-liter round-bottom flask. The remainder of the procedure was exactly the same as that described for the preparation of the ethyl (3-carbo-ethoxy-piperidino)acetate. The product was a colorless, water-insoluble oil, boiling at 159–161° (5 mm.); $d_{\rm 20}^{20}$, 1.0452; $n_{\rm D}^{13}$, 1.4605; yield, 126-135 g., or 78-83%. As in the case of its lower homolog, aqueous solutions of its mineral acid salts were decomposed by alkali carbonates.

Analyses. Subs., 0.9790, 1.1891: 38.05, 46.93 cc. of 0.0969 N HCl. Calc. for $C_{18}H_{29}O_4N$: N, 5.45. Found: 5.29, 5.36.

From Nipecotic Acid Hydrochloride.—A mixture of 50 g. of nipecotic acid hydrochloride, 50 g. of β -chloropropionic acid and 65 g. of sodium hydroxide in 500 cc. of water was stirred for 3 hours at room temperature. After this time hydrochloric acid was added until the reaction was acid to congo red. The water was then removed from the solution under diminished pressure and the resultant salt residue treated with 500 cc. of hot 95% alcohol. The solution was filtered from the sodium chloride, placed in a 1-liter flask and evaporated to complete dryness under diminished pressure. The residue was esterified and the ester recovered by the same method as that described for the preparation of ethyl nipecotate from nipecotic acid hydrochloride; yield, 20–28 g., or 25–35%; b. p., 157–162° (5 mm.).

Ethyl Isogranatonine-carboxylate Hydrochloride (VI).—A mixture of 10 g. of freshly cut sodium and 100 cc. of xylene was placed in a 500cc. flask fitted with a ground-glass reflux condenser. The sodium was finely powdered by first heating it in the xylene to boiling and then stoppering the flask and shaking vigorously. To the xylene-sodium mixture was then added 100 g. of ethyl- β -(3-carbo-ethoxy-piperidino)propionate and the mixture heated in an oil-bath. When the liquid inside the flask reached a temperature of about 130° a vigorous reaction set in with the liberation of sufficient heat to cause the xylene to boil for 15–20 minutes. The temperature of the oil-bath was maintained between 140–150° for about 45 minutes after the primary reaction had ceased. This was

necessary in order to obtain maximum yields. The end of the reaction was shown by an excessive foaming of the contents of the flask. The flask was then cooled, whereupon the contents turned to a semi-solid mass. This product was then mixed with 150–200 cc. of ice water, and the xylene layer separated. The aqueous layer was extracted with 150 cc. of ether and this extract added to the xylene layer. This ether-xylene solution will be referred to later.

The aqueous solution obtained above was dark red in color. It was kept at a temperature of 0–5° and acidified with hydrochloric acid until acid to congo red. Upon acidification the color of the solution changed from a dark red to a light yellow. To the cold acid solution, potassium carbonate was added until it was distinctly alkaline, and the resulting alkaline solution was extracted with 150cc. portions of ether until test portions of the ether, when shaken with a dil. acidified aqueous solution of ferric chloride, caused no pronounced reddish purple coloration of the aqueous layer. The ether extracts (usually four) were concentrated to a volume of about 100 cc. and dry hydrogen chloride was passed in. The hydrochloride of the keto ester precipitated usually in an amorphous form.

The amorphous keto ester hydrochloride was crystallized by the following procedure. The material from the ether precipitation was dissolved in 15 cc. of warm absolute alcohol. To this solution dry ether was added until a faint cloudiness appeared, at which point the solution was cooled to about —12°. By scratching the sides of the container with a stirring rod, crystallization was started. Ethyl isogranatonine-carboxylate hydrochloride crystallized as white microscopic crystals which melted at 187–189°. It was extremely soluble in water, 95% alcohol and absolute alcohol. Only a trace of it added to a dil. ferric chloride solution gave a deep reddish-purple coloration. The yield of recrystallized material from the above run was 5.5–6.5 g. or 6–7%. From 1 to 1.5 g. of uncrystallizable material remained in the mother liquors.

Analyses. Subs., 0.1035, 0.1465: AgCl, 0.0590, 0.0850. Calc. for C₁₁H₁₈O₅NCl: Cl, 14.34. Found: 14.12, 14.34.

Internal condensations of this diester were attempted also with sodium ethylate in benzene and sodium in toluene and cymene. At the temperatures obtained with benzene and toluene the ester was left practically unchanged. Sodium in cymene, however, did completely condense the ester, but the products were of high molecular weight and it was not possible to isolate any of the cyclic keto ester by the procedure used in isolating it from the sodium-xylene condensation.

Ethyl Isogranatonine-carboxylate (VI).—A mixture of 4 g. of ethyl isogranatonine-carboxylate hydrochloride and 10 cc. of saturated potassium carbonate solution was shaken and then extracted twice with 20cc. portions of ether. The ether layer was separated and the ether then distilled. The remaining ester was placed in a small distilling system and the system evacuated to a pressure of 8 mm. The distilling flask was then immersed directly in an oil-bath at a temperature of 150–160°. The keto ester distilled at 137–139° (8 mm.); d_{20}^{20} , 1.1381; n_{1}^{18} , 1.5070; yield, 2.2 g., or 60%. It was a thick, colorless oil, insoluble in water, soluble in acid and alkali, and gave a pronounced coloration with acidified ferric chloride solution. The remainder of the ester was left in the distilling flask, probably partly as an inner salt (VII).

Analyses. Subs., 0.7185, 0.6905: 34.60, 33.40 cc. of 0.0969 N HCl. Calc. for $C_{11}H_{17}O_{1}N$: N, 6.63. Found: 6.55, 6.57.

When the crude ethyl isogranatonine-carboxylate obtained as described above by the evaporation of the ether was redissolved in ether and allowed to stand, white hygroscopic crystals separated in 12 to 24 hours. These were insoluble in ether. By acidifying with hydrochloric acid and repeating the process described above the oily isomer was again obtained.

An attempt was made to prove the presence of the isomeric ketonic ester (VIII) in the xylene-ether layer. This layer from condensations representing 400 g. of ethyl β -(3-carbo-ethoxy-piperidino)propionate was extracted with hydrochloric acid. The hydrochloric acid layer was made alkaline with potassium carbonate and extracted with ether. After evaporation of the ether 15 g. of an oil was obtained. This was refluxed with 150 cc. of 20% hydrochloric acid for 4 hours in order to hydrolyze it to the corresponding amino ketone. No product, however, was obtained.

Ethyl Isogranatoline-carboxylate Hydrochloride (IX). REDUCTION WITH SODIUM AMALGAM.—A solution of 5 g. of ethyl isogranatonine-carboxylate hydrochloride in 1 liter of 5% hydrochloric acid was placed in a 20cm. evaporating dish. Sodium amalgam (3%) was added in small pieces at a rate sufficient to maintain a vigorous evolution of gas. At the same time the temperature of the solution was kept below 20° by an external ice-bath and the reaction of the solution was kept acid to congo red by the addition of 50cc. portions of concd. hydrochloric acid when the solution appeared alkaline to the indicator. About 1500 g. of 3% sodium amalgam, added during 5 hours, was required to complete the reduction, the end of which was shown by a negative ferric chloride test. When this point was reached the mercury was separated and the aqueous layer filtered. The colorless aqueous solution was evaporated to dryness under diminished pressure and the resulting salt residue treated with two successive 300cc. portions of hot 95% alcohol. The resulting alcoholic solution, after removal of the sodium chloride, was evaporated to complete dryness under diminished pressure. The straw-colored, amorphous residue was covered with 500 cc. of 5-6% alcoholic hydrochloric acid and esterified by refluxing for 12 hours. The alcoholic hydrochloric acid was removed under diminished pressure and the residue was treated with 25 cc. of saturated potassium carbonate solution, then extracted with ether. The ether extract was concentrated to a volume of 100 cc. and dry hydrogen chloride was passed in. The hydrochloride of the base precipitated as a brown amorphous mass.

This amorphous material was crystallized as was the ethyl isogranatonine-carboxylate hydrochloride. The first crystallization yielded a light brown material which after three crystallizations appeared as practically colorless, microscopic crystals which melted at 199–201° (Isomer A); yield, 0.35 g., or 7%.

Analyses. Subs., 0.0810, 0.0800: AgCl, 0.0465, 0.0454. Calc. for $C_{11}H_{20}O_2NCl$: Cl, 14.23. Found: 14.20, 14.05.

From the mother liquors of the crystallization described it was impossible to obtain any more crystalline material, so they were combined, evaporated and the free base was liberated into ether by means of a saturated potassium carbonate solution. The ether was removed from the extract and the remaining oil subjected to distillation at 5 mm. pressure. It was dissolved in dry ether and the hydrochloride prepared and crystallized. After one crystallization the product melted at $199-201^{\circ}$. A mixed melting point with the crystals (Isomer A) obtained as described above was $170-175^{\circ}$. This product was Isomer B and the yield was 0.450 g., or 9%. There remained in the mother liquors of B 0.6 g. of uncrystallizable material.

Analyses. Subs., 0.1047, 0.1022: AgCl, 0.0589, 0.0581. Calc. for $C_{11}H_{20}O_{3}NCI$: Cl, 14.23. Found: 13.95, 14.10.

CATALYTIC REDUCTION.—A solution of 4 g. of ethyl isogranatonine-carboxylate hydrochloride in 50 cc. of absolute alcohol was shaken with hydrogen at 4 atmospheres' pressure in the presence of 2 g. of platinum oxide catalyst. Every 12 hours the catalyst was shaken with air and at 24-hour intervals 0.5 g. of fresh catalyst was added. The reduction was complete, as shown by a negative ferric chloride test, in 85 hours. The platinum was filtered off and the solution evaporated to dryness under diminished pressure.

The residue on recrystallization gave 2.5 g. (62.5%) of a product which was identical with Isomer B from the sodium amalgam reduction.

Ethyl Benzoyl-isogranatoline-carboxylate Hydrochloride (X). Benzoyl Chloride Benzoyl Chloride Benzoyl Chloride. In a 100cc. flask fitted with a ground-glass reflux condenser was placed 3 g. of ethyl isogranatoline-carboxylate hydrochloride (Isomer B) and 10 cc. of freshly distilled benzoyl chloride. The flask was then heated in an oil-bath to 140–160°. At this temperature a vigorous evolution of hydrogen chloride took place and in 20 minutes the reaction was complete. The resulting solution was cooled and diluted with 75 cc. of ether. The hydrochloride of the benzoyl derivative precipitated as a light brown, amorphous mass. The ether solution was poured off and the precipitate dissolved in 20 cc. of warm absolute alcohol. This solution was heated with 0.1 g. of bone black and filtered. From the filtrate the hydrochloride of the benzoyl derivative was obtained in pure white crystals by a method analogous to that described for ethyl isogranatonine-carboxylate hydrochloride; yield, 3.4 g., or 80%.

Analyses. Subs., 0.1044, 0.1058: AgCl, 0.0415, 0.0429. Subs., 0.4760: 13.51 cc. of 0.0951 N HCl. Subs., 0.2030: CO₂, 0.4523; H₂O, 0.1280. Calc. for $C_{18}H_{24}O_4NCl$: C, 61.07; H, 6.84; N, 3.96; Cl, 10.03. Found: C, 60.77; H, 7.00; N, 3.78; Cl, 9.84, 10.03.

An attempt was made to obtain this benzoylation product by the action of benzoic anhydride in toluene upon ethyl isogranatoline-carboxylate, obtained from the hydrochloride by the action of saturated potassium carbonate. No benzoylation product was obtained.

Summary

- 1. A method for the preparation of a derivative of a new bicyclic nucleus containing a nitrogen atom common to both rings has been developed. The new nucleus has been called isogranatanine because it is isomeric with granatanine.
- 2. The particular derivative especially investigated was ethyl benzoylisogranatoline-carboxylate, prepared by reduction of the ethyl isogranatonine-carboxylate and subsequent benzoylation.
- 3. The ethyl benzoyl-isogranatoline-carboxylate hydrochloride is isomeric with homococaine hydrochloride, and is a local anesthetic. It is considerably more toxic and less anesthetic than cocaine. Its 2% solution is irritating to a rabbit's cornea and does not cause dilation.

ARSENATED N-ARYLAMINO ALCOHOLS1

By Cliff S. Hamilton Received August 9, 1923

The action of ethylene chlorohydrin on aromatic amines was first studied by Knorr.² He found that when equivalent amounts of aniline and ethylene chlorohydrin were heated together in a closed tube at 110° for one hour, 2-anilino-ethanol was the chief product. More recently Rindfusz and Harnack³ have shown that N-arylamino alcohols can be prepared by boiling aniline with ethylene chlorohydrin or with trimethylene chlorohydrin in the presence of sodium carbonate.

This investigation was undertaken in order to study the action of chlorohydrins on aromatic arsonic acids, containing an amino group in the ring. The condensation took place in the case of p-arsanilic acid. With m-arsanilic acid, 3-amino-4-methyl-phenylarsonic acid and 3-amino-4-hydroxy-phenylarsonic acid,—that is, compounds containing the amino group in the meta position with respect to the arsenic,—negative results were obtained.

The arsonated N-arylamino alcohols were prepared by heating the amino-aryl arsonic acid, dissolved in sodium hydroxide solution, with an excess of the chlorohydrin. They are beautiful crystalline compounds and have definite melting points. By dissolving the arsonic acids in the calculated amount of 2N sodium hydroxide solution and filtering into alcohol, sodium salts were obtained as colorless crystalline compounds, containing various amounts of water of hydration, depending upon the concentration of the alcohol used. Treatment of the arsonated N-arylamino alcohols with sodium hydrosulfite gave the yellow, highly insoluble arseno compounds.

Pharmacological experiments have been carried out with the monosodium salt of 2-p-arsono-anilino-ethanol and 3-p-arsono-anilino-propanol. As was expected, the latter, having the longer side chain, was the more toxic. From preliminary experiments, 3-p-arsono-anilino-propanol appears to have the higher trypanocidal action.

Experimental Part

Preparation of Arsono Compounds

One molecular equivalent of the amino-aryl arsonic acid was dissolved in the calculated amount of N sodium hydroxide solution to form a mono-sodium salt; 1.5 molecular equivalents of the chlorohydrin was then added

- ¹ This work was made possible by a grant from the Public Health Institute, Chicago. Some of the products are being studied pharmacologically in this Laboratory under the direction of Dr. A. S. Loevenhart.
 - ² Knorr, Ber., 22, 2092 (1889).
 - ³ Rindfusz and Harnack, This Journal, 42, 1720 (1920).

and the mixture boiled under a reflux condenser for 4 to 5 hours. The solution deposited almost colorless crystals on cooling. Concd. hydrochloric acid was added to the cold mixture to hold any unchanged p-arsanilic acid in solution and the product was filtered off and washed carefully with water. It was purified by recrystallization from hot water.

2-p-Arsono-anilino-ethanol, CH₂OHCH₂NHC₆H₄AsO₈H₂.—This compound prepared from p-arsanilic acid and ethylene chlorohydrin was obtained in 35-40% yields. The colorless needles, which melt at 167-168° (uncorr.), are soluble in hot water and dil. alkalies, but are insoluble in ether and benzene.

Analyses. Subs., 0.1989, 0.1994: 32.40, 32.60 cc. of 0.0464 N iodine soln. Subs., 0.4011, 0.4005: 14.95, 15.05 cc. of 0.1 N HCl soln. Calc. for $C_8H_{12}O_4NAs$: N, 5.36; As, 28.73. Found: N, 5.22, 5.26; As, 28.37, 28.47.

Monosodium Salt.—Ten g. of 2-p-arsono-anilino-ethanol was dissolved in 19 cc. of 2 N sodium hydroxide solution and the solution was filtered in a fine stream into 95% alcohol. Colorless crystals were deposited immediately. The yield was almost quantitative.

Analyses. Sample dried at 105°. Subs., 0.1992, 0.1998: 30.20, 30.35 cc. of 0.0464 N iodine soln. Subs., 0.4001, 0.3992: 14.50, 14.20 cc. of 0.1 N HCl. Calc. for $C_8H_{11}O_4$ -NAsNa; N, 4.94; As, 26.50. Found: N, 5.07, 4.98; As, 26.41, 26.46.

Mono-ammonium Salt.—Using ammonium hydroxide in place of sodium hydroxide solution, this compound was prepared by the method outlined under the sodium salt, as colorless needles, readily soluble in cold water.

Analyses. Sample dried at 105°. Subs., 0.1991, 0.2003: 32.40, 32.70 cc. of 0.0436 N iodine soln. Subs., 0.3012, 0.2996: 21.42, 21.38 cc. of 0.1 N HCl. Calc. for C_8H_{14} - O_4N_2As : N, 10.07; As, 26.97. Found: N, 9.96, 9.99; As, 26.65, 26.74.

Barium Salt.—This compound was prepared by dissolving the arsonic acid in hot water and adding the calculated amount of a barium hydroxide solution. A white precipitate formed on standing that was insoluble in alcohol, but somewhat soluble in water.

Analyses. Sample dried at 105°. Subs., 0.2002, 0.1999: 27.10, 27.50 cc. of 0.0436 N iodine soln. Calc. for $C_{16}H_{22}O_{8}N_{2}As_{2}Ba$: As, 22.88. Found: 22.17, 22.53.

3-p-Arsono-anilino-propanol, CH₂OH(CH₂)₂NHC₅H₄HsO₅H₂.—Following the general procedure for the preparation of arsono compounds, 21.7 g. of p-arsanilic acid when treated with 14 g. of trimethylene chlorohydrin, gave 8 g. of product. Recrystallization from hot water gave colorless crystals; m. p., 160–161° (uncorr.).

Analyses. Subs., 0.2016, 0.2004: 32.50, 32.40 cc. of 0.0452 N iodine soln. Subs., 0.4052, 0.4041: 14.30, 14.42 cc. of 0.1 N HCl. Calc. for C₂H₁₄O₄NAs: N, 5.09; As, 27.27. Found: N, 4.94, 4.99; As, 27.42, 27.40.

SODIUM SALT.—Four g. of the corresponding arsonic acid gave 3.9 g. of the sodium salt as colorless crystals from 95% alcohol, on standing.

Analyses. Subs. (dried in oven at 105°), 0.1987, 0.1991: 30.60, 30.60 cc. of 0.0443 N iodine soln. Subs., 0.3991, 0.3980: 13.61, 13.52 cc. of 0.1 N HCl. Calc. for C₂H₁₈-O₄NAsNa: As, 25.25; N, 4.71. Found: N, 4.77, 4.75; As, 25.60, 25.55.

AMMONIUM SALT.—By dissolving the arsonic acid in ammonium hydroxide and filtering the solution into alcohol, colorless needles were obtained in good yields.

Analyses. Subs. (dried in oven at 105°), 0.1898, 0.1901: 30.00, 29.90 cc. of 0.0436 N iodine soln. Subs., 0.3008, 0.3006: 20.48, 20.51 cc. of 0.1 N HCl. Calc. for C₉H₁₆O₄-N₂As: N, 958; As, 25.68. Found: N, 9.54, 9.55; As, 25.89, 25.76.

BARIUM SALT.—A white powder, prepared as was the barium salt of 2-p-arsono-anilino-ethanol, was obtained.

Analyses. Subs. (dried in oven at 105°), 0.2017, 0.2003: 26.40, 26.20 cc. of 0.0436 N iodine soln. Calc. for $C_{17}H_{24}O_8N_2A_{52}Ba$: As, 21.89. Found: 21.43, 21.42.

Preparation of Arseno Compounds⁴

One molecular equivalent of the arsonated N-arylamino alcohol was dissolved in hot water. This solution was added with shaking to a solution of 10 equivalents of sodium hydrosulfite in 550 equivalents of water, after the latter solution had been previously treated successively with 6 equivalents of 10 N sodium hydroxide solution and 10 equivalents of crystalline magnesium chloride and filtered from the magnesium hydroxide formed. After this mixture had been heated on a water-bath and frequently shaken for $^{1}/_{2}$ hour, the yellow precipitate which formed was filtered off, washed with water, alcohol, and ether and dried in a vacuum.

2-p-Arseno-anilino-ethanol, CH₂OHCH₂NHC₆H₄As=AsC₆H₄NHCH₂CH₂OH.— Five g. of 2-p-arsono-anilino-ethanol upon reduction, as outlined above, gave a 30% yield of the yellow arseno compound. It is insoluble in common organic solvents and does not melt below 250°.

Analyses. Subs., 0.1779, 0.1783: 38.70, 38.60 cc. of 0.0440 N iodine soln. Calc. for $C_{16}H_{20}O_2N_2As_2$: As, 35.57. Found: 35.93, 35.77.

3-p-Arseno-anilino-propanol, CH₂OH(CH₂)₂NHC₆H₄As=AsC₅H₄NH(CH₂)₂CH₂-OH.—The reduction of 10 g. of 3-p-arsono-anilino-ethanol gave 4.5 g. of the arseno product. It does not melt below 250° and has the usual properties of arseno derivatives. Analyses. Subs., 0.1984, 0.1990: 39.80, 39.90 cc. of 0.0440 N iodine soln. Calc. for C₁₅H₂₄O₂N₂As₂: As, 33.33. Found: 33.14, 33.12.

Arsonated s-Di-anilino Ethane

s-Bis(p-arsono-anilino) ethane, $H_2O_2AsC_6H_4NH(CH_2)_2NHC_6H_4AsO_2H_2$.—To a solution of 21.7 g. of p-arsanilic acid in 100 cc. of N sodium hydroxide solution was added 12 g. of ethylene dibromide and the mixture was boiled under a reflux condenser. The ethylene dibromide gradually dissolved, and a white solid began to form. After the mixture had been boiled for two hours, it was cooled, 10 cc. of concd. hydrochloric acid was added to hold the unchanged arsanilic acid in solution, and the product was separated by filtration. It was purified by dissolving it in 10% sodium hydroxide solution, filtering and acidifying the filtrate with concd. hydrochloric acid; yield, 7 g.

The product is readily soluble in dil. alkalies, two molecular equivalents of sodium hydroxide being required for the neutral salt. It does not melt below 250°.

Analyses. Subs., 0.1888, 0.1992: 33.10, 34.80 cc. of $0.0494\ N$ iodine soln. Subs., 0.3871, 0.3992; 16.65, 17.05 cc. of 0.1 N HCl. Calc. for $C_{14}H_{18}O_{5}N_{2}As_{2}$: N, 6.08; As, 32.60. Found: N, 6.02, 5.98; As, 32.52, 32.41.

Monosodium Salt: Five g. of the above arsonic acid was dissolved in the calculated amount of 2 N sodium hydroxide solution to form the neutral salt, and the solution was filtered in a fine stream into 95% alcohol; 3.8 g. of colorless crystals was deposited.

Analyses. Subs. (dried in oven at 105°), 0.2009, 0.2016: 33.40, 33.45 cc. of 0.0474 N iodine soln. Calc. for $C_{14}H_{16}O_{6}N_{2}As_{2}Na_{2}$: As, 29.76. Found: 29.59, 29.53.

⁴ Meister, Lucius and Bruning, Ger. pat. 206,057.

Summary

- 1. The action of chlorohydrins on amino-aryl arsonic acids has been investigated, and the properties of the resulting compounds and some of their derivatives have been described.
- 2. The condensation of ethylene dibromide with p-arsanilic acid has been studied, and the neutral sodium salt prepared.

ANALYSIS OF THE JERUSALEM ARTICHOKE¹

By A. T. SHOHL

RECEIVED AUGUST 23, 1923

The Jerusalem artichoke, helianthus tuberosus, has long been known and used as an article of food. The common books on food analysis and food values do not, however, list it.

There is an analysis by Strauss² and one by Langworthy³ to which the reader is referred for a further description of the occurrence, habits and methods of preparing the Jerusalem artichoke for table use.

This investigation was undertaken with the idea of establishing the importance of the Jerusalem artichoke in the treatment of diabetics, but suitable clinical material has not been available. The following analysis is published in the hope of suggesting such use to others.

It is well known that this tuber contains large amounts of inulin, a carbohydrate which on hydrolysis yields levulose. Inulin in the form of "Topinambur" (Jerusalem artichoke) was used in the treatment of diabetes as early as 1851 by Bouchardat.⁴ Külz⁴ in 1874 showed that inulin was burned in the body, since diabetics excreted none in the feces. Inulin has fallen into disuse since Sandmeyer,⁴ 1894, showed that dogs with partial removal of the pancreas could not utilize inulin and Mendel,⁴ 1908, objected to its use because there are no enzymes in the body to split it. Inulin is, however, hydrolyzed by dil. acids. That there is enough acid in the gastric juice to split it has been shown by Chittenden,⁵ Lewis⁶ and Okey.⁷

Strauss8 has reopened the question and found that inulin was well

utilized in severe cases of diabetes with acidosis. Goudberg⁹ examined the feces of the same cases and found no inulin. He also made metabolism studies with inulin and found increased production of carbon dioxide. The problem of the use in diabetes of 15 or 20 g. of inulin as Jerusalem artichoke is quite different from that in metabolism studies of 150 or 200 g. of pure inulin. The utilization of small amounts would make a great difference in diabetes, but very little in general nutrition. Even if the Jerusalem artichoke were inert, it would still be useful in making palatable diets of suitable bulk for diabetics on greatly restricted food intake. If suitable clinical studies confirm the work of Strauss as does our limited experience and that of Joslin and Root, 10 that there is no increased sugar elimination in diabetes; and if at the same time metabolism experiments show increased utilization of carbohydrate as demonstrated by Goudberg, Jerusalem artichoke should become a valuable adjunct in the dietetic treatment of diabetes.

Analysis

Inulin was prepared from tubers obtained in December and January, when storage is most abundant. Plimmer's method¹¹ was used. The material was a white powder, soluble in hot water and precipitated by 50% alcohol. Fehling's test gave no reduction before inversion, but positive reduction after inversion. After inversion levorotation was increased.

The juice of the artichoke was expressed and its Sörensen value (PH) by the colorimetric method of Clark¹² was found to be 5.0. The antineuritic properties have been tested in this Laboratory by Miss M. Koch and the material was found to contain water-soluble B in scant amounts.

The tubers were pared before analysis and the "edible portion" was 69% of the weight as purchased. The analysis was performed according to the methods of the Official Agricultural Chemists and the results given in Table I have been compared with those given by Strauss⁸ and Langworthy. The agreement is close.

Table I
Percentage Composition of the Edible Portion of Jerusalem Artichoke

%	Moisture	N × 6.25 Protein	True protein	Fat	Carbo- hydrate	Fiber	Ash
Strauss	72.62	1.97	0.81		13.08		1.89
Langworthy	78.7	2.5	•;•	0.2	17.5	0.8	1.1
Shohl	79.0	3.1	0.9	0.2	15.5	0.8	1.1

The carbohydrate was determined by extracting either the fresh vegetable or the air-dried material for 72 hours with boiling water. The extract

¹⁰ Joslin and Root, J. Am. Med. Assoc., 80, 1727 (1923).

¹¹ Plimmer, "Practical Organic and Biochemistry," London, 1915, p. 213.

¹² Clark, "The Determination of Hydrogen Ions," Williams and Wilkins Co., 1921.

was hydrolyzed by refluxing for 2 hours with 10% of hydrochloric acid. The levulose was determined by Benedict's method. Fifty mg. of dextrose is equivalent to 52 mg. of levulose. The carbohydrate content was found to be 15.5%.

The nitrogen determination of the extract made as described above shows that of the nitrogen listed as "protein" 71.5% is readily water-soluble and hence not protein. The amino acid nitrogen determined by Van Slyke's method¹⁴ is 27.5% of the water-soluble nitrogen.

Summary

Analysis of the Jerusalem artichoke shows that it contains 15.5% of inulin. Of the total nitrogen, 71.5% is water-soluble. It contains but small amounts of water-soluble B vitamin. Its use in the treatment of diabetes should be reinvestigated. Analysis, clinical experience and a single experiment in metabolism indicate that the Jerusalem artichoke is a valuable adjunct in the dietetic treatment of diabetes.

REACTIONS OF STRONGLY ELECTROPOSITIVE METALS WITH ORGANIC SUBSTANCES IN LIQUID AMMONIA SOLUTION. IV. ACTION OF THE ALKALI METALS ON TRIPHENYLMETHYL AND ITS COMPOUNDS

By Charles A. Kraus and T. Kawamura Received September 6, 1923

The triphenylmethyl group is the first example discovered of a class of compounds exhibiting certain characteristic properties. What attracted particular notice in the first instance was the fact that these compounds appeared to form an exception to the quadrivalence of the carbon atom. These groups, however, possess many other properties which serve to distinguish them, as well as their compounds, from other organic compounds. Thus, compounds of the triphenylmethyl group with the halogens exhibit electrolytic properties in solutions in certain solvents, while the groups also yield compounds with strongly electropositive metals, such as sodium, the properties of which characterize them as exceptional. We now know that many other elements yield compounds resembling the triphenylmethyl group as, for example, lead, tin, mercury and nitrogen, although the properties of these groups have not been extensively investigated.

Some years ago one of the present authors⁵ made the observation that the triphenylmethyl halides, when treated with alkali metals in liquid ammonia solution, yield a compound highly soluble in liquid ammonia, exhibiting a strong red color by transmitted light and a greenish-violet color by reflected light in concentrated solution. In view of the strongly electropositive nature of sodium and the electronegative nature of chlorine, it appeared probable that a reaction occurred in which sodium chloride was formed, leaving behind either the free group or a compound between this group and sodium. This reaction has accordingly been studied further.

Experimental Part

Action of Sodium on Triphenylmethyl Chloride.—The reactions were carried out in an apparatus similar to that which has already been described in an earlier number of this series.⁶

As stated, metallic sodium reacts with the triphenylmethyl halides in liquid ammonia solution. Because of the low solubility of the halides, reaction takes place somewhat slowly; this difficulty may, however, be overcome by stirring the reaction mixture by means of a stream of ammonia vapor passed through the solution. The compound formed is very soluble. Under favorable conditions it may be obtained in the form of reddish needles. No gas is evolved in the reaction with triphenylmethyl chloride.

Five g. of triphenylmethyl chloride was treated with 0.825 g. of metallic sodium in liquid ammonia. At the end of the reaction about 50 cc. of pure toluene was added, after which the bath of ammonia surrounding the reaction chamber was removed. The compound is soluble in toluene and separation was effected from the sodium chloride by filtering through a Gooch crucible in an apparatus in which the air was displaced by means of ammonia vapor. The residue on the filter consisted of sodium chloride with a small amount of sodium hydroxide, due presumably to the presence of a slight amount of moisture. The sodium chloride obtained weighed 0.98 g., corresponding approximately to one-half the sodium originally introduced.

It follows that one molecule of triphenylchloromethane reacts with two atoms of sodium to form one molecule each of sodium chloride and a compound of sodium with the triphenylmethyl group. Reaction takes place according to the equation

$$(C_6H_5)_3CC1 + 2Na = (C_6H_5)_3CNa + NaC1$$
 (1)

The compound formed between sodium and the triphenylmethyl group is very reactive, even at the temperatures of liquid ammonia. With water

- ⁵ Kraus, unpublished observations.
- ⁶ White, This Journal, 45, 779 (1923).
- ⁷ This same compound had previously been described by Schlenk and Ochs [Ber., 49, 608 (1916)], although this publication was not available when the present investigation was carried out. It may be noted that, as here prepared, the sodium triphenylmethyl compound contains one molecule of ammonia, as has since been shown by Dr. R. Rosen in this Laboratory.

it reacts to form sodium hydroxide and triphenylmethane, as was shown by characterizing the products of the reaction. Thus

$$(C_6H_5)_3CNa + H_2O = (C_6H_5)_3CH + NaOH.$$
 (2)

The compound combines readily with oxygen to form a white product, the nature of which was not determined at the time.8

With ammonium chloride in liquid ammonia, sodium triphenylmethyl yields an immediate pinkish precipitate and the red color disappears. This compound, however, is unstable, since it turns white slowly on standing at the temperature of boiling ammonia. Apparently the initial reaction consists in a replacement of the sodium by the ammonium group to form an ammonium triphenylmethyl, which subsequently decomposes according to the equation

$$(C_6H_5)_3CNH_4 = (C_6H_5)_3CH + NH_3.$$
 (3)

Triphenylmethane was characterized as an end-product in this reaction. Sodium triphenylmethyl reacts with bromobenzene and triphenylchloromethane to form tetraphenylmethane and triphenylmethyl, respectively, as will be described below. Sodium triphenylmethyl is moderately soluble in toluene and benzene, but is insoluble in petroleum ether and ligroin.

Action of Metallic Sodium on Triphenylmethane.—The nature of the compound formed between sodium and the triphenylmethyl group was further elucidated by the action of sodium on triphenylmethane in liquid ammonia solution. When triphenylmethane is treated with metallic sodium in equivalent amount in liquid ammonia, reaction takes place somewhat slowly with the formation of sodium triphenylmethyl and the evolution of hydrogen. The compound formed, as was shown by its properties at the end of the reaction, is the same as that formed by the action of sodium on triphenylmethyl chloride. This method of preparing sodium triphenylmethyl has the advantage that the solutions of the compound in ammonia may be obtained without the presence of sodium chloride. Three g. of triphenylmethane reacted completely with 0.2829 g. of sodium in the course of about an hour. Reaction takes place according to the equation

$$(C_6H_5)_3CH + Na = (C_6H_5)_3CNa + \frac{1}{2}H_2.$$
 (4)

What is perhaps most striking in the case of this reaction is the fact that hydrogen attached to a saturated carbon atom is replaced by sodium. Evidently, triphenylmethane is to be looked upon as a very weak monobasic acid. Further evidence to this effect will be adduced in a subsequent article.

Synthesis of Triphenylmethyl in Liquid Ammonia.—If sodium triphenylmethyl is present in liquid ammonia solution, we should expect it to be a comparatively weak electrolyte because of the weakly electronegative

⁸ This reaction has subsequently been studied by Dr. R. Rosen in this Laboratory. The results will appear later.

properties of the triphenylmethyl group. If, therefore, we were to treat sodium triphenylmethyl with triphenylmethyl chloride, we should expect the following reaction to take place

$$(C_6H_5)_3CNa + (C_6H_5)_3CCI = 2(C_6H_5)_3C + NaCI$$
 (5)

The sodium compound was prepared from equivalent amounts of sodium and triphenylchloromethane in liquid ammonia according to the method previously described. An equivalent amount of triphenylchloromethane was then added to the solution. In liquid ammonia, the reaction between triphenylchloromethane and sodium triphenylmethyl takes place only very slowly because of the low solubility of the former substance. When toluene is added to the mixture, both compounds are dissolved and reaction takes place immediately. The red color due to the sodium compound disappears, while the yellow color which is characteristic of triphenylmethyl makes its appearance. By stirring the solution with a stream of ammonia vapor the rate of the reaction is greatly accelerated.

Dry air was passed through this solution, whereby the free group was oxidized, the yellow color disappearing and a white amorphous precipitate being formed. The contents of the tube were transferred to a small distilling flask and the toluene was distilled. Organic impurities were removed by extraction with ether, in which the peroxide, formed as a result of the process of oxidation, is insoluble. The residue was washed with water to remove sodium chloride, and the resulting compound, which remained behind on the filter paper, was recrystallized from hot benzene. The melting point was found to be 186° sharp, which corresponds to that of the peroxide of triphenylmethyl. Triphenylmethyl is evidently formed according to Equation 5.

Triphenylmethyl in liquid ammonia reacts at once with metallic sodium to form sodium triphenylmethyl, whose presence is made evident by its characteristic red color. The compound was further characterized by the formation of triphenylmethane when water was added to the solution, according to Equation 2.

No reaction appears to take place between ammonium chloride and the free triphenylmethyl group.

Sodium triphenylmethyl appears to be entirely stable in liquid ammonia solution and in the presence of ammonia vapor at low temperatures. At higher temperatures, however, the solid decomposes. Previous investigators have noted that sodium triphenylmethane is acted upon by ammonia vapor with the formation of sodium amide and triphenylmethane.⁹ This reaction has since been studied more in detail and will be described in another paper.

Synthesis of Tetraphenylmethane.—Tetraphenylmethane may be readily synthesized through the action of bromobenzene on sodium triphenylmethyl. When the phenyl bromide is added directly to the solution of the sodium compound in liquid ammonia, reaction takes place slowly. The reaction is hastened if toluene is added to the liquid ammonia solution of triphenylmethyl. For this purpose the major portion of the ammonia is evaporated. The compound precipitated in this process must not be allowed to warm much above the boiling point of ammonia, as otherwise it is decomposed. When the excess ammonia has been evolved, phenyl bromide is added and the contents of the tube are allowed to warm slowly

⁹ Schlenk and Ochs, Ref. 7.

to room temperature. Tetraphenylmethane is formed according to the reaction

$$(C_6H_5)_3CNa + (C_6H_5)Br = (C_6H_5)_4C + NaBr$$
 (6)

Ten g. of triphenylchloromethane was treated with 1.65 g. of metallic sodium, the ammonia evaporated and toluene added as described; 55 cc. of pure dry bromobenzene was then added. The mixture was stirred by passing a stream of ammonia gas through the reaction tube at the temperature of liquid ammonia. At the end of about half an hour the bath of boiling ammonia was removed and the contents of the tube allowed to warm slowly to room temperature, after which the tube was placed in a water-bath and the contents brought to a temperature of 100°. As the temperature rises, the excess phenyl bromide dissolves the solid present, yielding a solution which is dark yellow in color. The insoluble residue consists chiefly of sodium bromide. On completion of the reaction, the contents of the tube were transferred to a small distilling flask and the excess of bromobenzene was evaporated. The residue of solid in the distilling flask was treated with ether and the mixture filtered. Any triphenylchloromethane which had not been acted upon was thus carried off with the ether. The residue on the filter consisted of tetraphenylmethane and sodium bromide, the latter being then removed with water. The residue was dried and recrystallized from hot benzene by slow cooling. From acetic anhydride the compound may be obtained in the form of long, silky needles; yield 4.35 g., or 37.8%. Tetraphenylmethane is practically insoluble in alcohol and ether, petroleum ether, ligroin, cold acetic acid and cold acetic anhydride; and is soluble in hot acetic acid, acetic anhydride, benzene, toluene and ethylene bromide. Recrystallization from hot acetic acid is recommended for the purpose of obtaining large crystals.

The molecular weight of the compound was determined in benzene by the boiling-point method. Three determinations gave 310.3, 315.4, 317.5, which is in good agreement with the calculated value of 320.

Action of Potassium on Triphenylchloromethane.—The action of potassium on triphenylchloromethane is similar to that of sodium, two equivalents of potassium being required to complete the reaction. Potassium triphenylmethyl has the same appearance as sodium triphenylmethyl and exhibits very similar properties. It exhibits, however, this marked difference, namely, that while sodium triphenylmethyl is unstable in the presence of ammonia, potassium triphenylmethyl is stable even at a temperature of 100°. Another marked difference is that it has not been found possible to synthesize the riphenylmethyl group by the action of triphenylmethyl chloride on potassium triphenylmethyl, as will be shown below.

Action of Potassium Triphenylmethyl on Triphenylchloromethane.— The attempt was made to synthesize triphenylmethyl by the same procedure which was employed in the case of sodium triphenylmethyl. In no case, however, was any evidence of the formation of the free triphenylmethyl group obtained.

Reaction was found to take place on adding triphenylchloromethane to potassium triphenylmethyl in the presence of toluene, and was completed in the course of a few minutes, the red color of the potassium compound disappearing and a yellow color taking its place, while a small amount of solid impurity was left in the bottom of the reaction

tube. The ammonia was evaporated, the residue heated to 70° and the toluene distilled under reduced pressure. The residue left in the reaction tube was treated with ligroin and then filtered. From the filtrate fine white crystals were obtained, m. p. 210° , and from the residue on the filter paper a powder was obtained, m. p. $235-236^{\circ}$. This experiment was repeated a number of times with practically the same results, the chief product of the reaction being the compound melting at 210° . From 50 to 60° % of the original compound was obtained in this form.

Tests were made for the presence of free triphenylmethyl in the toluene solution, by passing air through this solution. No trace of peroxide could be obtained, the chief product again being a compound melting at 210°. The melting point of this compound agrees with that of the so-called stable hexaphenylethane obtained by Anschütz. 10 That this compound is actually hexaphenylethane may be doubted.

Action of Calcium on Triphenylchloromethane.—Metallic calcium reacts readily with triphenylchloromethane in ammonia solution to form a reddish-brown compound. From its appearance it may be inferred that the reaction is similar to that which takes place in the case of sodium. The compound is much less stable than the corresponding sodium compound, since it decomposes almost at once at ordinary temperatures and slowly even at liquid ammonia temperatures. A white product results, the nature of which was not further studied.

Mechanism of the Reduction Process

The action of sodium on triphenylmethyl and its compounds is of interest, not only because of the light it throws on the nature of the triphenylmethyl group, but also because of the insight it yields into the mechanism of the reduction of organic compounds by means of electropositive metals. In the metal solutions, the active reducing agent is the free negative electron, and the process of reduction consists in the combination of the negative electron with the negative constituent of the carbon compound to form a negative ion. The carbon group, on the other hand, may be left in the free condition, may combine with the negative electron to form an anion, or may react with other substances present to form various compounds. In general, in the presence of excess of the free metal, that is, in the presence of excess negative electrons, the organic group will either form a stable negative ion or react with other substances, more particularly the solvent. The initial stage of the reaction, in any case, will take place as follows: $RX + 2e^{-} = Re^{-} + Xe^{-}$. Depending upon the strength of the acid RH and the strength of the base MNH2, where M is the metallic element present in the solution, reaction may take place according to the equation, Re- + H+ = RH. In other words, if the hydrocarbon RH is a sufficiently weak acid and the base MNH2 a sufficiently weak base, the salt RM will hydrolyze according to the equation, RM + NH₃ = RH + MNH₂.

In the case of triphenylmethyl chloride, the ionic reaction may be ¹⁰ Anschütz, Ann., 395, 196 (1908).

written thus: $(C_6H_5)_8CC1 + 2e^- = (C_6H_5)_8C^- + C1^-$. Since sodium triphenylmethyl is an electrolyte in ammonia, the ionic equation above properly describes the reaction.

Solutions of triphenylmethyl chloride in liquid ammonia conduct the electric current, as do also solutions of sodium triphenylmethyl. The triphenylmethyl group is an example of a numerous class of substances the members of which exhibit amphoteric properties with respect to the positive and negative charges, that is, which are capable of existing either as anions or as cations, depending upon conditions. As has elsewhere been pointed out by one of the present authors, this is a property common to practically all the free groups. In this respect the free groups closely resemble the elements with which they are allied, namely elements which are weakly electropositive and electronegative. All such elements exhibit amphoteric properties, acting either as anions or cations, depending upon conditions, and the same is true of the free groups. The chief distinction between the groups and the elements lies in the fact that, with the exception of hydrogen, all the intermediate elements in the potential series are multivalent, while the free groups are, as a rule, univalent.

The closest analog to the free groups among the elements is hydrogen, which exhibits marked amphoteric properties, being electropositive when combined with more strongly electronegative elements as, for example, the halogens, and being electronegative when combined with the more electropositive elements as, for example, the alkali metals.

Summary

The strongly electropositive metals react with triphenylmethyl chloride in liquid ammonia to form the chloride of the metal and a compound of the metal with the triphenylmethyl group. The sodium and potassium compounds are readily soluble in liquid ammonia and are fairly soluble in benzene and toluene. The solutions exhibit a strong red color and the sodium compound has been obtained in the form of red needles. The potassium compound is stable up to 100°, the sodium compound is unstable at room temperatures, while the calcium compound is unstable even at the temperature of boiling ammonia.

The free triphenylmethyl group may be synthesized by the action of triphenylmethyl chloride on sodium triphenylmethyl in the presence of toluene. A corresponding synthesis could not be carried out with potassium triphenylmethyl. The free triphenylmethyl group in liquid ammonia reacts readily with sodium to form the sodium salt.

Tetraphenylmethane is formed by the action of phenyl bromide on sodium triphenylmethyl in liquid ammonia.

THE ADDITION OF MERCURIC SALTS TO ALPHA-BETA-UNSATURATED KETONES

By Edmund B. Middleton¹ Received September 21, 1923

It is well known that mercuric salts react more or less readily with various unsaturated compounds to give products whose compositions are represented by unsaturated compound plus —HgX and —OH, if the reactionis carried out in aqueous solution, or unsaturated compound plus —HgX and —OR if the reaction is carried out in alcohol. There has been some question as to their structure, whether they are saturated compounds formed by addition to the double linkage or complex compounds of the double salt or molecular type.² For example, when ethylene is passed into a methyl alcoholic solution of mercuric acetate, it forms a compound whose composition is represented by C₂H₄. HgOCOCH₃. OCH₃ and which according to these two views, is either a molecular compound, or the saturated compound, ³ CH₂—CH₂ . The principal reason why

OCH3 HgOCOCH3

substances of this type have been regarded as molecular compounds is the ease with which the unsaturated compounds are regenerated by acids. C_2H_4 . HgX. $OCH_3 + HX \longrightarrow C_2H_4 + CH_3OH + HgX_2$. The most recent work of Adams, Roman and Sperry¹ shows conclusively that in some cases these are saturated compounds formed by addition to the double bond. The following investigation of the reaction between mercuric acetate and α,β -unsaturated ketones was undertaken with the purpose of getting further evidence on this point and on the mode of addition. The results show that α,β -unsaturated ketones with one double linkage, such as benzalacetophenone, will react with but one mol. of mercuric acetate while with dibenzalacetone, which has two double linkages, two mols. of mercuric acetate reacted. It appears from this that addition to the double linkages has taken place. Furthermore, all the compounds were white. Cinnamalacetophenone, a ketone which has two double

linkages, one of which is γ to the carbonyl, reacted with two molecules of alcoholic mercuric acetate, but the acetate compound has not been obtained in a form suitable for analysis, and when sodium chloride solution was added, insoluble amorphous precipitates of variable composition were obtained.

The simple α,β -unsaturated ketones were found to react readily with mercuric acetate in alcoholic solution. With benzalacetophenone, the products obtained analyzed for the ketone to which the groups —OR and HgOCOCH₃ had been added. The addition might have taken place in one of three ways: the groups could add 1, 4 to the conjugated system, like other metallic derivatives, to give a compound of the structure I; or they might possibly add 1, 2, according to either II or III.

Structure III may be discarded immediately because the mercury compounds obtained reacted with halogens, the halogen replacing the mercury group and α -halogen- β -alkoxy ketones were obtained. The α -bromo- β -ethoxy and α -bromo- β -methoxy addition products of benzalacetophenone have been isolated recently by Dufraisse and Gerald⁵ as intermediate products in the reaction of sodium alcoholate with α -bromobenzalacetophenone. The melting points and other properties given by these workers

$$\begin{array}{c} C_6H_5-CH=CBr-C-C_6H_5 + \dfrac{NaOR}{ROH} & C_6H_6-CH-CHBr-C-C_6H_6 \longrightarrow \\ 0 & OR & O \\ X \end{array}$$

$$C_6H_6-C=C-C-C_6H_6+NaX$$

OR
O

are identical with those of the bromine compounds obtained from the mercury derivatives of benzalacetophenone by replacing the mercury with bromine.

It now remains to distinguish between Structures I and II. In this connection, the reaction of mercuric acetate in alcohol solution with dibenzalacetone was studied. If the groups add 1, 4, we should expect to get only a monomercury compound with dibenzalacetone, C_0H_5 –

—OR and two —HgOCOCH₃ groups, and a dimercurated product could not have been obtained by 1, 4 addition alone. Furthermore, the com-

⁵ Dufraisse and Gerald, Compt. rend., 174, 1631 (1922).

pounds did not give mercuric oxide with sodium hydroxide solution as one might expect if they were —OHg— derivatives, so that mercury compounds of benzalacetophenone have Structure II, while the derivatives of dibenzalacetone are C_6H_5 —CH—CH—CH—CH—CH—C $_6H_5$. The mercury de-OR | | | | | | HgX O HgX OR

rivatives of unsaturated ketones are therefore analogous to the substances derived from the unsaturated esters.⁶

The behavior of these compounds was similar to that of mercury derivatives of other unsaturated compounds. Solutions of the acetates gave precipitates of the bromides or chlorides when treated with sodium bromide or chloride solution and they were decomposed by acids and by sodium iodide in the usual way. Also, they were found to be decomposed by Grignard reagents; ethylmagnesium bromide reacted with the bromomercuri-methoxy derivative of benzalacetophenone giving β -phenylvalerophenone. The last substance is obtained from benzalacetophenone itself and ethylmagnesium bromide.

As Dufraisse and Gerald⁵ have shown, the α -bromo- β -alkoxy- β -phenyl propiophenones lose hydrogen bromide with sodium alcoholate giving ketones of the structure, C_6H_5 —C—CH—C— C_6H_5 . These unsaturated CR

ketones reacted with alcoholic mercuric acetate but no "acetal" compound,

OR H
$$C_6H_5-C-C-C-C_6H_5, \ was \ obtained; \ the \ analyses \ indicated \ that \ the \ OR \ HgX \ O$$

product was diacetoxymercuri-dibenzoyl methane. The reaction was found to go best in dil. alcohol solution so it probably proceeds first, by the addition of —OH and —HgOCOCH₃, second, by the elimination of ROH and third, by the further addition of mercuric acetate.

Substitution in the benzene rings did not affect the reaction of the unsaturated ketones with mercuric acetate. Benzal-p-chloro-acetophenone reacted as readily as benzalacetophenone itself. But the reaction failed with benzaldesoxybenzoin. Nor were addition compounds formed with cyclopropane ketones. Dimethyl 2-phenyl-3-benzoyl-cyclopropane-dicarboxylate⁸ did not react with mercuric acetate in cold methyl alcohol solution nor did 1,2-dibenzoyl-3-phenyl-cyclopropane.⁹ Other cyclopropanes were tried without obtaining addition products.

It is interesting to compare the reactions of unsaturated ketones with

mercuric acetate and with mercuric halides. Since this work was completed. Vorländer and Eichwald¹⁰ have published an account of more compounds obtained from mercuric chloride and bromide, and unsaturated ketones. The double compounds, composed of one mol. of ketone and one mol. of mercuric halide, were stable towards alcohol, the solvent used: that is, there were no products obtained of the type, unsaturated ketone plus -OR plus -HgX. In hot alcohol they were completely dissociated into their components, mercuric halide and unsaturated ketone. The writer has found by measuring the elevation of the boiling point of acetone, that they are completely dissociated in this solvent, while the compounds described in this paper, while not entirely undecomposed, are not dissociated to this extent. The compounds obtained with mercuric halides are colored and with an unsaturated ketone with two double linkages: dianisalacetone, the product obtained by Vorländer and Eichwald, contained only one mol. of mercuric halide to one of ketone. In view of the facts known, it seems probable that the following equilibrium exists when alcoholic solutions of mercuric salts and of an unsaturated ketone such as benzalacetophenone are brought together.

When a mercuric salt such as the acetate, which is alcoholized to a relatively large extent, is used, the reaction finally goes to IV. But when HgX_2 is one of the mercuric halides, the compounds first formed are not affected by the alcohol and the equilibrium represented by Steps I, II and III may be present. In solution such an equilibrium may exist, but the compounds which finally precipitate when mercuric acetate is used are the result of the addition of —OR and $HgOCOCH_3$ to the double linkage.

Experimental Part

 α -Acetoxymercuri- β -methoxy- β -phenylpropiophenone.—A solution of 25 g. of benzalacetophenone and 38 g. of mercuric acetate in 250 cc. of absolute methyl alcohol was allowed to stand until a sample no longer gave a precipitate of mercuric oxide with sodium hydroxide sofution. The solution was concentrated by evaporation and the mercury compound crystallized; weight, 53 g. After recrystallization from methyl alcohol it melted at 115°.

Analyses. Calc. for C₁₈H₁₈O₄Hg: C, 43.31; H, 3.63; Hg, 40.2. Found: C, 43.13; H, 3.54; Hg, 40.2, 40.0.

¹⁰ Vorländer and Eichwald, Ber., 56B, 1153 (1923).

 α -Acetoxymercuri- β -ethoxy- β -phenylpropiophenone.—In a similar manner, benzalacetophenone reacted with mercuric acetate in absolute ethyl alcohol; 25 g. of ketone gave 54 g. of mercury compound. Recrystallized from ethyl alcohol, it melted at 134°.

Analyses. Calc. for C₁₉H₂₀O₄Hg: Hg, 39.1. Found: 39.3, 39.1.

α-Bromomercuri- β -methoxy- β -phenylpropiophenone.—To 25 g. of the acetate dissolved in alcohol was added drop by drop while the mixture was stirred exactly one molecular equivalent of potassium bromide dissolved in a little water. The bromide was precipitated as an oily product but solidified on standing. It was recrystallized from methyl alcohol; yield, 20 g.; m. p., 141°.

Analyses. Calc. for C₁₆H₁₅O₂BrHg: C, 36.94; Hg, 38.6. Found: C, 36.91, Hg, 39.3.

 α -Bromomercuri- β -ethoxy- β -phenylpropiophenone.—In a similar manner, the bromomercuri-ethoxy derivative was prepared by treating the acetate with one molecular equivalent of potassium bromide. The product, recrystallized from ethyl alcohol, melted at 138°.

Analysis. Calc. for C17H17O2BrHg: Hg, 37.6. Found: 37.7.

 α -Bromo- β -methoxy- β -phenylpropiophenone.—To 50 g. of the acetoxymercuric methoxy derivative of benzalacetophenone dissolved in methyl alcohol one molecular equivalent of bromine was added slowly while the mixture was stirred, and the flask containing the mercury compound was cooled with ice water. After a half hour most of the alcohol was removed by distillation and the residue dissolved in ether. The ethereal solution was washed several times with strong aqueous potassium bromide to remove mercuric bromide, and then with water. After evaporation of the ether an oil remained, most of which solidified on standing. Recrystallized from methyl alcohol, it melted at 76°.

Analysis. Calc. for C16H15O2Br: Br, 25.0. Found: 24.4.

α-Bromo- β -ethoxy- β -phenylpropiophenone.—The ethoxy compound was prepared in a similar manner by bromination of the ethoxy-mercury compound in alcohol or ether. Recrystallized from ethyl alcohol, it melted at 60–61°; 55 g. of mercury compound gave 18 g. of product.

Analyses. Calc. for $C_{17}H_{17}O_2Br$: C, 61.26; H, 5.10. Found: C, 61.49, 61.36; H, 5.18, 5.14.

The combustion of this compound was troublesome. When burned carefully in an ordinary combustion tube, a certain portion of material always came through undecomposed. It was necessary to use the cerium oxide-asbestos catalyst described by Reimer.¹¹

The compound melting at $60-6\frac{1}{2}$ ° (small needles) was always obtained except in the last run made when flat crystals melting at 74° resulted. This was evidently the other racemate possible.

Analyses (compound melting at 74°). Calc. for $C_{17}H_{17}O_2Br$: Br, 24.0. Found: 23.9, 24.2.

 α -Iodo- β -methoxy- β -phenylpropiophenone and the Ethoxy Compound.—Treatment of the mercury compounds with iodine instead of bromine gave the iodo-alkoxy addition products of benzalacetophenone.

The ethoxy compound melted at 75-76°.

Analysis. Calc. for C₁₇H₁₇O₂I: I, 33.4. Found: 33.4.

The methoxy compound melted at 96°.

Analysis. Calc. for C16H18O2I: I, 34.7. Found: 34.6.

¹¹ Reimer, This Journal, 37, 1636 (1915).

Action of Alkali on α -Bromo- β -methoxy- β -phenylpropiophenone and Addition of Mercuric Acetate to the Product.—A solution of 13.8 g. of the bromine compound in methyl alcohol was treated with one molecular equivalent of sodium methylate. The solution was heated until it became neutral. It was then poured into water and extracted with ether. The oil obtained from the ether layer was distilled at 6 mm. The fraction boiling at 200–205° was collected; yield, 8 g. The ethoxy compound was prepared in the same way, by the action of sodium ethylate on the α -bromo- β -ethoxy ketone.

The methoxy compound was dissolved in 90% methyl alcohol and treated with two molecular equivalents of mercuric acetate. As the solution stood, a white crystalline substance was gradually deposited. After 24 hours 80% of the calculated amount had crystallized. It was only very slightly soluble in alcohol; m. p., 237°. The analysis indicated that the product was the diacetoxymercuri derivative of dibenzoyl methane.

Analyses. Calc. for $C_{19}H_{16}O_6Hg_2$: C, 30.75; H, 2.14; Hg, 54.1. Found: C, 30.20; H, 2.21; Hg, 54.5, 54.6.

The ethoxy compound reacted with mercuric acetate in ethyl alcohol to give the same mercury compound, shown by analysis and by a mixed-melting-point determination.

A suspension of 10 g. of the compound melting at 237° in an excess of dil. hydrochloric acid was warmed until it had completely decomposed. The oil which remained was separated and crystallized from alcohol; yield, 90%. It melted at 80°, gave a red color with ferric chloride, and a copper derivative. A mixed-melting-point determination showed it to be dibenzoyl-methane.

Reaction of Ethylmagnesium Bromide with α -Bromomercuri- β -methoxy- β -phenyl-propiophenone.—The mercury compound was only very slightly soluble in ether, 5 g. was ground to a fine powder and added slowly to three molecular equivalents of ethylmagnesium bromide. A vigorous reaction took place. When all of the solid had been added, the clear solution was poured into ice water. The ether solution contained an oil which later solidified. It was recrystallized several times from alcohol to free it from mercury diethyl; m. p., 63°. The substance proved to be β -phenyl-valerophenone.

Analyses. Calc. for C₁₇H₁₈O: C, 85.7; H, 7.61. Found: C, 85.7; H, 7.54.

Reaction of α -Acetoxymercuri- β -alkoxy- β -phenylpropiophenone with Acids and with Potassium Iodide.—The mercury compounds were slowly decomposed by cold hydrochloric acid and rapidly by hot acid. The products were mercuric chloride and benzalacetophenone. When the mercury compounds were dissolved in alcohol and hydrogen sulfide was passed through the solution, there was an immediate precipitate of mercuric sulfide. The filtrate from the sulfide on concentration yielded benzalacetophenone. When boiled with an excess of aqueous potassium iodide, the mercury compounds were decomposed, the solution became alkaline and on cooling benzalacetophenone was recovered from the solution by extraction with ether.

Reaction of Dibenzalacetone with Mercuric Acetate.—To 5 g. of dibenzalacetone was added 13.6 g. of mercuric acetate in 100 cc. of absolute methyl alcohol. After 48 hours 15 g. of product had precipitated. Recrystallized from methyl alcohol, in which it is somewhat soluble, the compound melted at 183°. Analyses showed it to be the dimercurated compound, two methoxyl and two mercury groups having been added.

Analyses. Calc. for C₂₃H₂₆O₇Hg₂: C, 33.85; H, 3.21; Hg, 49.2. Found: C, 33.74; H, 3.10; Hg, 49.0, 49.2.

The acetoxymercuri-ethoxy derivative of dibenzalacetone was prepared by carrying out the reaction in ethyl instead of methyl alcohol. The acetate melted at 188-190°.

Analysis. Calc. for C25H30O7Hg2: Hg, 47.6. Found: 47.7.

 α -Acetoxymercuri- β -methoxy- β -phenyl-p-chloropropiophenone.—A solution of 10 g. of benzal-p-chloro-acetophenone and 13 g. of mercuric acetate in 300 cc. of absolute methyl alcohol, prepared by heating the mixture for a short time on the steam-bath, was allowed to stand several days, concentrated to 50 cc. and again allowed to stand, when about 50% of the mercury compound was slowly precipitated. Recrystallized from methyl alcohol, it melted at 124°.

Analysis. Calc. for C₁₈H₁₇O₄ClHg: Hg, 37.6. Found: 37.6.

Sodium chloride solution was added to the filtrate from the acetate and the chloride precipitated. Recrystallized from methyl alcohol, it melted at 160° .

Analysis. Calc. for C₁₆H₁₄O₂Cl₂Hg: Hg, 39.3. Found: 39.0.

Summary

- 1. The reaction of several α,β -unsaturated ketones with alcoholic mercuric acetate has been studied. The products obtained were saturated ketones formed by the addition of the groups —HgX and —OR to the double linkage.
- 2. The reaction of unsaturated ketones with mercuric acetate has been compared with that of mercuric halides.
- 3. Reactions and derivatives of the mercury compounds have been described.

CAMBRIDGE 38, MASSACHUSETTS

NOTES

Absorption of Halogens by Mercurous Salts: Preliminary Note.— The present work grew out of an attempt to make a more effective mercurial preparation for external application by treating calomel with iodine. In spite of the large amount of work which has been done on various complex mercuric compounds, the mixed mercuric salts, X—Hg—Y, have not been prepared by the action of halogens on mercurous compounds. During the present study, mercurous chloride, sulfate, and nitrate have been treated with alcoholic solutions of iodine and bromine in excess. Mercurous chloride yields mercuric iodochloride, HgICl, and mercuric bromochloride, HgBrCl. The sulfate yields di-iodomercuric sulfate, (IHg)₂SO₄, and a perbromide, (BrHg)₂SO₄.Br₂. The latter compound reacts with dry chlorine to give dichloromercuric sulfate, (CIHg)₂SO₄. The nitrate gives a per-iodide, (IHgNO₃)₂.I₂, and a perbromide, (BrHg-NO₃)₂.Br₂. The former compound, when treated with chlorine, differs from the corresponding sulfate by giving a perchloride, (CIHgNO₃)₂.Cl₂.

It is too early to discuss definitely the constitution of this series of compounds of mercury. They exhibit a number of interesting peculiarities

¹ Ditte, Compt. rend., 87, 794 (1879); 92, 353 (1881). Varet, ibid., 123, 497 (1896). Harth, Z. anorg. Chem., 14, 323 (1897). Dobrosserdoff, J. Russ. Phys. Chem. Soc., 33, 303, 387 (1901). which are being actively studied by physicochemical means. The study of their therapeutic effects may lead to interesting developments. As they contain easily reactive halogen atoms, they might be useful in making other compounds of mercury, or in organic synthesis.

The experimental details of the preparation and properties of the substances, as well as the analytical data, will be published in a later paper on their constitution.

The Catalytic Bromination of Aliphatic Acid Chlorides.—The use of iron, ferric chloride, aluminum chloride, etc., in brominating and chlorinating aromatic compounds has found widespread application. In the aliphatic series, however, the use of iron as a catalyst in introducing bromine within the molecule has been limited chiefly to saturated and unsaturated hydrocarbons.

Meyer¹ and Kronstein² have presented a series of papers dealing with the bromination of hydrocarbons using iron as a catalyst. Willstätter and Bruce³ used iron powder in preparing 1,2-dibromocyclobutane, and recently Mereshkowsky⁴ has studied the ratio of reaction products obtained in the bromination of hydrocarbons and their bromine derivatives by using iron wire, ferric bromide, aluminum, and aluminum trichloride as catalysts. In brominating acetic acid and its homologs the use of sulfur as catalyst is well known.

During the course of researches on derivatives of camphoronic acid, $(CH_3)_2C(COOH)-C(CH_3)(COOH)-CH_2COOH$ (a description of which will appear later), it was found necessary to brominate anhydrocamphoronyl chloride, $C_6H_{11}(CO)_2OCOCl$. The bromination hitherto has been carried out by Bredt⁵ either by heating one or both isomers with bromine in a sealed tube at elevated temperatures, or in an open vessel on the waterbath, the reaction product being a mixture of two isomeric bromo-anhydrocamphoronyl chlorides in which it is known that the bromine is attached to the primary carbon atom of the molecule. The latter scheme required about 12 hours for complete reaction to take place.

The above procedure was modified by treating anhydrocamphoronic acid, C₆H_{II}(CO)₂OCOOH, formed in quantitative yields by heating pure, optically-active camphoronic acid under a vacuum at 180° in an oil-bath with 1.1 molecular equivalents of phosphorus pentachloride in a flask

¹ Meyer, Ber., 24, 4247 (1891); 25, 3304 (1892).

² Kronstein, Ber., 24, 4245 (1891); 26, 2436 (1893); 54, 1 (1921).

⁸ Willstätter and Bruce, Ber., 40, 3983 (1907).

⁴ Mereshkowsky, Ann., 431, 113 (1923).

⁵ Bredt, Ann., 299, 142 (1899).

bearing a ground-glass tube and condenser together with a separatory funnel sealed to its side. The mixture was warmed and when the reaction had ceased, without distilling the phosphorus oxychloride, a small amount of iron powder (0.2-0.5 g.) was added. Then, while the mixture was heated on the water-bath, 1.1 molecular equivalents of bromine was slowly added through the separatory funnel. A violent bromination of the camphoronyl chlorides followed. After all the bromine had been added the mixture was heated for 45 minutes to insure complete reaction. At the end of this time, when no fumes of bromine could be detected, the flask was removed and allowed to stand at room temperature for 24 hours to permit the crystallization of the α -bromo-anhydrocamphoronyl chloride. The contents of the flask were filtered and the crude product, obtained in yields of 75%, was repeatedly washed with small amounts of absolute ether to remove both its readily soluble isomer and ferric bromide. The solid was dissolved in hot benzene, boiled with Norite two or three times and finally allowed to cool. Transparent crystals of the pure product melting at 168° were obtained. The original filtrate contained some α -bromo acid chloride together with ferric bromide and the β -, or isomeric, bromo acid chloride. The latter compound has never been obtained in a pure state.

This method of catalytic halogenation appears to have considerable value in the catalytic preparation of α -halogen acids. It is the intention of the writer to continue investigation of the reaction, extending it not only to other acid chlorides, but also to other classes of aliphatic compounds to which it has not been applied.

CHEMICAL LABORATORY UNIVERSITY OF ILLINOIS URBANA, ILLINOIS Received July 23, 1923

WALTHER F. GOEBEL

The Purity of Alpha-Gamma-Dichlorohydrin Prepared by the Action of Hydrogen Chloride on Glycerol.—In the preparation of α, γ -dichlorohydrin from glycerol by the action of hydrogen chloride there is the possibility of forming considerable amounts of α, β -dichlorohydrin (the dichloride of allyl alcohol). The complete separation of such a mixture by distillation would be very difficult. In order to obtain information in regard to the purity of the dichlorohydrin prepared in this way, we investigated the action of p-nitrobenzoyl chloride on the final product of the reaction which was collected over a 3° range and over a 7° range. The preparation and distillation was carried out as described in "Organic Syntheses," Vol. II, p. 29. Five g. of the material was mixed with 20 g. of pyridine and 8 g. of p-nitrobenzoyl chloride; the mixture was heated for 3 hours on the steam-bath, then allowed to stand overnight and finally treated with dil. hydrochloric acid and extracted with ether. After the removal of nitrobenzoic acid by means of aqueous sodium carbonate, the ether

was dried and evaporated. From the 3° portion 10.2 g. of ester was obtained, m. p. $55-58^{\circ}$ (94% yield), and 10.0 g. from the 7° portion, m. p. $53-57.5^{\circ}$ (92% yield). The pure ester after several recrystallizations melted at $58-59^{\circ}$.

Calc. for C9H9O4NCl2: Cl, 25.5. Found: 25.4.

The isomeric ester of α,β -dichlorohydrin was made in a similar fashion from the allyl alcohol dichloride. It melted after several recrystallizations at $35.5-37^{\circ}$.

Calc. for C9H9NCl2: Cl, 25.5. Found: 25.7.

A mixture of 90% of the α,γ -ester and 10% of the α,β -ester melted at $26\text{--}48^\circ$. The crude product from the 3° and 7° portions must, therefore, have contained much less than 10% of the isomeric ester. Since the yields of this crude ester were 94 and 92%, the original portions must have contained at least 91% and 89% of α,γ -dichlorohydrin (assuming the melting points corresponded to 97% purity). Considering the losses in the manipulation, etc., it is probable that the purity is several per cent. higher than this; the relatively high melting point of the crude ester points to the almost complete absence of the α,β -dichlorohydrin from both portions.

CAMBRIDGE 38, MASSACHUSETTS Received August 13, 1923

NEW BOOKS

The Phase Rule and the Study of Heterogeneous Equilibria: an Introductory Study. By A. C. D. RIVETT, D.Sc., Associate Professor of Chemistry in the University of Melbourne. Oxford University Press, American Branch, New York, 1923. 204 pp. 118 figs. 20 × 13 cm. Price \$3.50.

This little book by Professor Rivett is a welcome addition to our very limited textbook literature of the phase rule. Outside of Roozeboom's "Die heterogenen Gleichgewichte," which is too encyclopedic for any but a specialist, and Bancroft's "Phase Rule," which has had its greatest use in bringing to the attention of chemists the value of the phase rule at a time when it was but little known, there have been only two readable books on the phase rule, as far as the reviewer knows, which could be put in the hands of a graduate student or an investigator needing an acquaintance with the phase rule for the purposes of his research—namely, Findlay's, "Phase Rule" and Clibbens' "Principles of the Phase Theory." This third book fulfils the requirement of being another readable book—perhaps more so than Clibbens—and at the same time presents, in clear and understandable language much material that is not found in either of the others. The author states that it is not "either a treatise or a book of reference," but is intended as "an introduction to the subject." In the opinion of

the reviewer, it will be most valuable if used in conjunction with Findlay rather than as an independent introduction, since each of the texts supplements the other. Findlay, as pointed out by the author in his preface, has confined himself quite largely to the study of condensed systems, and Rivett has repaired that omission by giving us a most excellent development of one- and two-component systems including the vapor phase. The treatment of three-component and four-component systems is also complete to a degree that would hardly be expected in a book of but two hundred pages. It is of course a necessity that these things have been done by excluding some other things—and they are precisely the condensed systems which Findlay has treated so admirably. Each text supplements the other, and the pair give a much more satisfactory introduction than either alone.

Professor Rivett's book is written in a clear and logical style, which never leaves the reader in doubt as to his meaning. Diagrams and typography are also good. The reviewer feels that Professor Rivett would run less danger of losing a student's interest if he had used more specific examples in the text, even at the expense of some of the general discussion. Of the one hundred and eighteen phase-rule diagrams only a half dozen have specific components attached to them, and statistical data are not given for a single system. It would not be necessary to expand the book by very many pages in order to include enough data to convince the student who is being introduced to the phase rule via Professor Rivett's book that the rule works for real concrete systems made up of real chemicals.

Landolt-Börnstein Physikalisch-Chemische Tabellen (Physical-Chemical Tables). Fifth edition, revised and enlarged. By Dr. Walther A. Roth, Professor an der Technischen Hochschule, Braunschweig, and Dr. Karl Scheel, Professor an der Physik.-Techn. Reichsanstalt, Charlottenburg. Julius Springer, Linkstr. 23-24, Berlin W. 9, Germany. Two volumes, xvi + 1695 pp. 1 fig. 20 × 28 cm. Price \$45.00.

The new edition of these invaluable tables is very welcome. The last (fourth) edition appeared in 1912; eleven years is a long interim to be covered, at the present rate of growth of physics and chemistry.

The increased size of the present edition reflects this rapidity of growth. The new edition has nearly 1700 pages as compared with the 1300 pages of the old edition. A number of entirely new chapters have been added, dealing with radioactivity, spectrum analysis, electric phenomena in gases, the physics of the atom, and crystal structure, while the old chapters, particularly those dealing with the critical state, with electromotive forces, and with solubility, have been very greatly enlarged. A further addition is a special index covering the properties of the most important and best-known common substances.

Both of the original editors are now dead, so that we owe the present edition to Walther A. Roth, Karl Scheel, and half a hundred German collaborators.

These volumes, like their predecessors, constitute a splendid achievement. At least until our new International Critical Tables shall have appeared, they will be indispensable to every investigator or laboratory engaged upon research in physical or chemical science. To be sure, they do not present all the data for the various constants treated and frequently, extracts only are given of many important modern data, but in the great majority of cases these extracts should be adequate and, if they are not, the references to the original sources are available. The data, too, have not been as critically examined as might be desired, and the index is far too small and too poorly cross-referenced for so large and multifarious a subject matter. However, to have collected and arranged such a colossal number of data so carefully and so well, and to have printed them so clearly and indeed beautifully, merit our admiration and gratitude.

This new edition can also be looked upon as one more forward step in the resumption of the orderly progress of science in Germany.

ARTHUR B. LAMB

Les Isotopes (Isotopes). By Professor A. Damiens, of the Faculty of Pharmacy, Paris. Gauthier-Villars, Quai des Grands-Augustins, 55, Paris, 1923. ix + 118 pp. 33 figs. 25.5 imes 16.5 cm. Price 12 fr.

It may well occasion some surprise, in view of the uniquely authoritative nature of Aston's treatise on this subject, as well as its eminently readable character, that another author has thought it worth while to prepare a book of almost the same size covering nearly the same field, and bearing the same title.

This surprise can only increase when it is learned that Aston's "Isotopes" has recently appeared in French translation. The present author, however, has recognized that since most of the progress in this field has been made by physicists, it is they who have taken in hand the enlightenment of the general scientific public as to the results of their labors. The vast theoretical importance of these results to chemistry makes it desirable that the experimental evidence in the case should be collected and critically examined by an open-minded chemist, and subsequently presented for the examination of others in such detail and with such a marshalling of facts that no critical student need feel the necessity of accepting any longer the ready-made opinions of workers in other fields as to the importance to him of the phenomenon of isotopy.

This task has been well performed. The book in parts is very complete. Many of the crucial experiments, as well as the confirmatory researches which followed them, especially the more recent ones, are reported with a

wealth of experimental detail, cuts, and documentation such as one would hardly expect to find in a summary treatise of this sort. With sound judgment the author has condensed the section on radioactivity and positive rays, probably in view of the excellent accounts of this field already published, and has correspondingly amplified his examination of the atomic weight work, the partial separations of isotopes, and the researches on such properties as melting point, density, index of refraction, etc., which lend themselves to comparative "large-scale" study.

The book seems relatively free from serious errors or omissions, considering the author's lack of experience in these rather special domains of investigation, but the discussion of the radioactivity of the atomic weight samples of active lead (pp. 36-37) is not especially luminous proportionality between radioactivity and atomic weight, found by Richards and his co-workers, is presumably due (a) in some of the minerals to an admixture of thorium lead; (b) possibly to a partial decay of the radium-D content after the separation of the lead from the mineral; and (c) in some cases perhaps to an accidental admixture of traces of radium-D in the preliminary preparation of the sample. A failure to make the measurements under strictly comparable conditions might also be suspected, except that the activities of differently purified samples of the same mineral show excellent agreement. The author seems troubled by a remark of Richards and Wadsworth to the effect that the radioactivity of their specimens was due to radium-E. It is obvious that the measurable β -ray activity of a pure radium-D preparation which has been left for 20 or 30 days is always due almost solely to radium-E, however completely this product may have been "removed in the preliminary purification." The length of the half-life of Ra-D (24 years) is hardly a reason for surprise at this conclusion. It does not seem quite true (p. 55) that in attempting to separate isotopes one should always employ at the start only materials of the highest purity. Among minor slips of the pen one notes "plomb" for "baryum" on the last line of p. 1, and COCl2 for COCl on pp. 93 and 111.

In addition to being valuable as a compilation, the book is interesting for the assumption which is its principal excuse for being, namely, that a worker in one field may profitably attempt a comprehensive criticism of the methods and conclusions in another. In this case the author is to be commended for the good will and thoroughness with which this task has been attempted. He does well to emphasize again the axiom that when one tries to display minute differential effects, nothing but the most elaborate recital of precautions, purifications and tests can be convincing. Nor has one very important point escaped him. Two different states of mind have animated the workers in this field,—one group has experimented with a view to the confirmation of preconceived theories, others have only sought to make numerous and precise measurements, with minds freed from the

start, of all premature conceptions. Brilliant and important advances have resulted from both methods of work.

NORRIS F. HALL

La Technique Industrielle des Parfums Synthétiques (The Industrial Technique of the Manufacture of Synthetic Perfumes). By René Sornet. Gauthier-Villars, 55, Quai des Grands-Augustins, Paris, 1923. x + 135 pp. 14.5 × 22.5 cm. Price, unbound, 10 fr.

Although the manufacture of synthetic perfumes is a comparatively new industry a great deal has already been accomplished in this branch of applied science, and it represents a field of research which still continues to attract the attention and interest of chemists in many lands. It is well known that France has long occupied a leading position in the cultivation of flowers from which some of the most delicate perfumes are obtained, and that the consequent development in that country of the art of perfumery has led to the establishment of very large industries. An impetus was thus given to the systematic investigation of these floral products and also of the so-called essential oils from other sources, many of which are used in perfumery. As a result of such studies it has been found possible to produce by synthetical methods many of the more important odorous substances occurring in nature, and these achievements have led to a very great expansion of the perfume industry. It has furthermore been observed that a large number of definite organic compounds which have not as yet been found to occur in nature possess such fragrant properties as to render them of value in the manufacture of perfumes and they are now extensively utilized for this purpose. The literature in this particular domain of chemical science has consequently become very voluminous, and many patents have been issued for the protection of individual products. These considerations appear to have suggested the compilation of the little volume under notice, which is specially designed to supply the technical information that is not to be found in the various textbooks of organic chemistry or in those laboratory manuals which more specifically describe the methods for preparing organic compounds. It may be noted, however, in this connection that it was not the purpose of the author to include any information concerning the composition or manufacture of finished perfumes, which are usually of a complex nature.

The subject matter of the present work is divided into five parts which comprise, respectively, the alcohols, aldehydes, ketones, esters, and substances of diverse character such, for example, as coumarin and musk. Under each of these divisions a number of compounds are described, together with the reactions which take place in their formation, and there are some citations of current literature. The work is concisely written and, although limited in its scope, will doubtless be found of value to those who are interested in the industrial production of synthetic perfumes.

THE CRYSTAL STRUCTURE OF MAGNESIUM STANNIDE

By Linus Pauling Received May 21, 1923

Introduction

The temperature-composition diagram¹ of the binary system, magnesiumtin, shows a pronounced maximum corresponding to the composition Mg₂Sn. This compound is described² as cubic with octahedral habit and complete octahedral cleavage. For the purpose of obtaining information regarding the nature of intermetallic compounds, crystals of magnesium stannide, Mg₂Sn, have been investigated by means of X-rays, resulting in a complete determination of their structure. No crystal structure determination for an intermetallic compound has been previously reported.

By melting the calculated amounts of magnesium and tin in an iron crucible under a mixture of potassium and magnesium chlorides, and cooling slowly, a mass of magnesium stannide was obtained from which individual crystals could be cleaved. The X-ray data were obtained from Laue and spectral photographs, treated as described by Dickinson.³ I wish to express my thanks to Dr. Roscoe G. Dickinson for his advice and active interest in this research.

The Determination of the Structure

Spectral data from a (111) face of a crystal of magnesium stannide are given in Table I. Using the value of 3.591 for the density,² these data place $n^3/m = 0.248$ for the first reflection. No reflections were found on the Laue photographs with values of $n\lambda$ less than 0.26 Å. U., calculated for the unit containing four Mg₂Sn, with n = 1, and $d_{100} = 6.78 \pm 0.02$ Å. U.

- ¹ Kurnakow and Stepanow, Z. anorg. Chem., 46, 177 (1905).
- ² Sustschinsky, Z. Krist., 38, 265 (1904).
- ³ Dickinson, This Journal, 44, 276 (1922).

As the lower limit of X-rays present in the spectrum was 0.24 Å. U., a larger unit of structure is not indicated.

A symmetrical Laue photograph through the (111) face showed a trigonal axis and three reflection planes; consequently only arrangements derived from point-groups $T_{\rm d}$, O and O_h were treated. No planes but those with all indices odd gave values of $n\lambda$ less than 0.50, although a large number of other planes were in positions favorable for reflection, so treatment was given only to arrangements based on a face-centered lattice. There are three ways⁴ of arranging $4Mg_2Sn$ with these restrictions, irrespective of any assumptions regarding the equivalence of atoms of one element. These are

The intensity of the third order (111) reflection is greater than that of the second order, and the structure factor, $S = \sqrt{A^2 + B^2}$, must be greater for the third order. For Arrangements II and III, the corresponding values are

$$n=2$$
, $A=4\overline{Sn}$, $B=0$; $n=3$, $A=4\overline{Sn}-4\overline{Mg}$, $B=\pm 4\overline{Mg}$.

On the very safe assumption that an atom of tin scatters X-rays more strongly than an atom of magnesium, the value of S for the third order is less than that for the second order, eliminating these two arrangements.

For Arrangement I reflecting planes may be divided into three classes, which have the following values of S.

```
Class I: hkl one odd, two even; n=1, S=0; n=2, S=4\overline{\text{Sn}}-8\overline{\text{Mg}} Class II: hkl all odd; n=1, S=4\overline{\text{Sn}} Class III: hkl two odd, one even; n=1, S=0; n=2, S=4\overline{\text{Sn}}+8\overline{\text{Mg}}.
```

On the previously made assumption regarding relative reflecting powers, the values for the structure factor of the classes of planes increase in this

order: I, II, III. Intensity data showing the extent of the agreement with this structure are given in Tables I and II. In comparing intensities of two planes reflecting at the same wave length, if the intensity of the plane with the smaller value of d/n is larger than that of the other, the structure factor of the first must be greater than that of the second. No intensity relations not accounted for by the above arrangement were observed.

Discussion of the Structure

The structure determined for magnesium stannide is the one known as the calcium fluoride arrangement.⁵ It places eight magnesium atoms around each tin atom at the corners of a cube, and four tin atoms around each magnesium atom at tetrahedron corners. The sum of the atomic radii of magnesium⁶ and tin⁷ obtained from the distance between atoms in the metals is 3.01 Å. U. (from gray tin) or 2.80 (from white tin); the closest approach of tin and magnesium atoms in magnesium stannide is 2.94 ± 0.01 . There is no similarity in the way in which an atom of tin or magnesium is surrounded by other atoms in the metals and in this compound.

Crystals of sodium cadmide, NaCd₂, reported from goniometrical measurements as cubic, were prepared by the method of Kurnakow.⁸ Each of several Laue photographs taken from three different crystals with the beam perpendicular to an octahedral face showed a 3-fold symmetry axis lying in three symmetry planes. The photographs were, however, so complicated that it was not found possible to assign indices with certainty to many of the spots even on the symmetrical photographs. It was accordingly not possible to determine the apparently very complex structure.

W. H. and W. L. Bragg, Proc. Roy. Soc., 89A, 474 (1913).

⁶ Hull, Phys. Rev., [2] 10, 661 (1917).

Bijl and Kolkmeier, Proc. Acad. Sci. Amsterdam, 21, 494 (1919).

⁸ Kurnakow, Z. anorg. Chem., 23, 459 (1900).

In view of the lack of a simple valence relation between the atoms, complex atom-groups may be formed in sodium cadmide in a way similar to the formation of Pb_2^- ions in a solution of sodium plumbide, $NaPb_2$, in liquid ammonia, preventing a simplicity of structure.

Summary

Crystals of the intermetallic compound magnesium stannide, Mg₂Sn, have been prepared and investigated by means of Laue and spectral photographs with the aid of the theory of space-groups. The intermetallic compound has been found to have the calcium fluoride structure, with $d_{100}=6.78\,\pm\,0.02$ Å. U. The closest approach of tin and magnesium atoms is $2.94\,\pm\,0.01$ Å. U.

THE THEORY OF EMULSIFICATION1

By Philip Finkle, Hal D. Draper and Joel H. Hildebrand Received June 6, 1923

To disperse one liquid in another in the form of an emulsion requires the doing of work upon the system equal to the product of the interfacial tension multiplied by the increase in surface. An emulsion produced by the mechanical agitation of two pure, incompletely miscible liquids is, therefore, always unstable, the drops of dispersed liquid coalescing upon contact to decrease the interfacial area. To stabilize an emulsion a suitable third substance must be added. Many very effective emulsifiers are known but there has been thus far no altogether satisfactory way to predict the relative powers of different emulsifying agents, either to stabilize the emulsions or to determine which of the two liquids shall be dispersed in the other. Some very useful criteria yielded by experience are more in the nature of rules than theories. We will refer to some of these briefly and then proceed to elaborate an hypothesis which seems to account for the behavior of all emulsifying agents for which we have the data to apply it.

To form a stable foam or emulsion requires that the films of enclosing liquid which separate the bubbles or drops, respectively, shall be stable. This cannot be the case with a pure liquid, since a film represents a surface which is far from the minimum possible. It was shown by Rayleigh that a film is stabilized by the addition of some substance which, by virtue of high adsorption at the surface, greatly lowers the surface tension. In such a case the surface tension is larger at a fresh surface than at an old surface, at which there has been time for the adsorption to take place by diffusion,

Kraus, This Journal, 29, 1557 (1907).

¹ Presented at the Colloid Symposium held at Madison, Wis., in June, 1923, under the auspices of the Department of Chemistry of the University of Wisconsin.

so that if an old surface is threatened with rupture, the new surface thereby formed is stronger than the old, and further strain is diverted from the threatened point. This is the effect of soap in stabilizing the water films between the bubbles in soap suds. Since the globules of dispersed liquid in an emulsion must likewise be held apart by a stable film of the enclosing liquid, the presence of a solute which is highly adsorbed at the interface stabilizes the film and prevents the coalescence of the drops. Thus, soap, which is adsorbed at a water-oil surface as well as at a water-air surface, stabilizes a water-oil emulsion as it does a water-air "emulsion." The difficulty enters when we consider the difference in the type of the emulsion produced by soaps of the alkali metals on the one hand, which disperse the oil in the water, and heavier metal soaps on the other hand, which disperse the water in the oil, for we have adsorption and lowering of the interfacial tension in both cases, and might expect either an oil or a water film to be stabilized.

Bancroft² connects the type of emulsion with the phase which is the best solvent for the emulsifying agent. He says,

"If the adsorption of the emulsifying agent lowers the surface tension on the water side of the interface more than it does on the oil side, the interface will tend to curve so as to be convex on the water side, and we shall have a tendency to emulsify oil in water. If the adsorption of the emulsifying agent lowers the surface tension on the oil side of the interface more than it does on the water side, the interface will tend to curve so as to be concave on the water side, and we shall have a tendency to emulsify water in oil. The simplest way, then, to emulsify oil in water is to add a water-soluble colloid which is adsorbed strongly at the interface and the simplest way to emulsify water in oil is to add an oil-soluble colloid which is adsorbed strongly in the interface."

The idea of a film with two surface tensions, one on the oil side and another on the water side, is rather disconcerting, for no one is likely to measure separately the surface tensions on two sides of an interface, and we have evidence, furthermore, that the emulsifying agent may form films at the interface which are but one molecule thick.³ The general rule which this theory implies, that the external phase is the one which is the best solvent for the emulsifier is undoubtedly true in most instances. Thus, the alkali metal soaps are soluble in water and disperse oil in water, while the soaps of iron, zinc, aluminum, etc., which are more soluble in benzene and other solvents of low polarity, disperse the water in the other liquid. A contradiction exists, however, in the case of a fatty acid, such as oleic acid, which, though soluble in benzene and not in water, gives an unstable emulsion of benzene in water.

Bhatnagar,4 on the basis of considerable experimental data, has arrived

² Bancroft, "Applied Colloid Chemistry," McGraw-Hill Book Co., 1922.

³ Langmuir, (a) Met. Chem. Eng., 15, 468 (1916); (b) This Journal, 39, 1848 (1917); (c) Adam, Proc. Roy. Soc. London, 99A, 336 (1921); (d) 101A, 452 (1922); (e) Griffin, This Journal, 45, 1648 (1923).

4 Bhatnagar, J. Chem. Soc., 119, 61, 1760 (1921).

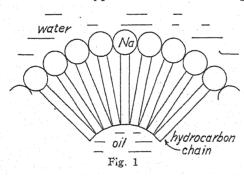

at what may likewise be regarded as a rule rather than a theory. "All emulsifying agents having an excess of negative ions adsorbed on them and wetted by water will yield oil-in-water, emulsions, while those having an excess of adsorbed positive ions and wetted by oil give water-in-oil emulsions."

The role played by the orientation of the molecules in the interface in determining the direction of curvature was suggested by Langmuir,^{3a} who said,

"This theory also affords an explanation of the mechanism by which colloids are formed. If a film of closely packed oleic acid molecules covers the surface of water to which sodium hydroxide has been added, OH group are adsorbed by the COOH radicals, causing an expansion of the lower side of the film without a corresponding expansion of the upper side. This results in the bulging of the film downwards in spots so that it finally detaches itself in the form of particles, the outer surfaces of which consist of COOH groups together with the adsorbed OH, while the interior consists of the long hydrocarbon chains.

"The size of the colloidal particles is determined by the difference in size between the two ends of the molecules, just as the size of an arch is dependent upon the relative sizes of the two ends of the stones of which the arch is constructed."

Harkins, Davies and Clark⁵ applied essentially the same view to explain the reversal of type in emulsions conecting the differences between sodium

and potassium oleates as emulsifying agents with the number of oleate radicals in the molecule of the soap.

It is possible to test the orientation hypothesis in a very striking way in the case of the soaps, where the work of Langmuir and of Harkins and co-workers seems amply to justify the assumption that at an interface between

water and some liquid of low polarity, such as benzene, any soap would form an interfacial film, which might be as little as one molecule thick, whose molecules would be oriented with the non-polar hydrocarbon chain in the benzene and the polar metallic end in the water.

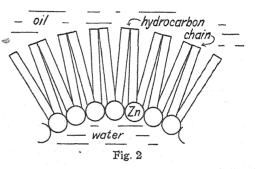

Now, if the polar group, in the water, occupies more space than is necessary for the closest packing of the hydrocarbon chain, the latter can be packed more closely if the film is convex on the water side, as illustrated in Fig. 1, in a highly idealized form. It is obvious that the direction and degree of curvature, if this hypothesis is correct, should vary, first, with the atomic volume of the metal, being more convex the larger this volume, and second, with the number of hydrocarbon chains attached to a

⁵ Harkins, Davies and Clark, This Journal, 39, 354, 541 (1917).

single metallic atom, according to its valence. Zinc soap, for example, would correspond to Fig. 2, making the interface convex towards the "oil" side; while an aluminum soap should give still more curvature and more stable emulsions of water in oil. Where the cross section of the hydrocarbon chain and of the metallic end are of the same magnitude, there will be no tendency to curvature, and no very stable emulsion, in spite of the high adsorption at the interface which is still possible.

The relative sizes of the metallic atoms in the various soaps may be inferred from the atomic volumes of the metals, and from their atomic

diameters in the free state and in compounds. Values are given in Table I. The atomic diameters are according to Hull, Bragg, and Richards, respectively. Of course, hydration may modify the effective atomic domain, but since, for example, the hydration of silver ion can hardly be as great as that of sodium ion, this fac-

tor may be expected to increase rather than to oppose the effect of the differences evident in Table I.

Application of the theory to these figures would indicate that the ability of soaps of calcium, potassium, sodium and silver to emulsify oil in water would

Table I Relative Sizes of Atoms

decrease in the order given; or, viewed from the other angle, their ability to emulsify water in oil should increase in this order; that the soaps of the divalent metals, calcium, magnesium and zinc, should have much less

⁶ Hull, Proc. Am. Inst. Elec. Eng., 38, 1171 (1919); Science, 52, 227 (1920).

⁷ Bragg, Phil. Mag., [6] 40, 169 (1920).

⁸ Richards, This Journal, 45, 422 (1923).

ability to emulsify oil in water or much greater ability to emulsify water in oil, and further, that they should vary in these respects in the order given. The soaps of the trivalent metals aluminum and iron, should exhibit the greatest tendency to emulsify water in oil. The values in the several columns for the relative sizes of iron and aluminum atoms do not all agree, so that the relative emulsifying powers are not definitely indicated by these figures. In general, the values for the atomic diameters of the free metals are most reliable, since the values for the atomic diameters in compounds involve two variables which require some further consideration for their determination. On the other hand, there may be doubt that the elementary atom with its electrons occupies the same domain as does the atomic kernel in the compounds. However, there are enough uncertain factors involved to deter us from attempting to make any very fine distinctions on the basis of existing figures for atomic diameters.

To confirm the difference between the volumes of the metallic end of the molecule in Na and Ag soaps we made approximate determinations of the molecular volumes of their stearates as follows.

Molecular Volumes in Saturated Solutions

St	earate	Acetone	Benzene	Methyl alcohol	Av.
	Na	338	330		334
	Ag	309		291	300

There were known, previous to our own study of this subject, some facts which support this theory of the action of soaps. The soaps of the alkali metals are very effective in stabilizing oil-in-water emulsions, potassium soaps being more effective than sodium soaps. Magnesium soaps emulsify water in oil, 10 salts of the trivalent metals, aluminum and iron, are especially effective in reversing oil-in-water emulsions stabilized by soaps of the alkali metals. Emulsions of oil in water stabilized by sodium oleate are reversed by adding magnesium, aluminum, ferrous or ferric salts in amounts chemically equivalent to the sodium oleate used. 11

These facts encouraged us to undertake a more systematic study of the applicability of the theory here outlined. Stearates and oleates of the metals listed in Table I were used to prepare several series of emulsions, in which the concentrations of soap, the relative amounts of oil and water used and the degrees of shaking were varied for the different series, but composed of equivalent amounts of soaps in any one series. One liquid was always water, the other benzene, xylene or hexane.

Each group of emulsions was placed in a thermostat maintained at 23° and the time noted when each emulsion began visibly to break down.

⁹ Neunier and Maury, Collegium, 1910, 277; Chem. Zentr., 1910, II, 1416.

detailed reproduction is hardly necessary. The correspondence in all cases was far more closely in accord with the theory than we had dared to anticipate.

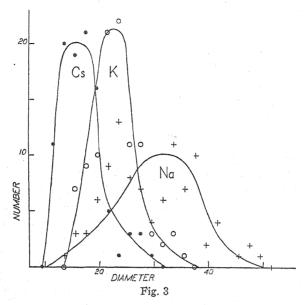

The results in these cases are also in accord with the rule that the external phase is the one which is the better solvent for the emulsifier. The soaps of the alkali metals are more soluble in water, the others more soluble in the non-polar liquid. The soaps of iron and aluminum have more symmetrical and less polar molecules and would, therefore, be expected to dissolve best in solvents of low polarity, while the alkali-metal soaps, consisting of a single chain with a highly polar end, cannot dissolve considerably in non-polar liquids but can, on the other hand, form clusters with the hydrocarbon chains in the interior, which can then dissolve "colloidally" in water.

If the orientation theory is correct, the different degrees of curvature natural to films of different soaps should yield drops of different sizes. Since the shaking would never produce drops of uniform size in any emulsion, it was necessary to determine the distribution of a large number of drops between different size intervals. (To take the mean size would obviously give abnormal weight to the occasional very large drops.) A micrometer microscope was used, and the diameter of all drops in the field measured, the field being altered often enough to get a total of 100 drops. The operator did not know which emulsion he was measuring until after he had finished.

Four different series of emulsions with cesium, potassium and sodium stearates were thus measured, the conditions in all series being identical except for the kind of soap used. Table III and Fig. 3 represent the results with one series. The size intervals are represented in scale divisions of the microscope micrometer, of which $60~{\rm div.}=0.01~{\rm mm.}$ The other series showed a similar displacement of the maxima, although due to differences in shaking, etc., among the different series, the soap did not yield the same maximum each time.

The flatness of the curve for sodium stearate in Fig. 3 evidently has no significance in view of the relatively small number of drops counted. In the other series no such marked difference occurred.

It is evident from these data that the cesium soap gives the smallest drops and the sodium soap the largest, so that the curvatures of the films actually differ in the predicted direction and, therefore, support the theory.

Many powdered solids have been shown to be capable of stabilizing emulsions.¹² It seems to be possible to account for the type of emulsion

Table III

produced by the following hypothesis. It is obvious, first, that the powder must collect at the interface in order to be effective. Now, this will occur

¹² Compare Pickering, J. Chem. Soc., 91, 2010 (1907); Kolloid Z., 7, 11 (1910). Sheppard, J. Phys. Chem., 23, 634 (1919). Schlaepfer, J. Chem. Soc., 113, 522 (1918). Moore, This Journal, 41, 940 (1919).

only when the solid is wetted by both liquids, with a finite angle of contact of the interface with the solid. In general, one liquid will wet the solid better than the other, as represented in Fig. 4, so that the particles will be drawn more largely into the former. If there are enough solid particles to fill the interface the tendency of the interface to contract will cause it to bend, as shown in Fig. 4, in the direction of the more poorly wetting liquid, which makes it easy for the latter to become the enclosed phase. Of course, a solid, in order to behave in this way, must be easily dispersed in the outer liquid, its particles not tending to agglomerate therein or to stick together when serving as protective armor for emulsified drops. One should, therefore, be able to predict whether or not a given solid powder can stabilize an emulsion, and also which liquid will become the

dispersed phase, by noting the angle of contact of the interface with the solid. Data upon this point are not abundant but seem to be altogether confirmatory, and a microscopic examination of an emulsion of water in benzene stabilized by lampblack confirmed the picture given in Fig. 4.

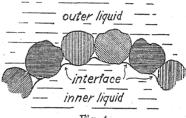

Fig. 4

We suggest that this picture may serve to explain the Bancroft rule that a colloid emulsifier causes the phase in which it is soluble to be external. A colloidal particle with only a few polar groups upon it would remain largely in the oil phase and vice versa, so that the natural curvature of the surface may be determined in much the same way as with powdered emulsifiers.

Summary

- The present status of the theory of emulsification has been outlined.
- The types and relative stabilities of emulsions formed by the aid of various soaps have been explained by the aid of the theory of orientation of the soap molecules in the interface.
- 3. The curvature of the film of soap adsorbed at the interface is more convex toward the water, yielding more stable emulsions of the oil-enclosed type, the larger the metal atom in the soap.
- 4. As the number of hydrocarbon chains attached to a single metallic atom increases (with the valence of the metal) the curvature is reversed, becoming strongly convex towards the oil phase with soaps of the trivalent metals, aluminum and iron, which yield the most stable emulsions of water in oil.
- 5. Experimental data upon the type and relative stabilities of emulsions of various liquids with water show that the transition from the most stable oil-enclosed to the most stable water-enclosed emulsion for both stearates

and oleates follows the order: cesium, potassium, sodium, calcium, silver, magnesium, zinc, aluminum, iron. This order is in accord with the valences and atomic diameters of the metals, as interpreted by the orientation theory.

6. It is suggested that the type of emulsion produced by a solid powder is determined by the angle of contact of the interface with the solid. In order for the powder to remain in the interface the angle must be finite, and unless the angle is 90°, the interface will be on one side or the other of the points of contact of the particles, and its tension will cause the film to be concave on that side.

DISPLACEMENT OF METALS FROM SOLUTIONS OF THEIR SALTS BY LESS ELECTROPOSITIVE ELEMENTS

I. THE REPLACEMENT OF SODIUM AND POTASSIUM BY MAGNESIUM AND ALUMINUM

By F. W. BERGSTROM¹

RECEIVED JUNE 22, 1923

Introduction

Franklin² found that a solution of potassium amide in liquid ammonia reacts readily with magnesium to form an opaque blue solution, which disappears within a few hours leaving a precipitate of the sparingly soluble potassium ammono-magnesiate, Mg(NHK)₂.2NH₃.³ During the preparation in an analogous manner of potassium and sodium ammono-aluminates the author observed the production of similar intermediate blue solutions. The present work, which was undertaken primarily for the purpose of accounting for the phenomena observed, and of establishing the equations for the reactions, is a portion of a general investigation dealing with the action of potassium and potassium amide upon the elements.

- ¹ National Research Council Fellow.
- ² Franklin, This Journal, 35, 1463 (1913).
- ³ Potassium and sodium amides are bases of the ammonia system, and behave in this solvent just as potassium and sodium hydroxides behave in water. Thus an aqueous solution of potassium hydroxide dissolves aluminum and zinc to form, respectively, potassium aquo-aluminate and potassium aquo-zincate, while a liquid ammonia solution of potassium amide dissolves aluminum to form a potassium ammono-aluminate, and reacts with zinc to form a sparingly soluble potassium ammono-zincate. Potassium ammono-magnesiate, on the other hand, has no analog in the water system, because the much greater solvolytic power of water relative to that of ammonia renders its existence impossible. Reactions thus occur in ammonia that cannot take place in water. For a further explanation of the ammonia system of acids, bases and salts, see Am. Chem. J., 47, 285 (1912); Proc. Eighth Int. Cong. Appl. Chem., 6, 119 (1912).

Discussion of the Reactions

The alkali and alkaline earth metals dissolve abundantly in liquid ammonia, yielding intensely colored blue solutions, which on concentration acquire a beautiful coppery luster. This behavior is characteristic of solutions of these elements alone, and so may be regarded as a positive test for their presence. Magnesium, if its surface is perfectly clean, dissolves to a slight extent in liquid ammonia, the saturated solution being light blue and readily transparent. Amalgamated aluminum does not dissolve under ordinary conditions, but might be expected to do so to a much less extent than magnesium if the surface were continually kept clean and free from amide as, for instance, by the action of a solution of sodium or potassium amide.

It is plain, therefore, that the opaque blue solutions obtained by the action of potassium amide on magnesium and aluminum, and of sodium amide on aluminum, must contain free alkali metal, for the strong color cannot possibly be due to either of the less electropositive elements. As a further and confirmatory test, these solutions, when evaporated almost to dryness, were found to assume the familiar coppery color characteristic of concentrated solutions of the alkali metals. After complete removal of the solvent, rather imperfect crystals of sodium or potassium were found to be deposited upon the walls of the reaction tube.

Kraus⁴ has shown that dilute solutions of the alkali metals in liquid ammonia conduct the electric current in the same manner as ordinary salts. The positive carrier is the sodium ion, Na⁺, while the negative carrier is the solvated negative electron, which may be represented by the symbol e⁻. The conductance curve in these regions is similar in form to the curves obtained with solutions of the common salts, approaching asymptotically a limiting value as the dilution increases.⁵

In view of these facts one should expect dilute solutions of the alkali metals to exhibit salt-like properties in other respects. In fact, Kraus⁶ has shown that the following metathetic reaction readily takes place because of the low solubility of one of the products, calcium chloride, in liquid ammonia: Ca (dslvd.) + 2KCl (dslvd.) = CaCl₂(ppt.) + 2K (dslvd.).

Magnesium⁷ is slightly soluble in ammonia, while aluminum probably dissolves under the proper conditions to a much less extent. Accordingly when either of these metals is treated with sodium or potassium amide, most of its ions are removed from solution by formation of the very slightly soluble magnesium or aluminum amide, and we have a virtual

- 4 Kraus, This Journal, 43, 749 (1921), and previous articles.
- ⁵ At a concentration above about 0.5 N, metallic conduction causes the curve to rise rapidly, a saturated solution conducting the current as well as many metals.
 - ⁶ Kraus, ibid., 44, 1224 (1922).
 - ⁷ Cottrell, J. Phys. Chem., 18, 96 (1914).

metathesis, which may be represented by the equations: $Mg + 2KNH_2 \longrightarrow Mg(NH_2)_2 + 2K$; Al + $3NaNH_2 \longrightarrow Al(NH_2)_3 + 3Na$.

In view of the slight solubility of both magnesium and aluminum, and in view of the fact that their amides cannot be completely insoluble, although, being weak bases, they must be but very slightly ionized in solution,⁸ it is necessary to assume an equilibrium to exist. This is being continually displaced toward the right because of the interaction of the alkali metal solutions with the solvent, in which process magnesium and aluminum play the part of catalytic agents: $3K + 3NH_3 \longrightarrow 3KNH_2 + \frac{3}{2}N_2$; or $3Na + 3NH_3 \longrightarrow 3NaNH_2 + \frac{3}{2}H_2$.

Aluminum and magnesium amides are both amphoteric in their properties and therefore react with the excess of potassium or sodium amide present to give the ammono salts finally obtained. In this manner aluminum and magnesium ions are practically completely removed from solution and the equilibrium is further displaced toward the right. The complete equations for the formation of sodium ammono-aluminate may then be written: Al + $3NaNH_2 \longrightarrow Al(NH_2)_3 + 3Na$; Al $(NH_2)_3 + NaNH_2 = Al(NH_2)_2NHNa.NH_3$; $3Na + 3NH_3 = 3NaNH_2 + \frac{3}{2}H_2$; and for the formation of potassium ammono-magnesiate: $Mg + 2KNH_2 \longrightarrow Mg(NH_2)_2 + 2K$; $Mg(NH_2)_2 + 2KNH_2 \longrightarrow Mg(NHK)_2.2NH_3$; $2K + 2NH_3 \longrightarrow 2KNH_2 + H_2$.

In view of the relative rapidity of formation of potassium ammono-aluminate and magnesiate, and of sodium ammono-aluminate according to the above type equations, it is probable that the equilibria of which the first equation is an example rest far over on the right hand side. In the first example above, sodium amide has a solubility of approximately 1 g. per liter, ^{8a} yet the blue solution obtained on interaction with aluminum is quite opaque and contains sodium in fairly high concentration.

Evidence for the intermediate formation of aluminum amide has been obtained during a previous study of the action of potassium amide on aluminum. Aluminum, although a very reactive metal, is quickly covered in air with an adherent protective coating of oxide which hinders further action. Consequently in order that reaction with the alkali metal amides might take place at all, it was necessary to amalgamate the surface. It will be shown later that the mercury plays no essential part in the course of the reactions, although it may in some measure increase the velocity.

This work suggests that the reactions between potassium or sodium hydroxide and aluminum may partially take place in an analogous manner,

⁸ Even the relatively strong ammono bases, sodium and potassium amides, are ionized only to a small extent in solution. Nevertheless, aluminum and magnesium amides are weak enough to exhibit amphoteric properties toward them. Kraus, "Properties of Electrically Conducting Systems," 1922, p. 59. American Chemical Society Monograph, Chemical Catalog Co.

that is, the evolution of hydrogen may be due to a secondary action of potassium or sodium on water rather than to a direct replacement of the hydrogen of the hydroxyl group. Certain experiments already carried out favor this view, but further discussion will be reserved for a future paper.

Action of Solutions of Sodium and Potassium on Aluminum

Potassium⁹ and sodium ammono-aluminates are formed by the action of solutions of the alkali metals alone on amalgamated aluminum. It seems probable that the potassium or sodium is first converted to amide by the combined catalytic action of the aluminum and mercury, and this in turn reacts as previously described. It was found, curiously enough, that the formation of sodium ammono-aluminate by either of the methods mentioned was two to three times more rapid than the formation of the potassium analog, undoubtedly because of difference in the rapidity of the initial stage of the reaction.

Potassium amide, due to its superior solubility, probably reacts at first much more rapidly on aluminum, quickly coating the amalgamated areas over with a thick and relatively adherent layer of aluminum amide and preventing for the time being direct contact between portions of the metal and the solution. Experiments^{9a} with potassium amide and slightly amalgamated aluminum have shown that the amalgamated surfaces may be covered up so as to stop the reaction completely, although only temporarily, causing a periodic production and disappearance of the blue potassium solution. With sparingly soluble sodium amide, aluminum amide is undoubtedly formed at a slower rate, and thus has no tendency to form a retarding layer, that is, contact exists between the active areas of the metal and solution at all times. The resultant reaction is, therefore, more rapid.

That the mercury is inert, aside from possible catalytic effects, is shown in the two following experiments.

- (1) A piece of sheet aluminum was well amalgamated in a liquid ammonia solution of mercuric iodide, ¹⁰ washed with the same solvent, and then sealed up in one leg of a two-legged reaction tube. ¹¹ The other leg contained a few tenths of a gram of sodium. Ammonia was distilled into the reaction tube, a portion of the sodium solution was poured upon the aluminum and allowed to remain until the mercury of the amalgam was saturated, after which the metal strip was washed and allowed to remain in contact with fresh solvent for a day. No evidence of the formation of sodium ammono-aluminate could be obtained, even after the mercury had been treated again with sodium.
- (2) A moderately concentrated sodium amalgam was prepared by agitating a solution of sodium in liquid ammonia with mercury in a three-legged reaction tube. This together with the ammonia was then poured upon a small, well-amalgamated slab of

³ (a) Unpublished work of the Author. (b) See C. A., 16, 3822 (1922).

¹⁰ To prevent oxidation.

¹¹ See Expt. 4.

aluminum prepared as in the preceding experiment. At the end of $4^{1}/_{2}$ months no sodium ammono-aluminate had been formed.

Sodium Ammono-Aluminate

Sodium ammono-aluminate, obtained by either of the methods mentioned, is readily soluble in liquid ammonia at ordinary temperatures, and may be obtained in the form of small white needles by cooling a moderately concentrated solution to $-40^{\circ}.^{12}$ The solubility at 0° is only a little less than at room temperature. Curiously enough, large crops of blunt prisms were obtained in two cases by cooling (in ice water) the solution obtained immediately after the disappearance of the blue color of the sodium. After these solutions had stood for a day, only the small needles, previously described, were obtained when the liquid was cooled to -40° . The existence of two crystalline modifications of this salt is not surprising in view of the fact that aluminum cyanide behaves in a somewhat similar manner. 9a

Sodium ammono-aluminate when dried in a vacuum at either -33° or room temperature corresponds in composition to $Al(NH_2)_2NHNa.NH_3$, $Al(NH_2)_3.NaNH_2$ or $Na[Al(NH_2)_4]$. When heated in a vacuum it melts near 90° with a large increase of pressure, giving off one molecule of ammonia and forming $Al(NH_2)_2.NHNa$, a solid of the nature of a glass, and possessing no crystalline structure.

Water reacts very vigorously with either of the above compounds, a great deal of heat being developed. The resulting products of hydrolysis are for the most part soluble in the water introduced into the reaction tube. Hydrochloric acid then reacts with this solution of sodium aquo-aluminate and with the remaining precipitate to form aluminum, ammonium, and sodium chlorides.

Experimental Part

The general methods used for the preparation of compounds in liquid ammonia solution and their subsequent analysis have been described in previous articles.¹³

In this work analyses were made on aliquot portions of the hydrochloric acid solution of the specimen.

Preparation 1.—In one leg of a two-legged reaction tube were placed 0.35 g. of sodium and an excess of commercial sheet aluminum, the other leg remaining clean and empty for subsequent crystallization of the aluminate. The sodium was completely converted after 24 hours into a colorless solution of sodium ammono-aluminate, which was then separated from a small quantity of residue by decantation into the other leg. On cooling to 0°, a large crop of blunt thick needles was obtained, although only the fine needles could be isolated in the succeeding experiments. When this stood for a day.

¹² In an open ammonia bath.

¹³ This Journal, **27**, 831 (1905); **29**, 1694 (1907); **35**, 1460 (1913). *J. Phys. Chem.*, **15**, 915 (1911); **16**, 694 (1912).

partial ammonolysis took place with the deposition of some amorphous white precipitate. Accordingly, the solution was merely evaporated to dryness and then analyzed.

. Analyses. Subs., dried in a vacuum at -40° (1–2 mm.), 1.3055 g. Wt., dried in a vacuum at room temperature, (1 mm.), 1.3053 g. One-fifth gave 0.1650 g. of sodium sulfate; two-fifths gave 0.2346 g. of Al₂O₃.

Preparation 2.—The reaction between 0.34 g. of sodium in the form of amide with an excess of pure amalgamated aluminum was complete at the end of a day. The resulting salt was crystallized once by cooling the moderately concentrated solution in an open liquid-ammonia bath, and ammonia of crystallization at —33° was determined by the method outlined by Franklin. Unfortunately, a small quantity of sodium amide lodged in the stopcock tube and could not be removed, helping to make the sodium analysis run a little high. The analytical results for the first and fourth experiments are more satisfactory, even though impure aluminum was used. The larger surface of metal exposed in these cases undoubtedly accounts for the facts.

Analysis. Subs., dried in a vacuum at -33° , 0.9335 g. Wt., dried in a vacuum at room temperature, 0.9323 g. Two-fifths gave 0.1633 g. of Al₂O₅; one-fifth gave 0.08989 g. of nitrogen; one-fifth gave 0.0813 g. of Al₂O₃ and 0.1026 g. of NaCl.

Preparation 3.—The preparation was carried out as in Expt. 1, using, however, small pieces of pure amalgamated aluminum. The sodium solution was changed to sodium ammono-aluminate within a day. The product was crystallized twice at —40° without the appearance of insoluble ammono basic residues. (Compare Expt. 1.) On heating in a vacuum, the salt melted at 85–90° and on continued evacuation finally solidified to a voluminous froth.

Analysis. Subs., dried in a vacuum at room temperature, 0.7736 g. Wt., heated in a vacuum at 110°, 0.6528 g. (Probably a little overheated.) One-quarter gave 0.06929 g. of nitrogen; one-quarter gave 0.0879 g. of Al₂O₃ and 0.1032 g. of NaCl.

Preparation 4.—This experiment was performed primarily to see whether the mercury of the amalgam took any essential part in the reaction. After completion of the tests described previously in this article, the sodium solution was poured upon the aluminum, and allowed to react with it. The salt was crystallized twice at 40°, then dried in a vacuum at room temperature and 105°.

Analysis. Subs., dried in a vacuum at room temperature, 1.0004 g. Wt., dried in a vacuum at 105°, 0.8513 g. One-quarter gave 0.1145 g. of Al₂O₃ and 0.1274 g. of NaCl; one-quarter gave 0.09206 g. of nitrogen. One-quarter gave 0.1147 g. of Al₂O₃.

SUMMARY OF ANALYSES

Dried in a	vacuum	at —33°	or room	tempe	rature.	Heated	in a va	icuum a	above 1	00°

Na	20.2	20.5	21.6	21.0	20.0	Na	23.7	24.9	23.6	

In conclusion the author wishes to thank Dr. Charles A. Kraus for his kind and helpful interest in this work.

Summary

1. Sodium amide and amalgamated aluminum react to form a definite crystalline compound, sodium ammono-aluminate, to which any one of the following formulas may be given: Al(NH₂)₂NHNa.NH₃, Al (NH₂)₃.NaNH₂,

or Na[Al(NH₂)₄]. This compound loses one molecule of ammonia on heating in a vacuum above 90°. The equations for the reaction have been shown to be Al + 3NaNH₂ \longrightarrow Al(NH₂)₃ + 3Na; Al(NH₂)₃ + NaNH₂ = Al(NH₂)₂NHNa.NH₃; 3Na + 3NH₃ = $\frac{3}{2}$ H₂ + 3NaNH₂.

The action of potassium amide on amalgamated aluminum and on magnesium are analogous in character. An explanation is given which depends upon the fact previously pointed out by Kraus that dilute solutions of the alkali metals in ammonia are salt-like in character. The initial stages may be regarded as metatheses, although actually involving equilibria which suffer continual displacement because of secondary reactions.

2. A solution of sodium in liquid ammonia reacts with amalgamated aluminum to form the same sodium ammono-aluminate described above. Sodium amide is probably first formed, and this in turn reacts according to the equations given. The mercury of the amalgam does not play an essential part in the reaction.

Worcester, Massachusetts

[Contribution from the Chemical Laboratory of Johns Hopkins University]

THE DIELECTRIC CONSTANTS OF ORGANIC LIQUIDS AT THE BOILING POINT

By F. V. Grimm and W. A. Patrick Received June 29, 1923

The following study was undertaken with the idea of finding some relationship between the dielectric constant of liquids and other physical properties. It was thought that the dielectric constant would be found to be related to those properties of liquids that depend upon the force of molecular attraction, namely, latent heat of vaporization, surface tension, etc. That such relationships do exist is shown by the parallelism that is exhibited in the case of organic homologs. 1,2,3 The conclusion was, however, reached that no simple relationship exists between the dielectric constant and the latent heat of vaporization although in the case of closely related liquids there was unmistakable evidence to show that the contrary is true. Walden4 connects several physical properties of liquids with the following function of the dielectric constant: $\frac{D.C.-1}{D.C.+2}$, $\frac{1}{\delta}$ which according to the Clausius-Mossotti theory involves the volume actually occupied by the molecules. All of these relations give different values for associated and non-associated liquids. Walden uses values of surface tension, latent heat of vaporization, etc., at the boiling temperature, while the values of

¹ Hesehus, Physik. Z., [2] 750 (1900).

² Campbell, "Modern Electrical Theory," Cambridge University Press, 1913.

³ Obach, Phil. Mag., [5] 32, 113 (1891). ⁴ Walden, Z. physik. Chem., 70, 569 (1910).

the dielectric constant and density are taken at 20°. This procedure was justified on the ground that according to the Clausius-Mossotti theory the above function is independent of the temperature. However, Katz⁵ has shown that the function in question is not independent of the temperature but gives variations that are especially marked with liquids of high dielectric constant.

If we accept the classical electronic theory of dielectrics, we arrive at the following picture: the dielectric constant is due to a displacement of a certain number of electrons by the electric field. The following relation is given by Lorentz and Lorenz as expressing the connection between the dielectric constant and the number of displaced electrons N, the charge on an electron e and the force f due to the positive charge of the molecule which tends to restrain the electron from leaving.

D.C. =
$$1 + \frac{4\pi Ne^2}{f - \frac{4}{3\pi} Ne^2}$$

Thus we have two unknown quantities, N and f; N is probably proportional to the number of molecules and therefore to the density of the substance, but little or nothing is known of the force f. It is probable that this force is connected with the force of molecular attraction, and hence the relation that is sought between the dielectric constant and surface tension or latent heat of vaporization.

It has been suggested that more constant relations might be obtained if values of the dielectric constant were taken at the boiling temperature. This has been attempted by Turner⁶ with a few liquids by calculating the dielectric constant at the boiling point from the values at 20° and the temperature coefficient. However, the dielectric constant is not a linear function of the temperature, as has been shown by Katz and others, and in certain cases behaves in a most irregular manner. For example, Tangl⁷ has shown that the dielectric constant-temperature curve for ether is first convex and then concave toward the temperature axis. For this reason we have therefore undertaken to determine directly the dielectric constant at the boiling temperature. Thirty-five organic liquids in all were measured, and the results should be of the greatest value to anyone interested in the theory of dielectrics.

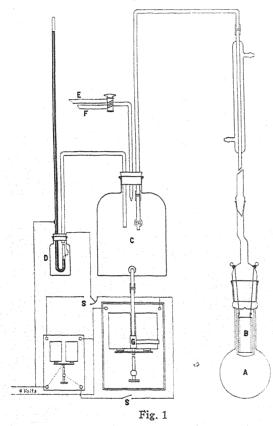

Measurements of the dielectric constant at the boiling point are not easily made due to the troublesome effect of conductivity, which increases very rapidly with increasing temperature. The method used in the following measurements has enabled us to work with liquids having a conductivity less than that of pure water, without sacrificing the accuracy of the results.

⁵ Katz, Z. physik. Chem., 19, 94 (1896).

⁵ Turner, J. Chem. Soc., 107, 276 (1915).

¹ Tangl, Drude's Ann., 10, 748 (1903).

Apparatus.—The method employed was a modification of the Nernst bridge method which has been described in detail by King and Patrick.⁸ With the exception of a different arrangement of the dielectric cell, very few changes in the apparatus were necessary. The dielectric cell consisted of two coaxial platinum cylinders sealed in a fixed position by small plugs of glass at both ends. This condenser was suspended in the liquid by means of two platinum wires. The size of the cylinders of cell No. 1 were 6.3×1.9 cm., and 6.3×2.2 cm. With this cell we were able to read changes of about forty in the dielectric constant. In using cell No. 2, in which the plates were closer together (the outer

cylinder was 2.1 cm. in diameter) the same change on our reference scale corresponded to a change of about ten in the dielectric constant. This latter cell could only be used with non-associated liquids or at least with liquids of low conductivity.

The liquid dielectric was brought to its boiling temperature by being immersed in a bath of its own vapor at a pressure of 760 mm. This pressure was held constant to within less than 1 mm. by means of a pressure regulator. The boiling flask (A) in Fig. 1 had a capacity of about 250 cc. and the dielectric cup 50 cc.; consequently, the minimum amount of liquid required for a determination was approximately 150 cc. The glass cup was suspended within the neck of the flask by means of four prongs, which allowed the vapor to pass around the cup into the condenser above. The cell (B) was suspended within this cup by two platinum wires sealed in at the top of the ground-glass stopper. Care had to be taken to prevent superheating of the

vapors surrounding the dielectric cup. The reading was taken when the liquid in the cup had reached such a temperature that an occasional bubble would rise from the bottom. This very slow boiling did not affect the location of the minimum, since the bubble did not pass between the two plates. This was found to be the criterion of the correct boiling temperature by a preliminary experiment in which the platinum cell was replaced by a standard thermometer and the boiling temperature of water observed.

By means of a slight bend in the tube leading from the flask to the condenser, it was possible, by giving the condenser a half turn in the ground-glass joint, to cause the refluxing liquid to drop directly into the cup or to run down the side of the flask as desired. This arrangement was to allow for refilling the cup in case an appreciable amount

⁸ King and Patrick, This Journal, 43, 1835 (1921).

of the liquid had evaporated before the final reading was obtained. The liquid was never allowed to reflux into the cup while a bridge reading was being taken, since this resulted in a shifting of the minimum due to the cooling effect of the condensed liquid.

The top of the condenser was connected to the equalizing bottle C of the manostat by means of glass tubing. The liquid was protected from the moisture of the air by a tube containing phosphorus pentoxide connected inside the bottle C. At the top of the equalizing bottle was a glass tube which could be connected either to the compressed air line or to a water suction pump at E and F. A third tube was connected with a bottle D containing the open end of a barometer. The mercury valve G of the gas regulator was attached to the bottom of the equalizing bottle.

The mercury in the barometer was so adjusted that when contact was made with the platinum wire sealed in at the lower limb, the height was exactly 760 mm. The barometer was calibrated both by determining the pressure at which pure water boiled at 100° and also by comparison with a standard barometer. When the atmospheric pressure was less than 760 mm., the system was connected with the pressure lines, and the electric connections were made as shown in the drawing. Thus when the circuit was broken between the mercury meniscus and the platinum point, the valve G opened and allowed the air to escape. By careful regulation of the air entering and leaving, the fluctuations of the mercury meniscus were reduced to less than 0.5 mm. In the case that the atmospheric pressure was greater than 760 mm. the system was connected to the reduced-pressure sides, and the second relay thrown in by means of the switches S and S'. We were therefore able to bring the pressure to the value 760 mm. under all conditions of atmospheric pressure. The two relays were actually enclosed in a double walled box not shown in the drawing. This was to prevent the noise of the relays from interfering with the location of the minimum on the bridge.

Calibration.—The calibration of the scale was made by using different standard liquids whose dielectric constants at room temperature were accurately known. The temperatures of the standard liquids were ascertained by allowing them to come to the temperature of the room in contact with a standard thermometer. The temperature was taken immediately before and after the bridge reading was made. The values of the known dielectric constant when plotted against the scale reading of the measuring condenser gave an exact straight line as shown by King and Patrick. This curve was plotted on a large sheet of paper (100×150 cm.) accurately coördinated in millimeters from which the values of the dielectric constant at the boiling temperature were taken. The standard liquids, the values of the dielectric constant at 18°, and the temperature coefficients are given in Table I.

Table I
DIELECTRIC CONSTANTS OF STANDARDS

Liquid	D. C. at 18°	$\frac{1}{D} imes \frac{\mathrm{d}D}{\mathrm{d}T}$	Observer
Benzene	 2.288	0.0007	Turner
Chloroform	 4.95	.00376	Walden
Aniline	 7.115	.00351	Katz and Turner
o-Nitrotoluene	 27.71	. 0055	Turner
Nitrobenzene	 36.45	.005	Turner

The scale of the measuring condenser was calibrated at frequent intervals during the course of this work and was tested with one or more standard liquids before and after each measurement.

Purification of Liquids

Benzene.—c. p. Benzene was shaken repeatedly with sulfuric acid until the latter was no longer darkened. It was then shaken with mercury, washed with water, dried

and distilled. After two fractional crystallizations, it was dried over metallic sodium and distilled. A constant-boiling fraction was preserved.

Chloroform.—After standing for several weeks over coned. sulfuric acid, the chloroform was washed repeatedly with water, dried over calcium chloride and fractionated. A 500cc. fraction which distilled within 0.03° was preserved.

Aniline.—c. P. Aniline was twice fractionally distilled, then crystallized, dried with potassium hydroxide and again distilled. A 400cc. fraction boiling within 0.15° was taken.

o-Nitrotoluene.—A c. p. sample was dried with calcium chloride, fractionated once by distillation and twice by crystallization, and finally redistilled. A 300cc. fraction boiling within less than 0.1° was taken.

Nitrobenzene.—c. p. Nitrobenzene was dried with phosphorus pentoxide. A fraction boiling at 212.0-212.08° (770 mm.) was used.

The standard liquids were kept in the dark in a desiccated atmosphere under a bell jar. They were several times redried and redistilled during the course of this work.

The liquids investigated were purchased in the purest possible condition and were further purified with suitable reagents, dried, and finally subjected to one or more fractional distillations, either at normal or reduced pressures. A very efficient all-glass still, consisting of six sections of a Young "evaporator," was used. The fractions taken, boiled within a small fraction of a degree of the correct temperatures, except of those of quinoline and acetonitrile. Quinoline which had been separated from any contained nitrobenzene by steam distillation and from aniline by diazotization and subsequent steam distillation, extracted with ether, distilled, and dried over potassium hydroxide, was subjected to several fractional distillations. Nevertheless, a constant-boiling fraction could not be obtained. The fraction finally used, consisted of about 200 cc., boiling between 237.3° and 238.5° (uncorr.).

Acetonitrile was washed with water, salted out with potassium hydroxide, dried and fractionally distilled several times with phosphorus pentoxide. The fraction used boiled at 80.1–81.3°. The liquid in the dielectric cell, however, probably represents a much better sample, since the first portion only was used in the cell.

The impurity which gave by far the most trouble was water. As is well known, it is very difficult if not impossible to remove the last traces of water from certain alcohols, ketones, etc., and the presence of a very small amount will increase the conductivity of these liquids to such an extent that a minimum on the bridge cannot be obtained. Even when the liquid had a very small conductivity at room temperature, it was often the case that at the boiling temperature the conductivity was so great that it required the maximum conductance of the shunt resistances to counterbalance it.

Fleming⁹ points out that there are two kinds of conductance: The first follows Ohm's law and is due to a large extent to impurities. This conductance can be greatly reduced if not eliminated entirely by proper purification and drying. The other conductance which does not obey Ohm's law, but is proportional to the frequency of the alternations, is caused by a slipping of the displaced electrons. This latter conductance increases very rapidly with the temperature, and because of this fact accurate measurements of the dielectric constant of certain liquids at the boiling temperature cannot

Fleming, Proc. Phys. Soc., [2] 23, 117 (1911).

be made. The values for acetonitrile, benzyl cyanide, ethylene chlorohydrin and nitromethane reported below have been rendered less accurate because of this conductivity.

The values of the dielectric constant at room temperature are included in Table II merely for comparison. They are reported in the first place only since no particular care was taken in their determination. The reason

Quinoline	5.05	.02	238	9.00	25

for this was that the temperature could not be determined accurately without exposing the liquids to the moisture of the air, which would result in a much higher conductivity and in certain cases would have prevented measurement being made at the higher temperature. It may be mentioned

here that it was necessary to distil several of the alcohols, ketones and nitriles directly into the flask A in order to prevent them from being contaminated with the moisture of the air.

When cell No. 1 was used, each millimeter of the scale division of the measuring condenser represented a change in the dielectric constant of nearly 0.02, and with cell No. 2 each scale division corresponded to a change in dielectric constant of 0.01. When the conductivity was not greater than that which could be balanced out with the shunt resistance filled with Mangani solution, ¹⁰ the readings could be checked to within less than one division.

In case the conductivity was greater than this, it was necessary to add potassium chloride to the Mangani solution in the shunt resistance tubes. As a consequence the greater part of the current was shunted around the condensers and the result was that the minimum became very much fainter. This was the case with the 4 liquids in Table II where the dielectric constant was determined to within only 0.1 of a unit. In no case are values reported which could not be checked within 5 scale divisions. The few liquids worked with which could not be determined with this precision were methyl alcohol, which had too high a conductivity and showed anomalous absorption, ethyl sulfate and monochlorohydrin.

Discussion of Results

It may be stated at the outset that no improvement in the empirical formulas of Walden and others was shown after the substitution of our results for the dielectric constant at the boiling point. The agreement was no worse than that obtained by Walden, but on the other hand it was no better. From this fact one may be inclined to agree with Walden that the particular function of the dielectric constant employed by him was independent of the temperature. However, it is our belief that no generalization connecting the dielectric constant with other properties of liquids has been formulated that is worthy of serious consideration. There is hardly another property of liquids which at a corresponding temperature exhibits such wide variations as the dielectric constant. The primary object of this paper is to provide accurate data which may serve as a basis for a physicochemical generalization regarding the dielectric constant of liquids.

In those expressions which contain the Clausius-Mossotti relation, the difference in the values when applied to associated liquids is probably due to the fact that the expression, $\frac{D.C.-1}{D.C.+2}$, is not a correct measure of the

volume actually occupied by the molecules. Furthermore, the assumption made by Lorentz that the molecules around a given molecule act with equal

 10 Mangani solution is prepared by dissolving 121 g. of mannite, 41 g. of boric acid and 0.06 g. of potassium chloride in one liter of water. This solution has a specific conductivity of 0.9 \times 10 $^{-\prime}$ and practically no temperature coefficient.

force upon it does not seem to be entirely justifiable. According to recent theories of the structure of the molecule, certain portions have stronger external fields than others. Such a theory is used by Langmuir in his explanation of surface energy, adsorption, etc. Likewise, the dipole theory of Debye¹¹ leads to the same conclusion. This theory attempts to explain the electrical properties of dielectrics on the assumption that in addition to the free and elastically bound electrons, there are electrical doublets or dipoles whose strength does not depend on the electric field in which they are situated. These dipoles are assumed to be the result of dissymmetry in the molecule. The theory cannot be said to be in its final form, although a recent modification by Gans¹² seems to hold great promise.

When we arranged liquids according to their value of the expression (D.C.-1)/(D.C.+2) it was found that the order did not agree with the known solubility relations or chemical properties. On the other hand, it was found by trial that the expression $\frac{(D.C./\delta)-1}{(D.C./\delta)+2}$ gave results of some value.

We therefore decided to use this latter expression as representing the volume actually occupied by the molecules.

The application of the above idea may be illustrated by applying it as a correction to Dieterici's equation for the internal heat of vaporization. Dieterici¹³ has shown that the empirical relation, $\lambda_i = CRT \log{(V_2/V_1)}$, where C is a constant, V_2 and V_1 are the specific volumes of the saturated vapor and liquid, respectively, and R is the ordinary gas constant referring to 1 g., holds over a wide range of temperature for normal or non-associated substances. When we substitute the free space of the molecules in the liquid state in place of V_1 , we obtain an equation similar to that of Bakker, ¹⁴ namely, $\lambda_i = CRT \log{(V_2/(V_1 - b))}$. We, however, set b equal to $\frac{(D.C./\delta) - 1}{(D.C./\delta) + 2}$

In Table III are given the values of the constant \mathcal{C} as calculated from the above equation. It is surprising to notice the constancy of \mathcal{C} even in the case of associated liquids. We do not claim that we are able to express exactly the actual volume occupied by the molecules in the liquid state, but some progress is indicated and it is predicted that further work along this line may reveal results of the greatest interest. A knowledge of the structure of liquids would certainly be of the utmost service in the elucidation of the many problems in the field of solutions, etc. It is interesting to note that the only liquids giving widely diverging values of \mathcal{C} are the ketones and compounds containing nitrogen.

Summary

The dielectric constants of 35 organic liquids have been determined at the boiling point under a pressure of 760 mm.

A method has been suggested for evaluating the volume occupied by the molecules in the liquid state.

The above idea was applied to Bakker's equation for the latent heat of vaporization.

THE IONIZATION OF SALT VAPORS

By Wendell M. Latimer Received July 11, 1923

A study of the energies of formation of the simpler chemical compounds seems to offer a promising method of investigating the problems of molecular structure; and now that data are available for the calculation of the heats of ionization of the vapors of the hydrogen and alkali halides, it is important to consider these heats from the standpoints of both the static and dynamic theories of atomic structure. The heats of ionization are also interesting in that they enable us to calculate the degree of ionization of these salt vapors and thus dispel any doubt as to their very slight ionization.

The heat of ionization of a salt vapor may be calculated from the heat of formation of the salt vapor from its elements in the state of monatomic vapors, the ionization potential of the metal and the electron affinity of the negative element. The corresponding equations for sodium chloride are:

$$Na + Cl = NaCl$$
 $\Delta H = -5.05 \text{ volt/equiv.}$
 $Na^{+} + E = Na$ $\Delta H = -5.12$
 $Cl^{-} = Cl + E$ $\Delta H = +3.9$
 $Na^{+} + Cl^{-} = NaCl$ $\Delta H = -6.25$

In order to obtain the heat of the first reaction the values tabulated by Wortenberg and Schulz¹ were used for the heat of formation of sodium chloride from metallic sodium and molecular chlorine,—99,000 cal., the heats of sublimation of sodium metal, 30,000 cal., and of sodium chloride, 48,000 cal., and the value of Trautz and Stackel² for the dissociation of the chlorine molecule into atomic chlorine, 71,000 cal. The change of the heat of the reaction with temperature is less than the experimental error in some of the data and has therefore been neglected. The value for the heat of the reaction in calories, namely, 116,500, has been converted to volt equivalents, since the spectroscopic data which we shall use are more commonly expressed in this unit.

The heat³ of the second reaction, 5.12 volts, is known accurately as the energy corresponding to the head of the (1s-mp) series of sodium. The electron affinity of chlorine, according to Franck's⁴ interpretation of the spectra of the halogens, is given by the head of the series converging at 3180. This value, 3.9 volts, is somewhat in doubt; however, it leads to a heat of

ionization of hydrogen chloride (see Table I) which is in agreement with the experimental value of Foote and Mohler.⁵

In a similar manner (1) the heats of formation from their elements as atomic gases, and (2) the heats of ionization of the hydrogen and alkali chlorides, bromides and iodides have been calculated and are given in Table I. The electron affinity of bromine, 2.9, and iodine, 2.6, and the other data for the alkali halides have been taken from the same sources as those for sodium chloride, except the values for the dissociation of molecular bromine, 42,000 cal., and molecular iodine, 35,000 cal., which are approximate values taken from the calculations of Lewis and Randall.⁶ For the heats of formation of hydrogen chloride, bromide and iodide from their elements as diatomic gases the values of Lewis and Randall have again been used: 22,000, 12,000 and 1500, respectively. The dissociation of hydrogen, 3.1 volts, is that given by Olsen and Glockler.⁷

Table I

Heats of Formation from Elements as Monatomic Vapors and Heats of Ionization in Vapor State

		H		A F	ī		A.	Ħ	
	Formation	Ionization]						1
HC1	-4.05	13.6	HBr	-3.0	13.6	HI	-2.4	13.3	
LiCl	6.1	7.6	LiBr	-5.6	8.1	LiI,	-4.4	7.2	
NaCl	-5.05	6.25	NaBr	-4.5	6.7	NaI	-4.0	6.5	
KC1	-5.3	5.7 -	KBr	-4.75	6.15	KI	-4.2	5.9	
RbCl	-5.4	5.7	RbBr	-4.75	6.05	RbI	-4.2	5.8	
CsCl	-5.4	5.4	CsBr	-4.8	5.8	CsI	-4.2	5.5	

It will be observed that for a given halide the heats of ionization are in the same order as the ionization potential of the positive atoms, and that, in general, the work of ionizing a halide from a positive ion is not much greater than that of removing the valence electron. It may also be observed that these compounds do not form, as is often stated, because of the greater affinity of the halide for the electron. Thus, hydrogen and chlorine combine in spite of the fact that it requires 13.54–3.9 or 9.64 volts to take the electron off the hydrogen and put it on the chlorine.

Ionization Constant for Sodium Chloride

The ionization constant for the reaction, NaCl = Na⁺ + Cl⁻, may be calculated from the relation: $-RT \ln K = \Delta H - T\Delta S$. For ΔH , the heat of ionization, we have found 6.25 volts or 144,000 cal. For ΔS , the entropy change of the reaction of 298 °K. and 1 atmosphere, the value 22.4 is obtained using for the entropy of Cl⁻ 36.3, and of Na⁺ 35.1, as given by the Sackur equation⁸ and for the entropy of sodium chloride 49.0, as given

⁵ Ref. 3, p. 186.

⁸ Lewis and Randall, "Thermodynamics," McGraw-Hill Book Co., 1923.

⁷ Olsen and Glockler, Proc. Nat. Acad. Sci., 9, 122 (1923).

⁸ Compare Lewis, Gibson and Latimer, This Journal, 44, 1008 (1922).

by the approximate equation of Latimer⁹ for the diatomic gases. Taking ΔC_p for the reaction as 2.5 cal./deg., ΔS_{1725} is 26.8 at the boiling point of sodium chloride. Then for the equilibrium constant at the boiling point, $-1725 \times 4.59 \log K = 144,000 - 1725 \times 26.8$, and for K we find 4×10^{-13} . The partial pressure of either of the ions in the vapor at 1725°K. and 1 atmosphere is then 6×10^{-7} atmospheres. In other words, sodium chloride vapor is ionized to about the same extent as liquid water at ordinary temperatures. Indeed, if we calculate in a similar manner the dissociation of sodium chloride vapor into atomic sodium and chlorine, we find this decomposition to be almost a hundred fold greater than the ionization. Using the same method as that employed for sodium chloride, the ionization constant of all the compounds in Table I may be determined. In every case the ionization would be found to be extremely small.

Heats of Ionization and Atomic Structure

The method which Born¹⁰ has used to calculate the energy of the crystal lattice for the alkali halides has been (1) to determine the field of force about an ion, and (2) from the field of force to calculate the energy of combination as due entirely to the change in electrostatic potential of the ions. We wish to consider the validity of this method in connection with the heats of ionization which have been given in Table I.

Spectroscopic data, as interpreted by the Bohr theory, seem at present to offer the only exact method of determining the field of force about an ion. The simplest case is, of course, the hydrogen ion; and here, from the completeness of Bohr's explanation of the hydrogen spectra, we may conclude that the field of force, up to a few tenths of an Ångström unit (10^{-8} cm.), corresponds exactly to the inverse square for a charge equal to, but of the opposite sign to that of the electron.

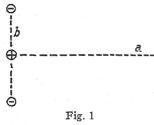

The fields of force for the more complicated ions are not so simple. However, even in these cases, considerable information can be gained from spectroscopic data. Thus, for lithium, the energy of the atom with the electron in the first external, circular orbit may be found from the head of the (2p-ms) series as 3.53 volts. The energy for the corresponding orbit of hydrogen, the 2_2 orbit, is 3.38 volts; and we may calculate from the Bohr theory that the radius of the orbit is 2.08 Å., and at that distance, the field about the lithium ion corresponds to an effective positive charge of 1.02. For the energy levels at greater distances the effective charge approaches unity very closely. For the interval between 2.08 Å. and the inner electrons, the field of force cannot as yet be determined. However, in order to get an approximate value for this field, we may calculate an average position of the two inner electrons in respect to the nucleus

⁹ Latimer, This Journal, 43, 818 (1921).

¹⁰ Born, Verb. Physik. Fes., 21, 13 (1919); 21, 679 (1919).

of 3 positive, Fig. 1, that would give an effective charge of 1.02 at a distance of 2.08 Å., along $a: 3-2 \times \frac{2.08^3}{(2.08^2+b^2)^{3/2}} = 1.02$. This gives b equal to 0.17 Å. Without attempting to attach more than a qualitative significance to the result, the curve for lithium in Fig. 2 has been drawn for the change in the effective charge as the ion is approached along the line "a." Actually, the effective charge must increase somewhat more rapidly than indicated by this approximate treatment.

Likewise, for sodium, we may calculate the energy of the electron in the first external energy level, the 3_8 orbit. In this case it is given by the head of the series at 12,274, and the energy is 1.515 volts. This value corresponds to a radius of 4.8 Å. and an effective charge on the kernel of 1.005 at that distance. If the electrons in the outer shell of the sodium ion were located in definite fixed positions, this value just obtained would serve as a very useful starting point to determine exactly the field at closer distances. At present, although we are confident that the field becomes

more positive closer to the ion, we are not in a position to determine it exactly.

Spectroscopic data are available for similar calculations for all of the alkali metals. However, in the heavier atoms, the first external orbit is out so far, as was the case for sodium, that the field is practically unity, and we are unable to judge the nature of the field closer to

the atom. As yet the spectra of the halides have not been worked out sufficiently to give any definite knowledge in regard to the fields of force about the negative ions. However, we may safely say that at a distance, a chloride ion, for example, acts as a unit negative charge, and at closer distances the sign of the field changes to positive.

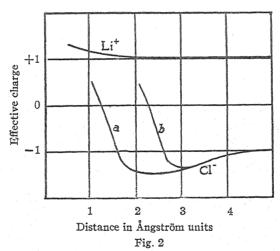

Now let us consider the problem of determining the heats of ionization from the fields about the ions. From our knowledge in regard to the quan-

We may also make use of the assumption that the orbits of the two inner electrons are the same as in helium, in order to obtain an idea of their size. The ionization potential of the first electron of He is 24.5 volts and of the second 54.1. Hence, we may write $78.6 = 2 \times 13.54$ ($2-\alpha$). This gives for α , the screening constant, 0.296. Using this same screening constant for lithium ion, the radius of the orbit would be $\frac{0.53}{3-0.296}$ or 0.2Å. if the orbits were circular. Hence, it would seem that the value obtained for b above is reasonable. It is also interesting to note that if we use this same screening constant for hydride ion we obtain 0.14 volts as the electron affinity of hydrogen. This is about the value to be expected from the stability of the hydride ion.

¹² Birge and Brackett, paper read before the American Physical Society, April, 1923. The relation which these authors have traced between the external and internal orbits seems to give quite accurately the field of force acting upon the electrons of the atomic kernel. It does not, however, give the force acting upon an additional electron.

tum relations in the dynamic atomic systems, it might be predicted that the total decrease in potential energy of the system would be divided equally between the increase of kinetic energy of the electrons and the energy liberated. In such a case it would be meaningless to calculate the heats of ionization in terms of the effective charges on the ions. It is of interest, however, to overlook such an a priori assumption and see how far we can go toward calculating the heat of ionization from the fields of force and the assumption that the energy is due to the change in electrostatic potential of the ions.

In the gaseous molecule of hydrogen chloride the atomic centers are separated 1.27 Å., as determined from the band spectrà¹³ of the molecule. If unit positive and negative charges separated by infinity were brought up to this distance, the decrease in potential energy, eE/d would be 11.3

volts. Experimentally, we have found 13.6 volts for the ionization of hydrogen chloride. This larger value might be accounted for by assuming an increase in the effective charge of the chloride corresponding to Curve a, Fig. 2. However, from a consideration of the heat of ionization of lithium chloride, we obtain quite a different effective charge for the chloride. The closest approach of a lithium ion and chloride ion in the solid is 2.55 Å. The band spectra for the lithium chloride are not known but, in general, the diameters of gaseous molecules are approximately 10% less than in the solid. Using 2.3 Å. as the separation of atomic centers, in order to obtain a change of potential energy of 7.3 volts, we should have to assume that the curve for the effective charge on the chloride ion corresponds roughly to b, Fig. 2.

¹³ (a) Reiche, Ann. Physik, 58, 657 (1919). (b) Urey, This Journal, 45, 1445 (1923).

In other words, the presence of a positive ion affects the whole structure of the chloride ion. It is obvious, then, that the total energy change cannot be found from the change in potential energy of the ions as a whole considered as rigid structures, but must take into account the changes of potential (and probable kinetic) energy of the electrons in each ion as well.

The approximate treatment of the electrons in a dynamic atom, as located in definite positions, may be justified on the ground that these positions represent time average or effective positions. The greatest objection, however, to the treatment of Born and his associates is the assumption of a rigid structure and thus a complete neglect of changes in energy due to the distortion of the electronic arrangement. It would seem that further attempts in this direction are not likely to be profitable.

Summary

A tabulation has been made of the heats of ionization in the gaseous state of the hydrogen and alkali chlorides, bromides and iodides.

The ionization constant of sodium chloride at its boiling point has been found to be 4×10^{-13} .

From a consideration of the fields of force about the ions and the molecular diameters it would seem that the heats of ionization cannot be calculated by any method which treats the ions as rigid structures of electrons about a positive center.

A THEORY OF CHEMICAL REACTIVITY

By F. O. RICE

RECEIVED AUGUST 3, 1923

The influence of temperature on the rate of chemical change is so marked that it is obviously a very important factor in any theory of chemical reactivity. Explanations for the high temperature coefficients of chemical reactions usually center round the empirical equation of Arrhenius¹ connecting velocity of reaction and temperature, which in the integrated form is $2.3026 \log k_1/k_2 = \frac{Q}{R} \left(\frac{1}{T_2} - \frac{1}{T_1} \right)$. Considering the hydrolysis of cane sugar by hydrochloric acid in aqueous solution, Arrhenius suggested that the cane sugar was present in two forms, active and inactive, in mass-action equi-

¹⁴ Thus, the fundamental idea of G. N. Lewis' theory of valence, that in non-polar compounds a chemical bond consists of a pair of electrons, remains essentially the same whether we consider the electrons as actually located between the atoms or rotating in orbits with that position as their effective location.

¹ Arrhenius, Z. physik. Chem., 4, 226 (1889).

librium, the equilibrium concentration of the active form being very small. In such a case as this it is evident that the concentration of the active form will vary rapidly with the temperature, for it will be proportional to the equilibrium constant of the reaction, active \longrightarrow inactive molecules, and the quantity $\mathcal Q$ in the Arrhenius equation will be the heat of the reaction, active \longrightarrow inactive molecules. The radiation theory offers a similar explanation, except that the two forms of the sugar molecules are not in mass-action equilibrium, the difference between the two forms being due to absorption by the sugar molecule of infra-red radiation, the molecule becoming active when its total energy exceeds a certain value.

It should be noted, however, that there is no a priori reason for supposing that the cane sugar exists in two forms; we might select any one of the three entities, cane sugar, water and hydrogen ion, taking part in the reaction. and by saving that it was present in two forms, we could deduce the Arrhenius equation. The justification for the particular selection would of course depend on the further development of the theory. The criticisms which were made during a recent discussion of the radiation theory,2 and the inability of the theory to explain certain results recently obtained in this Laboratory³ have led me to propose a modification of the Arrhenius theory in which the hydrogen ion is supposed to exist in two forms, active and inactive, in mass-action equilibrium. The active form is identified as the unhydrated hydrogen ion, the hydrated form and the undissociated acid having no catalytic activity; similar assumptions are made for hydroxyl-ion catalysis. Whereas on both the Arrhenius theory and the radiation theory every chemical reaction should have a unique temperature coefficient depending on the heat of activation of the substance undergoing change, it is evident that this new theory predicts that chemical reactions will fall into comparatively few classes, each having a characteristic temperature coefficient. That there is this tendency may be seen from the temperature coefficients obtained in the acid hydrolysis of substances containing the carbonyl group. A very great number of studies of this type of reaction have been made, and almost without exception the value of k_{35}/k_{25} lies between 2.2 and 2.5. The value of k_{35}/k_{25} for the acid hydrolysis of ethyl acetate,4 formyl acetic acid5 and ethyl cyano-acetate6 are all 2.4, within experimental error; on the old theories we have to assume that these compounds all have the same heat of activation or critical increment.

Perhaps the most striking deduction which may be made from this new theory is that stoichiometrically neutral water may not be neutral cata-

lytically. We consider water to be neutral when the total hydrogenand hydroxyl-ion concentrations are equal, and since the unhydrated ions are present in very minute concentrations we shall also have the concentrations of the hydrated ions equal at this point. The concentrations of the unhydrated ions will not be equal, however, and if, as I shall show later, the affinity of the hydrogen ion for water is greater than the affinity of the hydroxyl ion, a stoichiometrically neutral solution will be alkaline catalytically. It is only by making the solution acid stoichiometrically that the concentrations of the two unhydrated ions will become equal and the solution will have a minimum catalytic activity.

Theoretical Outline

Since the views herein expressed are somewhat at variance with those currently accepted I will state briefly the assumptions made in the development of the theory. It is assumed that the law of mass action first enunciated by Guldberg and Waage is correct in its classical form, namely, that the concentration of a substance is a sufficiently exact and complete mode of representing its chemical reactivity. Such statements as "One and the same substance exhibits a different degree of reactivity according to the nature of its surroundings, that is, according to the nature of the medium in which it is dissolved," are explicitly denied. It is not the massaction law but our system of stoichiometric equations that has broken down. For example, it will be shown that if we assume that only the unhydrated hydrogen ion is catalytically active we obtain a satisfactory explanation of experimental results, yet in our stoichiometric equations and in our methods of determining hydrogen-ion concentrations it is implicitly assumed that the total hydrogen ion is catalytically active. It is not surprising, therefore, that the mass-action law fails to hold.

That our stoichiometric equations do not truthfully represent what occurs may easily be seen by considering such reactions as that between the thiosulfate ion and iodine, or between silver nitrate and sodium chloride; even if the reacting species are present in concentrations as low as $0.00001\,N$ the reaction proceeds practically instantaneously, and a great many other cases may be mentioned in which there is practically instantaneous reaction, although the concentrations of the reactants may be very low. It follows, therefore, that even at concentrations as low as $0.00001\,N$ the number of molecular collisions is sufficient to permit a reaction to be practically instantaneous. If, however, we consider reactions which proceed with measurable velocity, the stoichiometric concentrations of the reactants may all be $0.1\,N$ or even higher, yet it may take over an hour for $^1/_{10}$ of the reactants to disappear. The theory explains this difficulty by postulating that in such cases the reactants are not those represented by the stoichiometric equations, but that due to combinations with the

solvent at least one of the reactants is present in very minute concentration with consequent reduction in the number of molecular collisions. On the other hand the radiation theory explains the difficulty by assuming that only a small fraction of the collisions are effective. It may be pointed out here that the rule that the temperature coefficient of a strongly catalyzed reaction should be less than that of a feebly catalyzed one depends upon the possibility of changing a large proportion of inactive to active molecules, in other words of bringing the concentration of the active molecules to ordinary stoichiometric concentrations. In this case the reaction should be practically instantaneous, so that we must conclude on the basis of both the Arrhenius theory and the radiation theory that the temperature coefficient is independent of the velocity of the reaction in those cases in which the velocity is measurable.

I will now consider a particular class of reactions, namely, the case where we have hydrogen-ion catalysis by a strong acid in which the solvent does not enter directly into the reaction. Assuming that the strong acid is practically entirely dissociated, the total hydrogen ion will be present as hydrated hydrogen ion and a minute quantity as unhydrated hydrogen ion; in this case the unhydrated hydrogen ion is supposed to be the only active molecule, so that all these reactions should have the same temperature coefficient. This would hold for any solution in which the hydrogen ion is combined only with water, for the variation with temperature of the concentration of the unhydrated ion depends on its heat of combination. Therefore the temperature coefficient should not be affected by the presence of non-electrolytes or neutral salts, since the affinity of hydrogen ion for water is so great9 that it is unlikely that there will be any extensive combination between the hydrogen ion and these substances. For this conclusion regarding the temperature coefficient to be true, it is necessary to assume that the mass-action law holds and that viscosity effects are negligible. A study of the reaction between acetone and iodine showed that the value of k_{35}/k_{25} was 3.0814 \pm 0.20% whenever the catalyst was a strong acid, although in some cases neutral salts in concentrations from 1 to 4 N, and non-electrolytes in concentrations from 5 to 30% were present. This result is very striking because we were unable to alter the tem-

⁷ W. C. M. Lewis [Scientia, 25, 450 (1919)]. "The fact, that many reactions occur with a finite and measurable velocity, shows us that all the molecules are not in the same chemical state. If they were, the speed of the reaction would either be zero or infinite." Taylor [J. Phys. Chem., 27, 322 (1923)] has put forward a theory of negative catalysis based on these considerations. "The theory emphasizes anew the fact that the concentration of a substance is not the active mass of the substance, but a very much greater quantity."

⁸ Lamble and Lewis, J. Chem. Soc., (a) 105, 2330 (1914); (b) 107, 233 (1915).

⁹ Born, Ber. physik. Ges., 21, 679 (1919). Fajans, ibid., 21, 649 (1919). A résumé of this work is given by Taylor, Newer Aspects of Ionization Problems, Trans. Am. Electrochem. Soc., 43, preprint (1923).

perature coefficient in the slightest degree when the catalyst was a strong acid. When, however, weaker acids were used as catalysts, that is, when the state of combination of the hydrogen ion was affected, the temperature coefficient fell. It will be shown in a later section that with weaker acids the concentration of the hydrated hydrogen ion diminishes with rise in temperature thus giving a lower temperature coefficient.

In reactions which are hydrolytic in character I assume that a compound is formed between the substance A undergoing hydrolysis and the water; that in general only a small fraction of the substance A is present as hydrate, and that the hydrolysis takes place by collision of the unhydrated hydrogen ion with the hydrate. It will be seen that the hydrate of the substance A now becomes an active molecule and the temperature coefficient of the reaction will depend on whether the heat of hydration of A is positive or negative. I have thus covered practically all cases of hydrogen-ion catalysis, and the treatment of hydroxyl-ion catalysis is exactly similar.

We can conclude, therefore, that chemical reactions will fall into comparatively few classes, each class having a characteristic temperature coefficient. The temperature coefficient of a reaction is fixed by the number and nature of the active molecules, and all types of reaction which have the same active molecules will have exactly the same temperature coefficient. The variation with temperature of the concentration of the active molecule will depend on its heat of combination with the solvent or other constituents of the solution with which it combines. According as its heat of formation is positive or negative the concentration of the active molecule will decrease or increase with rise of temperature; an active molecule, therefore, on this theory has no particular virtue because of its internal energy content. If we measure the velocity of a reaction at two temperatures, and substitute the values in the Arrhenius formula we shall obtain directly the heat of combination of the active molecule if its formation is represented by an equation such as $B + C \Longrightarrow A$ where A is the active molecule. In other cases the calculated value of Q will usually be a simple multiple or sub-multiple of the heat of reaction, and in cases where there is more than one active molecule the value of Q will be the algebraic sum of these quantities. Since Q is a heat of reaction, it will vary slightly with the temperature, and this variation could be calculated if the specific heats of the reactants and resultants were known as functions of the temperature. In those reactions which have the same active molecules, the value of Q and its variation with the temperature will be the same.

In concluding this section I wish to refer briefly to unimolecular chemical changes. Perrin² in support of the radiation theory, has pointed out that in unimolecular chemical reactions the velocity is independent of the number of collisions per second and can, therefore, be due only to some out-

side agency, presumably radiation. This argument would be much more convincing if we had an example of a chemical reaction which proceeded with measurable speed and was really unimolecular; all the examples quoted¹0 by Perrin are really pseudo-unimolecular, in which catalysts or traces of water vapor are required for the reaction to proceed. There does not appear to be a single case of a chemical reaction which proceeds with measurable speed and which we are reasonably certain is a true unimolecular reaction. It may be pointed out here that the decomposition of nitrogen pentoxide¹¹ which appeared to be a case of a unimolecular change has now been shown¹² to be at least bimolecular, small traces of the decomposition products being necessary to secure a constant specific rate of decomposition.

Hydrogen-Ion Catalysis by Strong Acids

That there exists in aqueous solution more than one type of hydrogen ion has long been recognized. In a recent paper¹³ Kendall states "the hypothesis of the catalytic activity of the undissociated molecule which purports to explain why the speed of reactions such as ester catalysis is not exactly proportional to hydrogen-ion concentration may be discarded in favor of a view which recognizes several types of hydrogen ion (e. g., H+, [H(H₂O)]+, [H(R.COOR)]+) each possessing a different catalytic activity." The view which I have adopted in this paper is that only the free hydrogen ions are catalytically active, and that these correspond with the active molecules of Arrhenius. When the hydrogen ion is in combination, either as the undissociated molecule or as hydrated hydrogen ion, the resulting compound has no catalytic activity, or a relatively small catalytic activity; these compounds would correspond to the inactive molecules of Arrhenius.

Lapworth¹⁴ and his co-workers first put forward the view that the unhydrated hydrogen ion was the catalytically active particle and that the hydrated hydrogen ion had little or no catalytic activity. They examined a number of widely different cases of hydrogen-ion catalysis in alcohol and showed that all occurred enormously faster in alcohol than in water, and further that the addition of minute quantities of water caused a marked retardation of the velocity. He states, "The proposition that free hydrogen ions are responsible for the catalytic activity of acids leads to the conclusion that they must be relatively few in number in aqueous solution. On the other hand the original conception of hydrogen ions was applied

to explain the conductivity of acids in aqueous solution, so that the terms are not synonymous. In the latter case, they must be complex ions, probably of the form (H₂O.H)+." Dawson, 15 from experiments on the reaction CH₃COCH₃ + I₂ in water and water-alcohol mixtures, also supported this view. He showed that in alcohol solutions containing small quantities of water the reaction velocity was proportional to the concentration of the acetone, but was not proportional to the concentration of the acid catalyst. In such solutions the velocity increased much more rapidly than the concentration of acid catalyst. He concludes, "By comparison of the observations in aqueous with those in alcoholic solution we are led to the conclusion that the ionic component responsible for the catalytic effect is the free hydrogen ion, and that the effect of the hydrated ion is relatively unimportant. The concentration of the free hydrogen ions is very small in comparison with the total ion concentration, and in order to produce the observed effects it must be assumed that their specific catalytic activity is Since the ratio of the free hydrogen ion to the total hydrogenion concentration is so small the electrical conductivity of the solution is mainly determined by the complex ions, and the catalytically active ions are of little consequence in so far as the conductivity of the acid solution is concerned."

I will first apply this theory to the case of hydrochloric acid in aqueous solution, since the reasoning applies equally well to all strong acids. Writing the equilibria involved, 16 we have

$$HCl + nH_2O \Longrightarrow HCl.nH_2O$$
 (1)

$$HCl.nH2O \Longrightarrow (H.aH2O) + + (Cl.bH2O) -$$
 (2)

$$(H.aH2O) + \Longrightarrow H^{+} + aH2O$$
 (3)

where n=a+b. The problem is to find out how the unhydrated hydrogen ion in Equation 3 varies with the temperature, for this variation determines the temperature coefficient of the reaction. In the first place I will assume that at temperatures of 0° to 35° Reactions 1 and 2 go practically to completion, that is, that in aqueous $0.1\ N$ solution hydrochloric acid is almost entirely dissociated. The concentration of the hydrated hydrogen ion will not vary, therefore, very much with the temperature, and for small temperature intervals we may write it as a constant without making much error. Considering Reaction 3 at 25° and 35° we have the ratio

of the equilibrium constants $K_{25}/K_{25} = \frac{(\mathrm{H}^+)_{35} \times (\mathrm{H}_2\mathrm{O})_{25}^a}{(\mathrm{H}^+)_{25} \times (\mathrm{H}_2\mathrm{O})_{25}^a}$ and since the heat

of hydration¹⁷ per g. of hydrogen ion is 262,000 cal., this ratio is of the order of 10.¹⁴ Increase in temperature, therefore, strongly favors the formation of the unhydrated hydrogen ion, but unfortunately since we do not know

¹⁵ Dawson, J. Chem. Soc., 99, 1 (1911). Dawson and Powis, ibid., 105, 1093 (1914).

¹⁷ Fajans, Ber. phys. Ges., 21, 709 (1919).

the concentration of the simple water molecules present in the solution nor the number of water molecules in combination with the hydrated hydrogen ion we cannot calculate the change in concentration of the unhydrated hydrogen ion with temperature, which would give us the temperature coefficient of a reaction catalyzed by this acid. We can state, however, that a reaction will have the same temperature coefficient provided it is catalyzed by a strong acid, for the temperature coefficient is fixed by Reaction 3 and this is independent of the kind of acid used provided it is almost entirely ionized. A search of the literature showed that very few such measurements have been made, the great bulk of the studies having been made on reactions which are hydrolytic in character. Harned and Seltz¹⁸ have measured the temperature coefficient of the change, acetyl-chloro-amino-benzene -> p-chloro-acetanilide, catalyzed by hydrochloric acid. Their results give the mean value of k_{35}/k_{25} as 3.14, which is in fairly good agreement with the theoretical value, 3.0814. Slator¹⁹ has studied the temperature coefficients of the reactions between a great number of alkyl halides and sodium thiosulfate. The temperature coefficients in all cases had the value 3 within experimental error, which suggests that these reactions are really cases of hydrogen-ion catalysis. A more rigid test of the theory is at present being conducted in this Laboratory, by measuring the temperature coefficients of the reactions of iodine with various ketones and aldehydes. Mr. C. F. Fryling, using the improved technique³ already described, has found that although the velocities vary widely, all of the temperature coefficients k_{35}/k_{25} have the value $3.081 \pm 0.16\%$, without a single exception. A description of this research will be communicated shortly. Work is also in progress to extend these measurements to other reactions.

Hydrogen-Ion Catalysis by Moderately Strong and Weak Acids

If we write Equations 1 and 2 of the previous section as one equation and generalize by writing X for the acid radical we have: $HX + nH_2O \rightleftharpoons (H.aH_2O)^+ + (X.bH_2O)^-$. In general, this reaction will be exothermic, so that a rise in temperature will send the reaction towards the left. In the case of strong acids where the concentration of the undissociated acid (HX) is very small, an increase of temperature will not affect the concentration of the hydrogen ion $(H.aH_2O)^+$ appreciably, because only a slight movement of the equilibrium towards the left is necessary to alter markedly the value of the equilibrium constant. In the case of weaker acids where the undissociated molecule is present in appreciable amounts, increase in temperature should cause an appreciable diminution in the concentration of the hydrated hydrogen ion $(H.aH_2O)^+$, and this diminution should be

¹⁸ Harned and Seltz, This Journal, 44, 1475 (1922).

¹⁹ Slator, J. Chem. Soc., 85, 1286 (1904).

greater the weaker the acid. The presence of neutral salts might be expected to increase this effect, since their effect is to make the acid appear weaker. It is evident, therefore, that in the case of weaker acids, since the concentration of the hydrated hydrogen ion diminishes with rise in temperature, the increase in concentration with temperature of the unhydrated hydrogen ion is partly neutralized; this means that weaker acids should have lower temperature coefficients than strong acids, a result which is in accord with experiment. The values of Q for the reaction between acetone and iodine when catalyzed by 0.1 N hydrochloric acid and 0.1 N sulfuric acid are 20,540 and 19,070, respectively, so that the ratio $Q(HCI)/Q(H_2SO_4) = 1.077$; this same ratio should be found for any other reaction whatsoever, provided that it is carried on in moderately dilute aqueous solution.

Hydrogen-Ion Catalysis. Hydrolysis

Consider the hydrolysis of ethyl acetate by hydrochloric acid. Writing the equilibrium for ethyl acetate and water we have: CH3COOC2H5 $+ nH_2O \rightleftharpoons CH_3COOC_2H_5, nH_2O$. I will assume that only a small fraction of the ethyl acetate is present as hydrate and that the hydrolysis takes place by collision of the unhydrated hydrogen ion with the ethyl acetate hydrate. If the bulk of the ethyl acetate were present as hydrate or if the heat of hydration of the ethyl acetate were zero we should have a case similar to that treated in the section previous to the last, and the temperature coefficient, k_{35}/k_{25} , would be 3.08. Since, however, we have assumed that the ethyl acetate hydrate is present only in small concentration compared with the total ethyl acetate, the temperature coefficient will be lowered if the hydrate is formed with evolution of heat, and raised if the hydrate is formed with absorption of heat. The heat of dilution of aqueous methyl acetate is positive, which indicates that the hydrate is formed with evolution of heat and hence its concentration will diminish with rise in temperature. The heat of hydration of all esters containing the carbonyl group will probably have about the same value, so that in all cases of hydrolysis of such esters by strong acids the temperature coefficient should be about the same and be less than 3.08. Inspection of the literature shows that almost without exception the values of k_{35}/k_{25} for such reactions lie between 2.2 and 2.5. If instead of ethyl acetate in the above equation we substitute another substance capable of hydrolysis but having a negative heat of hydration, the concentration of the hydrate will increase with rise in temperature and the temperature coefficient, k_{35}/k_{25} , will be greater than 3.08. The value of k_{35}/k_{25} for the hydrolysis of cane sugar^{8b} is slightly over 4, which indicates that the combination of the cane sugar with the water molecule which takes part in the hydrolysis, is an endothermic reaction. It does not seem possible, however, to test this experimentally at present. The results given in the literature for the acid hydrolysis of amides are so contradictory that it is not possible to test the theory in this case either. From the results of Crocker²⁰ and of Kilpi,²¹ $k_{35}/k_{25} = 3.4$. Peskoff and Meyer²² studied the hydrolysis of six amides; the values of k_{35}/k_{25} which they obtained for the different amides were erratic and varied between 2.52 and 3.29.

Hydroxyl-Ion Catalysis

If we write the equilibria involved when a base (B) is dissolved in water we have,

$$BOH + nH_2O \Longrightarrow BOH.nH_2O$$
 (1a)

$$BOH.nH2O \Longrightarrow (B.aH2O) + + (OH.bH2O) -$$
 (2a)

$$(OH.bH_2O) \rightleftharpoons OH^- + b.H_2O$$
, where $n = a + b$. (3a)

I assume here that only the free hydroxyl ion has any catalytic activity, and that when the hydroxyl ion is combined either with water or in the base, the resulting compound has no catalytic activity. The reasoning to be followed then becomes exactly the same as in hydrogen-ion catalysis; all reactions catalyzed by a strong base where the hydroxyl ion is the only active molecule, will have the same temperature coefficient, reactions catalyzed by weaker bases will have a lower temperature coefficient, and reactions involving the hydrolysis of compounds containing the carbonyl group will have a still lower temperature coefficient. As in the case of hydrogen-ion catalysis hardly any data are available for testing this except for the case of hydrolytic reactions. The value of k_{35}/k_{25} for the reaction between acetone and iodine has been measured in this Laboratory by Mr. M. Bergstein, and found to be 2.52 when the reaction was catalyzed by an alkaline buffer solution. Reicher²³ measured the rate of hydrolysis of ethyl acetate by sodium hydroxide at 24.22° and 35.14°; the value of O calculated from these two results is 10,950, whence $k_{35}/k_{25} = 1.82$.

Wilsdon and Sidgwick, 24 and also Boeseken and Verkade 25 have studied the rate of hydration of acid anhydrides. These reactions are not catalyzed by hydrogen ions but are very strongly catalyzed by hydroxyl ions. It is suggested, therefore, that they are really cases of alkaline hydrolysis similar to the case of nitrocamphor investigated by Lowry, 26 the hydroxyl ion being derived from the glass or from organic alkaline impurities in the acetic anhydride. Wilsdon studied the rate of hydration of acetic, propionic and camphoric anhydrides at 18° and 25°. The average value of k_{25} /

²⁸ Lowry, J. Chem. Soc., 93, 107 (1908).

 k_{18} was 1.57, average deviation 3.6%, maximum deviation 5.7%. These deviations are probably within experimental error, yet the rate of hydration of acetic anhydride is almost ten times as great as that of camphoric anhydride. Using this average value, Q=11,100 and k_{35}/k_{25} (calculated) is equal to 1.84 as compared with 1.82 for the alkaline hydrolysis of ethyl acetate. Boeseken and Verkade studied the rate of hydration of propionic, butyric and *iso*butyric anhydrides at 0° and 25° , and obtained similar results.

The temperature coefficient for the hydrolysis of amides by alkalies should be somewhat greater than 2.52 which was obtained for the reaction between acetone and iodine when catalyzed by the hydroxyl ion. Peskoff and Meyer have obtained an average value for k_{35}/k_{25} equal to 2.65 for the alkaline hydrolysis of six amides.

Point of Minimum Catalytic Activity

An aqueous solution is ordinarily considered neutral when the total hydrogen-ion concentration is equal to the total hydroxyl-ion concentration, in which case the hydrated forms of the two ions will be present in practically equal concentrations. It will be readily seen that in such a solution the concentrations of the unhydrated forms of the two ions may be very far from being equal, so that a stoichiometrically neutral solution may not be neutral catalytically. Indeed, from the work of Fajans and of Born⁹ it is clear that the smaller the ion, the greater is its affinity for water: therefore, we should expect the hydrogen ion to have a much greater affinity for water than the hydroxyl ion, and consequently in a stoichiometrically neutral solution where the hydrated forms of the hydrogen ion and hydroxyl ion are present in equal concentrations, the unhydrated hydroxyl ion will be present in much greater concentration than the unhydrated hydrogen ion. By acidifying the solution we should reach a point where the concentrations of the two unhydrated ions are equal, and this would be the point of minimum catalytic activity, assuming that the catalytic activities of the two ions are about equal. The phenomenon was first noticed in this Laboratory in some preliminary work concerned with the measurement of reaction velocity. It was found that the saturated borax-boric acid buffer which was supposed to be neutral, catalyzed the reaction at about the same rate as 0.001 N hydrochloric acid. The acetone was finally converted into iodoform which indicated that the catalyst was hydroxyl ion. The matter was not investigated further at that time, the difficulty being overcome by rapid titration of the iodine. Since then the catalytic activity of buffer solutions on the reaction has been studied in this Laboratory by Mr. M. Bergstein, and the results will be communicated shortly. In all the cases investigated a point of minimum catalytic activity was found to lie about PH 5. This abnormal behavior

TOTE THE LINE

of aqueous solutions near the neutral point has been commented on in two papers. Karlsson²⁷ investigated the effect of hydrogen-ion concentration on the stability of methyl acetate and ethyl acetate. The experiments were made at 75° and 85° in presence of a buffer solution of known hydrogen-ion concentration and the esters showed greatest stability at Sörensen (Рн) values between 4.7 and 5.1. Dawson and Powis²⁸ investigated the autocatalytic reaction, $CH_3COCH_3 + I_2 = CH_3COCH_2I + HI$. "If x represents the concentration of hydrogen iodide which has been set free after time t in an originally 'neutral' aqueous solution containing c molecules of acetone per liter and a relatively small quantity of iodine, then the velocity at this moment should be given by dx/dt = kcx, where k denotes the velocity in a solution containing one molecule of acetone per liter and one molecule of halogen acid per liter." The integrated form of the equation is $\ln x$ = kct + a constant, and by extrapolation of the straight line obtained by plotting $\ln x$ as a function of t, the initial speed of the reaction was found. This corresponded to a hydrogen-ion concentration of PH 4.7.

It would appear, therefore, that in order to attain a minimum rate of reaction in aqueous solution, or maximum stability of compounds which are decomposed catalytically, it is necessary to keep the stoichiometric hydrogen-ion concentration near 10^{-5} . The hypothesis that the unhydrated hydrogen and hydroxyl ions are the catalytically active particles provides a satisfactory explanation of these abnormalities. Stoichiometrically neutral water is distinctly alkaline catalytically and it is only when the stoichiometric concentration of the hydrogen ion approaches $P_{\rm H}$ 5 that the solution has minimum catalytic activity. The explanation of Karlsson that the hydrogen and hydroxyl ions do not have the same activity is probably only partly an explanation of the phenomenon, because on his explanation we have to assume that the hydroxyl ion is several hundred times as active catalytically as the hydrogen ion and that this same ratio holds for many different reactions.

Summary

- 1. An explanation for the high temperature coefficient of chemical reactions is offered in which it is assumed that the mass-action law in its classical form is true, and that its apparent failure is due to using stoichiometric equations which do not represent even approximately the reactions taking place in the solution.
- 2. When the ordinary stoichiometric equations are replaced by equations representing more nearly what occurs, it has been shown that certain molecules are connected with an equilibrium constant in such a way that their concentrations vary rapidly with the temperature. These are re-

²⁷ Karlsson, Z. anorg. Chem., 119, 69 (1921).

²⁸ Dawson and Powis, J. Chem. Soc., 101, 1503 (1912).

ferred to as active molecules, and it is due to these that "slow" reactions have a high temperature coefficient.

- 3. The theory predicts that chemical reactions will fall into comparatively few classes, each class having a characteristic temperature coefficient.
- 4. In this theory the assumption is made that the unhydrated hydrogen and hydroxyl ions are the catalytically active particles, and this leads to the conclusion that stoichiometrically neutral water is distinctly alkaline catalytically, and it is not until the hydrogen-ion concentration has a value about $P\pi$ 5 that the concentrations of the unhydrated ions become equal, and the catalytic activity is at a minimum.

INVESTIGATIONS ON THE PLATINUM METALS. IV.1 THE DETERMINATION OF IRIDIUM IN PLATINUM ALLOYS BY THE METHOD OF FUSION WITH LEAD2

By Raleigh Gilchrist³ Received August 9, 1923

Introduction

A critical study of the Deville and Stas⁴ method for the determination of iridium in platinum alloys was undertaken at the Bureau of Standards as the first of a series of investigations into the analytical methods for the metals of the platinum group.

The Deville and Stas Method

Deville⁵ found that when platinum alloyed with iridium, rhodium, palladium, iron and copper is dissolved in lead at a high temperature, the lead forms alloys with all of the platinum, rhodium, palladium and copper, and with a very small proportion of the iron. The iridium, ruthenium and iron form a separate alloy containing no lead. Boiling dil. nitric acid removes the bulk of the lead together with the palladium and copper and

a small proportion of the platinum and rhodium. Digestion of the residue with warm, dil. aqua regia leaves insoluble only the alloy of iridium, ruthenium and iron.

The Deville and Stas procedure has been used at the Bureau of Standards for six years but with a few modifications in apparatus and technique.

Details of the Analysis Made the Subject of Investigation

In order to arrive at the optimum conditions for the determination of iridium in platinum alloys a study was made of the following details: magnitude of the error caused by the incomplete separation of iridium; variation of the concentration of nitric acid and of aqua regia used; variation of the proportion of lead to alloy and of the time and temperature of the lead fusion; effect of ruthenium, rhodium, palladium, gold and iron and the effect of ignition in air and of reduction in hydrogen on the weight of crystalline iridium.

Preparation of Alloys for Analysis

The alloys were specially prepared for this investigation from metals of the highest purity. The platinum had been prepared for use in thermocouples and its spectrum showed only a trace of calcium. The iridium had been fused with lead and its spectrum showed the presence of traces of platinum, rhodium, ruthenium, lead and iron that were so small, however, that they could have no appreciable effect on the composition of the alloys. The palladium was free from base metals, while the rhodium sponge may have contained a trace of lead, but both were free from the other platinum metals. The spectrum of the gold indicated a trace of silver and copper.

The alloys were melted in an Ajax-Northrup high frequency induction furnace^{1c} using pure lime or purified thoria as the refractory. The platinum used was either in the form of an ingot or of wire compressed into a pellet in a steel mold. The finely crystalline iridium was wrapped in a small cylindrical shell of pure platinum in order to avoid loss. The molten alloys were stirred vigorously by the effect of the induced electric current. With the exception of the iron-iridium alloy which was cast in graphite the melts were allowed to freeze in the crucibles.

From experience gained in the melting of preliminary samples of pure platinum and of platinum-iridium alloys, the small loss in weight on melting was considered to be a loss of iridium. The percentage of iridium put into the mixture of metals represented, therefore, the maximum iridium percentage of the alloy, while the minimum average percentage was calculated by deducting the percentage loss in weight which occurred in melting.

Danger of Non-Uniform Sampling

Early analyses indicated the necessity of careful sampling because of the non-homogeneity of some of the alloys. The first alloy of the final series (containing 20% of iridium) was drawn to wire of 0.60mm. diameter and cut into fragments varying from 1 to 2 mm. in length. The variation in analytical results led to the belief that this method of sampling was inadequate. The subsequent alloys made were drawn to 0.36 mm. and cut into lengths of 1 mm. The cut wire in every case was cleaned from superficial iron by hot coned. hydrochloric acid, washed with distilled water and ignited to dull redness in a porcelain crucible. Samples for analysis were taken from different parts of the mass.

Results of Analyses

Incomplete Determination of Iridium.—Early in the experimental work iridium was detected qualitatively in the aqua regia solution. Although the amount in this case was small, it was evident that some iridium was being lost. In order to determine the magnitude of this error, iridium was recovered from the aqua regia solutions in the analysis of a number of the alloys. The total aqua regia solution was evaporated to dryness, the nitric acid eliminated by hydrochloric acid, ammonium chloride added, the mass of salt dried, reduced in hydrogen and the resulting metal fused with lead as in the regular procedure for an alloy. Calculated in percentage on the basis of the weight of the alloy samples taken, of the 33 recoveries made 20 were less than 0.05%, 7 were between 0.05 and 0.10%, 4 were between 0.10 and 0.15%, and 2 were between 0.15 and 0.30%.

There was no uniformity in the quantity of iridium which escaped the first determination, considering either individual experiments or the averages from different alloys, although these alloys differed considerably in iridium content. It seems unlikely that more than a very small quantity could have been involved in a mechanical loss, since the utmost precautions were taken to effect a quantitative transfer and a double filter was used, both layers of which were of paper of close texture. There was probably some solution of the iridium by the aqua regia in all cases, but the reason why the amount dissolved should vary between wide limits is not apparent. In reporting the analyses in which this second determination of iridium was made, the total iridium is the value considered in the discussion of the results. Such recoveries were made except in the analyses discussed under the headings "Variation of the Concentration of Nitric Acid," "Effect of Palladium and Gold" and the "Effect of Iron."

Experiments on the Variation of the Concentration of Nitric Acid Used to Disintegrate the Lead Button.—Eight analyses were made on 4g. samples of an alloy containing a maximum of 4.85% of iridium and a minimum of 4.82%. Each of the three analyses in which the nitric acid concentration was 1:8 gave the value 4.83%. Three determinations with 1:4 nitric acid gave 4.83, 4.85 and 4.83%. Two determinations with 1:2 nitric acid gave 4.79 and 4.80%.

Although the variation of the concentration of nitric acid had little effect on the iridium determination, it was found that the 1:2 nitric acid produced a residue which was finely divided and difficult to filter, thereby offsetting any advantage gained over the 1:4 nitric acid by a saving of time.

In this and subsequent experiments the temperature of the solutions was maintained at about 85° (steam-bath) and double filters were always used.

Experiments on the Variation of the Concentration of Aqua Regia Used to Separate the Iridium from the Lead-Platinum Alloy.—Seven analyses were made on 2g. samples of an alloy containing a maximum of 20.20% of iridium and a minimum of 20.11%. The average of three experiments, with 1:10 aqua regia was 19.99%; that of two experiments with 1:5 aqua regia, was 20.09%; and that of two experiments using 1:2.5 aqua regia was 20.06%. The seven individual results varied from 19.98 to 20.12%.

Such variations as appear in the results are probably to be ascribed to somewhat inadequate sampling rather than to the variation of the concentration of the aqua regia. Consistent results were obtained in the analysis of a 10% iridium alloy and of a 5% iridium alloy containing gold and palladium, in which analyses the concentration of aqua regia was 1:2.5.

Experiments on the Variation of the Duration of the Lead Fusion.— Nine analyses were made on 2g. samples of an alloy containing a maximum of 20.20% of iridium and a minimum of 20.11%. The average of three experiments with a 4-hour fusion period at 1000° was 19.99%, of two with a 2-hour period was 20.05%, of two with a 1-hour period was 20.11%, and of two with a 1/2-hour period was 20.05%. The nine individual results varied from 19.98 to 20.12%.

The results show that the time of fusion with the temperature at 1000° may vary over a wide range without affecting the determination.

Experiments on the Variation of the Proportion of Lead to Alloy.—Seven analyses were made on 2g. samples of an alloy containing a maximum of 20.20% of iridium and a minimum of 20.11%. The average of two experiments, with 10 g. of lead to 1 g. of alloy, was 20.05%, of three, with 20 parts of lead, was 19.99% and of two, with 40 parts of lead, was 20.02%. The seven individual results varied from 19.97 to 20.09%. The proportion of lead can, therefore, be varied over a wide range without appreciably affecting the determination.

Experiments on the Variation of the Temperature of the Lead Fusion.— Analyses were made of an alloy containing a maximum of 10.26% of iridium and a minimum of 10.22%. Experiments in which 10 parts of lead to 1 part of alloy at 600° were used resulted unsatisfactorily. It was not possible to effect complete fusion. Two analyses on 1.3g. samples with a lead fusion at 800° for 1/2 hour gave 10.26 and 10.34%. Two analyses on 1.3g. samples at 800° for 4 hours gave 10.18 and 10.13%. Three

analyses on 4g. samples at 1000° for 1/2 hour each gave 10.22%. Three analyses on 4g. samples at 1000° for 4 hours gave 10.18, 10.18, and 10.12%. The results show that the temperature of the lead fusion may vary between 800° and 1000° without seriously affecting the determination. However it appears that a short fusion at 800° is not sufficient.

Experiments to Determine the Effect of Ruthenium.—Three analyses were made of an alloy containing a maximum of 9.96% of iridium and 0.51% of ruthenium and a minimum of 10.35% of iridium plus ruthenium. One experiment on a 4g. sample gave 10.44% and two experiments on 3.5g. samples gave 10.39 and 10.41%. The results confirmed the observation of Deville and Stas⁶ that ruthenium separates quantitatively with the iridium.

Experiments to Determine the Effect of Rhodium.—Five analyses were made of an alloy containing a maximum of 5.06% of iridium and a minimum of 5.01% and in addition 5.04% of rhodium. Three analyses on 4g. samples gave 5.14, 5.15, and 5.18%. Two analyses on 3.4g. samples gave 5.13 and 5.17%. The results of the two series of analyses, although concordant, are higher than the maximum percentage of iridium in the alloy. The iridium from two experiments was examined chemically for rhodium, but in both cases a quantity of rhodium not greater than 0.01% of the weight of the alloy sample taken for analysis was extracted. Iridium from a third experiment was examined by spectrographic analysis but the quantity of rhodium detected was very small. It was, therefore, concluded that the actual experimental values for iridium represented the true composition of the portion of the ingot which was prepared for analysis. Deville and Stas⁵ state that rhodium does not interfere in the determination of iridium.

Experiments to Determine the Effect of Palladium and Gold.—Six analyses were made on 4g. samples of an alloy containing a maximum of 5.35% of iridium and a minimum of 5.31% and in addition 3.07% of palladium and 2.32% of gold. Three experiments, with 1:8 nitric acid, gave 5.25, 5.29, and 5.30%. Three experiments, with 1:4 nitric acid, gave 5.29, 5.28, and 5.31%. The results show that palladium and gold have no effect upon the determination of iridium.

Experiments to Determine the Effect of Iron.—Five analyses were made on 4g. samples of an alloy containing a maximum of 4.75% of iridium and in addition 0.31% of iron. The results ranged from 5.03 to 5.12% with an average of 5.07%. The iron in the combined nitric acid and aqua regia solutions from three of these analyses was determined colorimetrically and found to be 0.02, 0.01, and 0.005% of the sample. One of the remaining solutions showed a trace of iron and the other none. Colorimetric analysis of iron in a separate sample of the alloy gave 0.31% of iron.

⁶ Ref. 4, pp. 162, 191.

A procedure for the separation of iron from iridium, suggested by W. H. Swanger of this Laboratory, was tested. It consisted of a fusion of the iridium with zinc, removal of the excess of zinc with hydrochloric acid, and fusion of the zinc-iridium alloy with potassium pyrosulfate. The insoluble residue from the digestion of the pyrosulfate fusion with dil. sulfuric acid should contain all of the iridium free from iron but contaminated with silica. After the removal of silica in the usual manner four experiments gave 4.65, 4.65, 4.71 and 4.72%.

To determine whether this procedure could be conducted without loss of iridium, experiments were made with samples of iridium containing no iron. The samples weighed 0.1940 g., 0.1945 g. and 0.1938 g. and the recoveries were 0.1951 g., 0.1933 g. and 0.1937 g., respectively.

The results of the experiments confirm the observation of Deville and Stas⁷ regarding the behavior of iron and show in this case that even a greater proportion of the iron separated with the iridium. In the analysis of some contact points containing approximately 5% of iridium and 0.16% of iron, it was also found that nearly all of the iron was weighed as iridium.

Analysis of an Alloy Containing a Small Amount of Iridium.—Three analyses were made of an alloy calculated to contain 0.084% of iridium. The samples weighed 5 g. and the results were 0.070, 0.068, and 0.066%, with an average of 0.068%. The values are seen to be slightly low. It was in the analysis of this alloy, among the first made in this investigation, that iridium was observed to be present in the aqua regia solution.

Miscellaneous Experiments.—A correction of 0.0005 g., the quantity of insoluble material introduced into the iridium during the analysis from the reagents and apparatus used, was applied to the weight of the iridium in all of the analyses reported in this paper.

It was found experimentally that in the time required for the ignition of the iridium in air in the regular analysis, namely, about one hour, there would be no significant loss in weight.

It was found experimentally that the practice of reducing and cooling the iridium in hydrogen introduced no error into the weight of the iridium.

Spectrographic examination of samples of iridium obtained from analysis showed that platinum and lead were either absent or their presence doubtful. No zinc was found in the iridium which had been fused with zinc and subsequently with potassium pyrosulfate.

Proposed Modified Procedure

The following modification of the Deville and Stas method is recommended.

1. Lead Fusion.—Fuse the carefully sampled platinum alloy with 10 times its weight of granular test lead for a period of one hour at a tem-

⁷ Ref. 4, p. 177.

perature of about 1000°. A covered crucible, whose outside dimensions are 4 cm. in diameter and 7 cm. in height, machined from Acheson graphite, is suitable for fusions made with 20 to 40 g. of lead. The inside of the crucible should possess a slight taper to facilitate the removal of the cooled ingot. Do not pour the fusion from the crucible, but allow it to solidify, since the iridium has largely settled to the bottom of the crucible. The crucible is best heated with an electric furnace.

- 2. Disintegration with Nitric Acid.—Brush the cooled lead ingot free from carbon with a camel's hair brush, and place it in a beaker. Add nitric acid of the concentration one volume of acid (d., 1.42) to 4 volumes of water, using 1 cc. of acid per g. of lead. Place the beaker on the steambath or on a hot-plate which maintains the temperature of the solution at about 85°. Disintegration of the lead ingot is usually complete in about two hours, and leaves a rather voluminous, gravish-black mass. Dilute the solution to twice its volume and decant the liquid through a double filter, consisting of a 9cm. paper of fine texture8 on which is superimposed a 7cm, paper of looser texture. Wash the residue quite thoroughly with hot water and pass the washings through the filters. The residue is not transferred to the filters at this point. The lead nitrate solutions and washings are best caught in an Erlenmeyer flask to make easier the detection of the presence of any residue which has passed through the filters. This is done by whirling the liquid in the flask. Any particles of the residue collect at the center of the bottom of the flask. Return the filters to the beaker without ignition.
- 3. Solution of the Lead-Platinum Alloy by Aqua Regia.—Add in order 15 cc. of water, 5 cc. of hydrochloric acid (d., 1.18) and 0.8 cc. of nitric acid (d., 1.42) for each gram of the platinum-alloy sample taken. Heat the solution in the beaker on the steam-bath or on a hot-plate which maintains the temperature at about 85°. The lead-platinum alloy is usually completely dissolved within one and a half hours. Dilute the solution with twice its volume of water and filter through a double filter, similar to the one used for the lead nitrate solution. The iridium, insoluble in the aqua regia, is in the form of fine crystals, possessing a bright metallic luster and having a high density. Pass the clear solution through the filter first and then transfer the thoroughly macerated paper. It is very important to examine the beaker to see that no iridium remains. To do this the interior of the beaker is wiped with a piece of filter paper to collect any metal adhering to the sides. Then by whirling a small quantity of water in the beaker any iridium remaining gravitates toward one place whence it can be removed with a piece of paper. Wash the filters and iridium thoroughly, first with hot water, then with hot dil. hydrochloric

⁸ Such as S. and S. No. 589 blue ribbon and No. 589 black ribbon papers, respectively.

acid (1:100), and lastly with hot water. The chloroplatinic acid filtrate and washings should be examined for iridium, which may have passed through the filters, in the manner described under the nitric acid treatment. The last washings should be tested for the absence of lead.

4. Ignition and Reduction of the Iridium.—Place the washed filters and iridium in a porcelain crucible and dry, before igniting in air. After the destruction of the filter paper, ignite the iridium strongly with the full heat of a Tirrill burner. After all carbon is burned out, cover the crucible with a Rose lid, preferably of quartz. Introduce into the crucible a stream of hydrogen, burning from the tip of a Rose delivery tube (a quartz tube is preferred). After five minutes remove the burner and a few minutes later extinguish the hydrogen flame by momentarily breaking the current of hydrogen. This is best done by having a section of the rubber delivery tube replaced by a glass tube, one end of which can easily be disconnected. Allow the iridium to cool in an atmosphere of hydrogen and then weigh as metallic iridium.

In commercial analysis no effort is made to correct the weight of iridium for small amounts of ruthenium. Correction, if desired, can be made according to the original directions of Deville and Stas. The correction for iron can be made according to the procedure given with the discussion of the analysis of the iron-iridium-platinum alloy.

Acknowledgments are made to Edward Wichers, under whose supervision the chemical work on the platinum metals was conducted, to R. P. Neville, who melted the alloys and prepared them in the form of wire, and to Florence J. Stimson, who made the spectrographic analyses of the iridium samples.

Summary

A study has been made of the analytical details of the Deville and Stas method for the determination of iridium in platinum alloys containing from 0.1 to 20% of iridium. Specially prepared alloys, made from highly purified metals, were used in the investigation. It was found that the concentration of nitric acid, the concentration of aqua regia, the proportion of lead, and the time and the temperature of the lead fusion can be varied over a wide range without affecting the determination. The observations of Deville and Stas that palladium and rhodium have no effect upon the determination and that ruthenium separates quantitatively with the iridium were confirmed. In addition, gold was found not to interfere. Iron separates nearly quantitatively with the iridium as observed by Deville and Stas. A method for the separation of iron from the iridium was tested and found to give satisfactory results. The loss in weight of crystalline iridium during the ignition periods is insignificant and the weight of crystalline iridium is not affected by heating and cooling in an atmosphere of

hydrogen. Spectrographic examination of samples of iridium from analysis showed that neither platinum nor lead was present in sufficient quantities to affect the determination. The iridium results tend to be low by a variable but usually small amount. One factor in this error is a slight solution of iridium by aqua regia. A modified procedure for the method is offered which combines the optimum conditions for speed and accuracy in the various details of manipulation.

A full report of this investigation including the actual experimental data will be found in a forthcoming publication of the Bureau of Standards.

SOLUBILITY. IX. METALLIC SOLUTIONS

By J. H. Hildebrand, T. R. Hogness and N. W. Taylor Received August 13, 1923

In a series of papers¹ appearing during the past seven years by the senior author and various collaborators considerable evidence has been presented to show that deviations from Raoult's law, and accompanying effects upon solubilities, can be predicted approximately for substances that are sufficiently non-polar, provided they do not tend to form compounds with each other. These deviations were correlated chiefly with differences in "internal pressure," as estimated by various criteria.

Metallic solutions offer a particularly inviting field for the application of a theory of solubility because a large amount of data is available and also because the metals differ among themselves in surface tension, compressibility, expansion, internal pressure and other characteristics far more than do the familiar non-metallic liquids, so that they offer a much more severe test of a theory than do most non-metallic solutions. For example, although but few non-metallic liquids, excluding water, are sufficiently unlike to yield two liquid phases, there are known no less than 47 metallic pairs which are incompletely miscible in the liquid state.

We do not have data upon the coefficients of compressibility and expansion for molten metals necessary for the calculation of their internal pressure by the expression $T_{\alpha/\beta}$, used in earlier papers, except for mercury, where the value is 13,200 megabars. This is several times as large as the values for the common non-metallic liquids, which explains, at least partly, their immiscibility with mercury. We may, perhaps, form a rough idea of the internal pressures of liquid metals from the values of α/β of their solid forms. Table I gives some figures of this sort taken

¹ Compare particularly This Journal, 38, 1452 (1916); 39, 2301 (1917); 41, 1067 (1919); 42, 2180 (1920); 42, 2213 (1920); 43, 500 (1921); 43, 2172 (1921); 45, 682 (1923). *Phys. Rev.*, 21, 46 (1923).

 $^{^{2}}$ α is coefficient of expansion; β of compressibility.

from a paper by T. W. Richards.³ We may also note that the tensile strengths of the metals are in somewhat the same order, nickel, platinum, iron and copper, for example, having high tensile strengths, lead, sodium, bismuth, etc., low strengths.

Table I

Relative Internal Pressures of Solid Metals Estimated from Expansion and

Compressibility

α	\times 10 6	$\beta \times 10^8$	α/β		$\alpha \times 10^6$	$\beta imes 10^8$	α/β
Nickel	42	43	98	Mercury (liq.)	180	395	46
Silicon	23	32	72	Lead	88	233	38

Aluminum	72	147	49				

The surface tension of molten metals may be expected to give a truer indication of the internal forces of the liquid than it does in the case of most compounds, because the molecules are simple and symmetrical and little or no orientation should take place in the surface. We may use the expression $\gamma/V^{1/3}$ or, where data are available, $E_{\sigma}/V^{1/3}$, where γ is the surface tension, V the molal volume and E_{σ} the surface energy. We have accurate measurements by Hogness⁴ for the surface tensions of mercury, bismuth, cadmium, lead, tin and zinc. Most values for the other metals are unsatisfactory and conflicting due partly, at least, to failure to prevent

the formation of an oxide film. Table II gives values for a number of the more important metals. On account of the difference in temperature the magnitude of $\gamma/V^{1/a}$ for the first five metals is much less than it would be if all of the metals in the table could be compared at the same temperature; accordingly, we are justified in concluding that their internal pressures would be found higher, at the same temperature, than those of the second group, zinc, bismuth, inclusive. It will be noted that the order is not very different from that given in Table I where, of course, crystal structure introduces disturbing factors.

The only other method applicable to the metals is the one using the heat of vaporization. Table III gives values of L/V, which again show approximately the same order, except that the most volatile, mercury and cadmium, are shifted considerably downwards. Table II, however, seems to be more closely correlated with our present knowledge of intermetallic systems.

We will now proceed to examine the solubility data to determine how far the arrangement in these tables corresponds to the mutual solubilities of the metals. We must be prepared, of course, to find solubilities greater than internal pressure differences alone may lead us to expect, due to compound formation, even though the attractions between the compounds may be insufficient to cause the separation in the solid state of any recognizable compounds. If the electron theory were more highly developed with reference to liquid metals we would doubtless be more prepared than we now are to predict compound formation and its attendant effects upon solubility. There is great need of enlightenment regarding the nature of intermetallic compounds.⁸

We will first consider the group of metals, zinc, cadmium, mercury, tin, lead, bismuth, which according to Table II have internal pressures

⁷ Hildebrand, THIS JOURNAL, 41, 1067 (1919).

⁸ However, compare Kraus, ibid., 44, 1216 (1922).

decreasing in that order. We have very accurate data by Taylor, on-cerning the activities, a, of these metals in a number of their liquid alloys, obtained by measuring e. m. f.'s of concentration cells. Taylor found that the pairs given below in Table IV give positive deviations from Raoult's law of the normal type. Writing Raoult's law as a = N, where N is the mole fraction, the deviation may be expressed by the value of $\log (a/N)$.

Table IV
Activity Coefficients in Various Alloys

		THE ELECTRICATE AND THE AT	MICOUS ILLIUOIS	
Allov	ŧ	$\Delta(E\sigma/V^{1/3})$		
moy	•	$N_{\rm Cd} = 0.1$	$N_{\rm Cd} = 0.2$	A(250/ V 79)
Cd-Sn	483	0.228	0.185	52
Cd-Pb	480	.455	.369	92
Cd-Zn	466	. 560	.373	106
		Log (a/?	V) for tin-	
		$N_{\rm Sn} = 0.1$	$N_{\mathrm{Sn}} = 0.2$	
Sn-Zn	466	0.460	0.274	158
Sn-Cd	463	.251	.185	52

The values of a/N for the three cadmium alloys are in the same order as the differences between the internal pressures of the components, using $E_{\sigma}/V^{1/s}$ to indicate the latter. It will be seen that the deviations are not, however, strictly proportional to these differences in internal-pressure. The same is true for the two tin alloys. Taylor also obtained results for cadmium-bismuth alloys. We might expect here to find a large deviation on account of their large internal-pressure difference. As a matter of fact, the deviation from Raoult's law is small, but of so irregular a type as to make its non-conformity to the internal-pressure theory not at all strange. The phenomena in this mixture are evidently rather complex.

Freezing point-composition diagrams are available which permit us to give the freezing-point lowering for a given solvent and a series of solutes at a fixed composition which, in the absence of "chemical" effects, should

place the metals in the order of their internal pressures. It is always most striking to consider the series obtained for the substances of highest and lowest internal pressure, for then there is no ambiguity as to the true order as there is when an element in the middle of the series is chosen for comparison, and when deviations do not differentiate the element of higher internal pressure from the one of lower. Table V, accordingly, gives the solubilities of bismuth and zinc in the series of metals falling between them in Table II also those of tin, in the middle of the series, whose

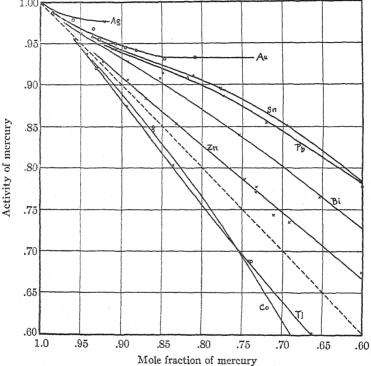

Fig. 1.—Activities of mercury in various amalgams

solubilities should show a maximum in the adjacent members. The figures were obtained from smooth curves drawn through the points given by the observers cited.

It will be seen that the agreement in the case of bismuth is perfect; for zinc it is nearly so, the positions of cadmium and mercury being reversed; for tin the only irregularity is its abnormally great solubility in bismuth, corresponding to the result found by Taylor, previously cited. Similar results are obtained with lead and cadmium.

The deviations of amalgams from ideality are shown by the vapor-pres-

sure measurements by the senior author and his collaborators, 15 summarized in the plot of a against N shown in Fig. 1. We see here more irregularity than in the other cases. With cadmium there is negative deviation, showing that the atoms of these elements attract each other to a greater extent than they attract their own kind. With zinc the deviation is positive but, just as in Table V, less than we might have expected, which may indicate the same sort of effect that is shown more obviously with cadmium, its nearer neighbor in sub-group 2 of the Periodic System. Again bismuth, which is below tin and lead in Table II, shows a smaller deviation than lead and tin. In brief, mercury seems to show more evidence than we have previously seen of greater attractions for certain other elements than internal pressures alone would lead us to expect. Cases of this sort multiply greatly with other systems to be considered in the following paragraphs. It is interesting to note the great deviations with silver and gold, which will be found in harmony with the positions of these metals in a later and more extensive table.

The construction of a more general table of internal pressures of metals is made difficult by the lack of accurate data concerning their physical properties in the liquid state, by the inferior accuracy of much of the solubility data, and by the frequency with which solid solutions and compounds occur, the former making the freezing-point data of less significance for our purpose, and the latter introducing a factor with which the simple internal-pressure theory is incompetent to deal. The table we have attempted to construct is, therefore, somewhat approximate in character and subject to later modification as our knowledge of the field is extended. In its construction we have been guided by what knowledge we possess of the physical properties of the metals, by the freezing-point data in cases where simple eutectics occur, by the existence of two liquid phases in many cases, showing extreme mutual insolubility, by the existence of solid solutions of simple type showing great similarity between the components, and by the Periodic System, which we have assumed to indicate the approximate positions of elements that belong to series already established. We have noted in general that internal pressure decreases from top to bottom of a group. Upon finding, for example, as in Table II, that internal-pressures decrease from zinc to mercury, we feel justified in assuming that the internal pressure of magnesium is higher than that of zinc.

The evidence is so large in volume but so inconclusive in many of its individual items, that it does not seem worth while to attempt to present it in detail beyond what is shown in Table VI, itself. This table lists the

cases in which binary alloys show either two liquid phases or solid solutions, and omits the compounds, which introduce complications rather than contradictions to the internal-pressure theory. The data have been derived from the usual sources, beginning with the Landolt-Börnstein "Tabellen."

TABLE VI INTERNAL PRESSURE SERIES FOR LIQUID METALS High ← Internal Pressure → Low Bi Na K Co Ni Al Cu Mg Ag Au Zn Cd Hg Sn Pb TI C High Cr Si i i i Mn i S Fe Co s S S Ni S S i Al Cu S s Mg Ag i Internal I PD Cd Hg s Sn i

^a The letters have the following significance: i, 2 liquid phases; S, complete solubility in the solid state; s, limited solubility in the solid state.

s

i

î

Each space in Table VI corresponds to the mixture of the two metals whose symbols are at the left-hand side and at the top, respectively. The diagonal is drawn through the intersection of each symbol with itself, so that the nearer a space is to this diagonal the closer are the two metals to each other in internal pressure. The portions of the table on the two sides of the diagonal are, of course, essentially identical, but the presence of both will be found convenient. Those combinations which yield two liquid phases are denoted by "i" (insoluble), those which yield a complete series of solid solutions by "S," and those showing limited solubility in the solid state are denoted by "s." Where the system has not been investigated, or where compounds have been found, the space has been left blank, so as not to complicate the table.

We must recall, first of all, that the internal-pressure theory cannot predict tendencies towards the formation of compounds, or abnormally great attractions between the atoms of unlike metals, so that negative deviations from Raoult's law, or even abnormally small positive deviations or, in other words, abnormally great solubilities, are not contradictory to the theory. All that can be expected is that insolubility cannot occur unless

there is sufficient difference in internal pressure, although even then it may not occur if tendency towards compound formation exists. Let us now examine the table with this in mind. It will be seen that there are no i's within a certain distance of the heavy diagonal, denoted by the dotted lines, indicating that there are no cases of insolubility in the liquid state among the metals adjacent to each other. A separation of at least five places is necessary. This may not seem very great, but reference to Table II will show that it corresponds to about 100% difference in internal pressure, almost as great as the entire difference from top to bottom of the table in our third paper 16 for non-metallic liquids. There would undoubtedly be found still more insoluble pairs if it were not for differences in boiling point, as between mercury and iron, which make it difficult or impossible to investigate the system. Even in such cases, however, the table is significant with regard to other phenomena, such as wetting, which likewise requires sufficiently great attractive forces between the two metals concerned. It is well known, for example, that pure mercury will not wet iron.

Turning to the consideration of solubility in the solid phases as an indication of probable likeness in the internal pressures of the liquids, when compounds are not formed, we find that 21 cases of solid solution are found in the spaces between the dotted line and the heavy diagonal, the region in which insolubility in the liquid form is absent, while but 17 cases occur outside this region, although the possible combinations in the other two regions are 57 in the former and 153 in the latter. In other words, solid solutions are known to occur in 37% of the possible combinations among metals within five places of each other in the internal-pressure series, while they are known among but 11% of the possible combinations of metals more than four places removed. If we consider metals removed less than eight places from each other, as compared with those eight or more places removed, giving equal numbers of possibilities in the two groups, we find 42 instances of solid solution among the former group and only 6 among the latter.

Table VI will be found useful, therefore, in predicting and correlating (a) the solubilities of metals in the liquid, and to some extent in the solid state; (b) the relative freezing-point depressions and apparent molecular weights; (c) the ability of a molten metal to wet solid metal.

It is expected, also, that it will prove very significant in connection with another phenomenon now under investigation in this Laboratory, namely, the initial overvoltage required to start the deposition of one metal upon another.

Whenever it shall prove possible to predict the chemical combinations of metals with one another, this knowledge, together with Table VI, or a

¹⁶ THIS JOURNAL, 41, 1067 (1919).

perfected form of it, should make it possible to correlate completely all of the intermetallic systems.

Summary

- 1. Various means of estimating the relative internal pressures of metals are discussed and tables are given.
- 2. Data are given showing the correlation between these tables and the behavior of binary metallic solutions.

BERKELEY, CALIFORNIA

EXTREMELY DRY LIQUIDS

By GILBERT N. LEWIS RECEIVED AUGUST 13, 1923

The very important discoveries of Baker¹ concerning the boiling points and other properties of highly desiccated liquids have opened a large and most promising field of physicochemical investigation. The startling results which have already been obtained have aroused some degree of skepticism, because of a suspicion that they were irreconcilable with fundamental thermodynamic principles; but I am convinced that no essential conflict exists, and that the chief observations which have so far been made not only may be interpreted thermodynamically, but also permit, with the aid of thermodynamics, some valuable predictions.

At first the experiments seemed to indicate that the removal of the smallest traces of water produced profound changes in the static properties of a liquid, such as might be explained by a large shift of inner equilibrium through the formation of a larger number of complex molecules from simple molecules. Smits² believes that such a change in equilibrium is thermodynamically possible and that it is in fact the explanation of the facts observed by Baker.

With this conclusion I can by no means agree. It is not absolutely prohibited by the laws of thermodynamics alone, but any one who will read the chapter on dilute solutions in the recent treatise on thermodynamics by Professor Randall and myself will see how little is required, besides the laws of thermodynamics, to prove Raoult's law for the infinitely dilute solution. For solutions of moderate concentration its approximate validity has been attested by hundreds of observations of the most varied sorts. The only marked exceptions occur when the solute dissociates, and then the activity of the solvent is diminished two, three, or more times as much as Raoult's law predicts, according as the solute molecule dissociates into two, three, or more molecules. Smits' hypothesis seems

¹ Baker, Phil. Trans., 79A, 583 (1888); J. Chem. Soc., 65, 611 (1893); 81, 400 (1902); 91, 1862 (1907); 101, 2339 (1912); 121, 568 (1922).

² Smits, Proc. acad. Sci. Amsterdam, 26, No. 3 (1923).

to imply changes in the activity of the solvent which are thousands or millions times as great as those given by Raoult's law.

Therefore, I think we must conclude that the mere removal of the last traces of water from a liquid could not appreciably change the existing equilibrium between the several molecular species, which might be assumed to exist. If water acts as a catalyst for the process of interchange between one molecular species and another, its removal could only serve to "freeze" the already existing state of equilibrium, by inhibiting further interchange between the various forms.

Such a behavior is well known in the case of liquid sulfur which contains two distinct molecular species known as S_{λ} and S_{μ} , which probably have the formulas S_{δ} and S_{δ} . When the liquid sulfur contains a trace of a substance very similar to water, namely ammonia, there is rapid interchange between the two species, so that equilibrium follows rapidly upon any change of condition, and the substance behaves like an ordinary pure liquid. But if the trace of ammonia is removed, the change from one species to the other is inhibited, and the sulfur behaves like a mixture. For example, it does not freeze at a fixed temperature, but the temperature changes during the process of freezing.

Let us consider, as a simple case, a hypothetical liquid consisting solely of simple molecules A and complex molecules of a single molecular species B; and let us assume that in the presence of moisture complete equilibrium is instantly established between A and B. Also in the vapor phase we may assume the same equilibrium to exist, although here the proportion of complex molecules might be negligibly small. Essentially, therefore, we may postulate a liquid consisting of a mixture of molecules A and B, and a vapor consisting merely of molecules A, all in equilibrium with one another.

Let us now imagine the removal of the last traces of water, or other catalyst, so as to inhibit the reaction A \longrightarrow B, in either direction. If this should be done at constant temperature, the vapor pressure will be the same as before, as well as the proportions of A and B in the liquid. But, if the liquid is now heated, more of the A molecules will escape into the vapor phase, and eventually the liquid will consist almost entirely of molecules B. In order to boil this liquid, a temperature must be attained at which either the B molecules themselves vaporize, or the rate of formation of A from B, in spite of the absence of catalyst, is rendered appreciable by the increase of temperature. Both of these processes might occur simultaneously.

This view of the phenomenon is in complete accordance with the latest experiments of Professor Baker,³ carried out in coöperation with Professor Smits. It was found that a sample of carefully dried benzene, similar

³ Baker, J. Chem. Soc., 121, 568 (1922).

to those which had already shown abnormally high boiling points, could be fractionally distilled, like a mixture of two independent components, the temperature of a thermometer placed above the boiling liquid rising steadily throughout the course of the distillation.

It is conceivable that in some cases the process of fractionation might not be observable and the dried liquid might almost immediately exhibit a constant high boiling point. If in the equilibrium mixture the proportion of A molecules were very small, their distillation from the dried mixture might not be noticeable, and the liquid could be heated directly to the new boiling point at which the vapor pressure of the B molecules would be equal to the atmospheric pressure, or at which the transition from B molecules to A molecules would be sufficiently rapid to give in the vapor phase a mixture of the two species, such that their total pressure would be equal to the atmospheric.

All these considerations lead to the interesting prediction that we shall find liquids with abnormally low boiling points as well as those with abnormally high boiling points. For thermodynamics teaches us that anything which inhibits the reaction A \longrightarrow B in one direction must also inhibit it in the other direction, and if, therefore, we could obtain a liquid containing only A molecules, it might have a much lower boiling point than the normal liquid. Thus if the normal vapor consists almost entirely of A molecules we should be able, by passing the vapor through phosphorus pentoxide and then condensing it, to obtain a liquid of very high vapor pressure and correspondingly low boiling point.

It seems likely that experiments with dried liquids and vapor may be conducted without exorbitant expenditure of time. In Baker's experiments the liquids employed had been dried over phosphorus pentoxide through a period of years, but it is to be observed that he depended in the main upon a process of diffusion, or accidental convection, to bring the moisture to the surface of the phosphorus pentoxide, and it probably was necessary to remove the moisture not only from the liquid and vapor but also from the surface of his glass vessel. By employing specially treated glass or some less hygroscopic material for the vessel, and by providing a circulating system which would rapidly carry the material to be dried through the phosphorus pentoxide, it should be possible to lessen very greatly the time required for drying. If such experiments prove to be successful, it should be possible to obtain results more quantitative than any so far secured. Such quantitative results would then be amenable to the same sort of precise thermodynamic treatment which has already been accorded to the case of liquid sulfur.4

While I have assumed for the sake of simplicity that the absence of water
See Lewis and Randall, "Thermodynamics," McGraw-Hill Book Co., New York,
1923.

inhibits a single reaction between a simple molecular species A and a more complex molecular species B, we may anticipate that the actual facts will often prove to be far more complicated than this. There is nothing in the chemical properties of some of the liquids investigated by Baker to lead us to expect any one complex molecule to show exceptional stability. Rather we should expect the formation of double, triple, quadruple molecules, and so on, to be evidence of a tendency in the condensed liquid phase toward the formation of indefinite aggregates, perhaps not entirely dissimilar to those which are produced in the process of crystallization, or at least due to forces similar to crystalline forces in that they operate only between molecules which are brought into close proximity. These, however, are questions which it is hardly worth while to discuss until further experimental information is at hand.

While at present the above explanation of the peculiar properties of dried liquids is the only one consistent with thermodynamics that seems at all plausible, it must be confessed that some of the results obtained by Baker still seem a little mysterious. According to this explanation, the static properties of a liquid, when it is freed from the last trace of water at a fixed temperature, should remain essentially the same. By a static property I mean such a one as the volume, and indeed Baker has found that the density of liquids is the same after thorough drying.

Whether surface tension is to be regarded as a static property would depend upon its method of measurement. If the liquid is allowed to rise in a capillary, a process occurs which is analogous to the formation of a new phase, and the surface tension so measured need not be the same in the dried and the undried liquid. In fact, the results indicate that the surface tension so measured is higher in the dried than in the undried liquids but further experiments in this direction should be undertaken.

Baker has found that the color of liquid nitrogen trioxide changes when the last trace of moisture is removed. This might of course be explained by attributing a very high coloring power to the water itself, but it is conceivable that color itself is not a static property, and that the absorption of light is accompanied by a chemical process which does not occur in the absence of a catalyst.

Perhaps the most puzzling observations made so far are those concerning the freezing points of the dried liquids. In every case the freezing points of the dried liquids have proved to be higher than those of the undried. We know little regarding the mechanism of crystallization. It might have been expected that complex molecular species would crystallize more readily than the simple molecular species, but on the other hand the liquid complex may not be of the sort that would fit into the crystal structure, and if so it would be the simple molecules which would most readily take part in the process of crystallization. This appears

to be the case. If a liquid is dried at a certain temperature to the extent of inhibiting the interchange between simple and complex molecules, and the temperature is then lowered, there will be a larger proportion of simple molecules than there would be in the equilibrium liquid at this lower temperature. The simple species would therefore have a higher activity in the dried liquid, and if it is this species that crystallizes, freezing will begin at a higher temperature than in the case of the normal liquid. However, as the simple molecules crystallize the freezing point should drop, and indeed fall ultimately below that of the undried liquid.

Finally, it is to be remarked that if it is found by experiment that circulation of a liquid through phosphorus pentoxide does not give the same results that are obtained when the liquid stands over phosphorus pentoxide; and if at the same time it is found that the static properties of the dried liquid do differ materially from those of the undried, we should be forced to an explanation which at present seems rather unlikely. It would be necessary to assume that a liquid in the ordinary state is not in the condition of highest stability, but tends to go over on quiet standing to another condition, just as a finely divided precipitate tends to form a single perfect crystal, or as a drawn wire tends to assume a coarsely crystalline condition. If the liquid on standing over phosphorus pentoxide really assumes a more stable state, then the original state could not be restored merely by the addition of a trace of water, but some agitation of the liquid would also be required in order to furnish the necessary energy for the conversion of the liquid into its normal, less stable, state. However, there seems to be nothing in the present stage of the experiments which would indicate the need for adopting so bizarre a conclusion.

Summary

The remarkable effects produced by removing the last traces of water from liquids promise to furnish information of great value concerning the liquid state. The only plausible explanation of these effects that seems consistent with thermodynamics rests on the assumption that water is a catalyst for processes between various molecular states, and that its removal merely inhibits such processes. If this explanation is correct the process of drying only "freezes" an existing equilibrium and (at constant temperature) cannot alter the static properties of the liquid. This leads to interesting predictions, for example, that liquids will be found that exhibit abnormally low, as well as abnormally high boiling points.

Equitable Trust Company of New York 10 Moorgate London, England [Contribution from the Chemical Laboratory of the Johns Hopkins University]

MANGANESE DIOXIDE IN THE CATALYTIC OXIDATION OF CARBON MONOXIDE¹

By W. A. WHITESELL AND J. C. W. FRAZER RECEIVED AUGUST 15, 1923

Introduction

The preparation of active catalysts for the oxidation of carbon monoxide has raised many questions as to the mechanism of the reaction. As method of preparation, choice and manner of incorporation of promoters, physical conditions of the substances, treatment before use, and conditions under which the reaction is carried out seem to be influencing factors, it is necessary to investigate them before any comprehensive theory can be proposed with a measure of assurance.

The discovery and preparation of these oxidation catalysts has been described in an article by Rogers, Piggot, Bahlke and Jennings² and also by Scalione and Merrill.³ Further work done in this Laboratory is described by Lanning⁴ and English.⁵ Lanning investigated the adsorption isotherms of preparations of manganese dioxide and the catalyst, Hopcalite, composed of manganese dioxide and silver oxide, to obtain an idea of their structure and the effect on adsorption of the method of preparation and treatment of Frémy oxide and the method of incorporation of the promoters. He found that the substances were highly porous, with a large internal surface, the size of the pores approaching molecular dimensions, that water vapor was taken up by physical adsorption and not as hydrate, its poisoning effect being due to a reduction of the active surface, and an alkaline solution did not reduce the surface but very likely changed its character. The Frémy oxide and promoter oxides were found to be oppositely charged, thus helping to give mutual dispersion to a high degree.

English studied the oxygen pressure over these substances at various temperature and found that the dissociation pressures indicated the existence of solid solutions.

Plan of Work

The present investigation was undertaken as a continuation of the study of the mechanism of the reaction, by preparation in different ways of various oxides such as manganese dioxide, silver oxide, cupric oxide, cobaltic oxide, lead dioxide, nickelous oxide, ferric oxide, etc., and the quantitative study of their effects, separately at first and then in mixtures, on the oxidation of carbon monoxide, hydrogen and other convenient, oxidizable substances. As manganese dioxide seemed to be the essential constituent in all previously prepared highly active catalysts studied in this Laboratory it was studied first, with the result that the investigation was given a rather

- ¹ The substance of this article forms a part of the dissertation submitted by W. A. Whitesell for the degree of Doctor of Philosophy at Johns Hopkins University and the work was carried out at the suggestion of J. C. W. Frazer.
 - ² Rogers, Piggot, Bahlke and Jennings, This Journal, 43, 1973 (1921).

different turn from that outlined, one result being the preparation of catalysts of manganese dioxide alone with equal if not greater activity than former oxide mixtures. They have functioned with 100% efficiency over a wide range of mixtures of carbon monoxide and air at temperatures as low as $-20\degree$.

Apparatus and Experimental Conditions

The apparatus and experimental conditions were essentially those described by Rogers, Piggot, Bahlke and Jennings.²

Experimental Part

The first experiment was made with a sample of commercial Frémy oxide which had been pressed, screened and dried in an air-oven overnight at 110°. As the results of this experiment determined in large measure the further course of the investigation, they will be given in some detail. The gases were first passed through soda lime and calcium chloride. The data are given in Table I.

Table I

Effect of Drying Temperature on Catalytic Behavior of Manganese Dioxide

Time of run, 1 hour. CO, 1 cc. per min. Air, 100 cc. per min.

Fresh sample.

				Time of r	un, 40 min.
Temp. °C.	Efficiency %	Temp. °C.	Efficiency %	Temp. °C.	Efficiency %
50	61	17	73	0	14.8
20	20	18	54	22	22.8
50	36	125	94	22	9.2
75	49	150	99	22	9.2
100	93	16	98	18	5.5

The temperature was then raised to 150° when considerable moisture came off of the catalyst and condensed in the exit tube. This was swept out with dry air. The temperature was then allowed to fall to that of the room when the efficiency was 95%. The hot zone appeared at the top of the catalyst bed but moved slowly to the bottom with a slight loss of efficiency in the course of 5 to 6 hours. While the gases continued to pass, the temperature was raised to 150° for several hours; the gases were then stopped and the tube cooled to room temperature. When the 1% mixture was then passed through, the hot zone appeared immediately at the top of the bed and practically complete oxidation occurred.

This series of runs brought out a number of points: (1) the poisonous effect of very small amounts of water vapor and perhaps of other adsorbed substances; (2) manganese dioxide as the primary substance in causing the oxidation, as had been previously thought; (3) manganese dioxide when suitably prepared is able to take up oxygen at a sufficiently elevated temperature to restore its activity at a lower temperature.

The material used in these experiments was the most active preparation of manganese dioxide previously described, and the results indicate that there is some temperature at which the rate of reoxidation is equal to the rate of oxidation of the carbon monoxide under the given conditions, that is some point at which this substance is just completely catalytic.

Inasmuch as impurities seem to play such an important part in the catalytic activity of many substances, it was thought that a purer sample of manganese dioxide might prove completely catalytic at ordinary temperatures. All previously prepared Frémy oxide had been made from potassium permanganate and sulfuric acid. It is difficult to wash sulfates from samples of manganese dioxide made in this way. As nitrates are less strongly adsorbed than sulfates it was thought the decomposition of permanganate in nitric acid might give a better product, and attention was turned in this direction. The idea proved very fruitful and resulted in the preparation of samples by methods which give very active catalytic oxides at temperatures as low as -20° . These methods are as follows.

- 1. Decomposition of potassium permanganate in concd. nitric acid. Powdered permanganate is poured into concd. nitric acid. Several hours are required for the decomposition of the permanganic acid and the mixture must be well stirred and cooled to prevent explosion. When these precautions are observed the decomposition goes smoothly and the danger is not great. A very black, finely divided, "sandy" product is obtained which can be washed and filtered rather easily. It must be pressed to secure necessary hardness as otherwise it dries to a sandy powder.
- 2. Retreatment of the commercial Frémy oxide. The moist oxide is treated with concd. nitric acid, diluted, washed, and filtered. It is best to allow the product to stand in contact with the acid solution for several hours and occasionally stir the mixture to keep the particles in suspension. This product dries fairly hard without being pressed, the precipitate being more gelatinous than that described in the preceding method.
- 3. Oxidation of manganese sulfate with potassium permanganate in nitric acid solution. Powdered permanganate or a concentrated solution is added to the equivalent amount of manganous sulfate in solution in nitric acid. This is a very rapid method of preparation, as precipitation of the dioxide is complete almost immediately. The product is of the same order of fineness as that described in the first method and must be washed, filtered and pressed in the usual way. The final washings are always made with distilled water.
- 4. Oxidation of manganous hydroxide precipitated from manganous sulfate. The hydroxide is precipitated from the sulfate solution by sodium or ammonium hydroxide and washed thoroughly. It may then be treated in two ways: (a) it may be dissolved in nitric acid and the solution evaporated,

the nitrate decomposing to the dioxide; care must be taken to avoid heating it too strongly as otherwise the product may become very dense and inactive, resembling the natural substance; the dry dioxide is then treated with concd. nitric acid, washed, and dried; (b) manganous hydroxide may be oxidized as far as possible in the air (this occurs most rapidly when the hydroxide is nearly dry) and then treated with concd. nitric acid which converts the brown hydrated oxide into a very black product that is washed and filtered in the usual way; it is unnecessary to press this material.

These samples are perfectly catalytic for the oxidation of carbon monoxide at ordinary temperatures, giving a sharp hot zone 0.5 cm. to 1.0 cm. wide at the top of the catalyst bed, which remains well defined after a continuous 20-hour run. When the drying tubes are removed the catalysts are rather rapidly poisoned by the moist gases and the activity is recovered extremely slowly at room temperature when the train is reconnected. It regains its activity immediately, however, when heated to about 150° in a stream of dry air. In fact, all the catalysts should be dried under these conditions before use. Above —20° pure carbon monoxide is oxidized quantitatively with corresponding reduction of the manganese dioxide to lower oxides of manganese. Using a 1 to 2% mixture of carbon monoxide in air, there is no induction period at the beginning of the reaction and complete oxidation occurs at once even at the low temperatures mentioned. An attempt was made to reduce the catalyst using carbon monoxide diluted with nitrogen, but so little reduction seemed to occur that it was investigated more closely, when it was found that the 2 to 3% of oxygen in the compressed nitrogen was being used up by the carbon monoxide, with little apparent reduction of the oxide occurring.

Adsorption of Carbon Dioxide and Carbon Monoxide

During the first experiment with a sample of preparation No. 1 the carbon dioxide was held back by adsorption so long that it was thought worth while to work out its isotherm at 0°.6 The data are given in the following table from which the curve has been plotted.

Table II
Adsorption of Carbon Dioxide by Manganese Dioxide at Zero Degrees

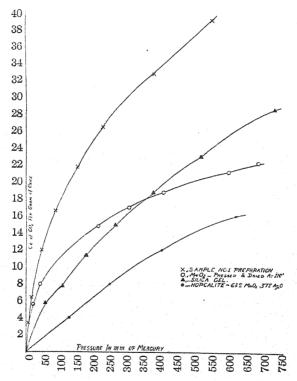

x/m = cc. Pressure of CO ₂ per Mm. of g. of oxide mercury	x/m = cc. of CO ₂ per g. of oxide	Pressure Mm. of mercury	x/m = cc. of CO ₂ per g. of oxide	Pressure Mm. of mercury
0.39 0.6	12.09	44.36	26.30	223.88
3.42 5.27	16.74	86.53	32.54	369.58
6.41 13.13	21.78	149.93	38.77	538.46

The sample had been dried at 180° for 3 hours in a stream of air over phosphorus pentoxide and then evacuated for $3^{1}/_{2}$ hours at 30° .

⁸ This work was done by Mr. Preston with the apparatus which is used in this laboratory for measuring adsorption.

Several of Lanning's curves are reproduced for the sake of comparison. These data show an unusually high adsorption of carbon dioxide by this particular sample, the curve lying entirely above that of silica gel even at the higher pressures. At lower pressures the amount taken up is twice that absorbed by silica gel or previous preparations of the sample or mixed oxides. This was rather surprising, as the sample was so "sandy" and non-gel-like in structure when precipitated. It thus shows a very large internal surface.

As it seemed likely that these catalysts were specific adsorbents for carbon monoxide, several attempts were made to test this experimentally.

Runs were first made to obtain an approximate idea of the rate of desorption of adsorbed carbon monoxide. Carbon dioxide was dried by calcium chloride and phosphorus pentoxide and then passed through a 3g. sample of the catalyst at -21° for 10 minutes at atmospheric pressure and at a rate of 30 cc. per minute. Then the train was closed at the exit end of the catalyst tube and left open to the carbon dioxide tank for 30 minutes. The train was then swept out with air at the rate of 30 cc. per minute until the atmosphere over the catalyst had been changed about twice, when bulbs containing 0.2034 N barium hydroxide solution were connected

with the apparatus and the amount neutralized was determined at various intervals

TABLE III

RATE OF	Desorption of	of Carbon	DIOXIDE FROM	MANGANESE	DIOXIDE

^a Only a trace was then coming over, so the temperature was allowed to rise.

From this catalyst carbon dioxide is, therefore, desorbed much more readily and completely than from Hopcalite as found by Lamb, Scalione and Edgar. In Hopcalite it is most likely held chemically to some extent by the more strongly basic oxide promoters. Adsorption of carbon monoxide was tried at -20°, -15°, 0° and 20° with practically identical results. The procedure was as follows. Carbon monoxide diluted with nitrogen freed from oxygen by bubbling through alkaline pyrogallol was passed slowly over the catalyst. The amount of nitrogen was gradually cut down until pure carbon monoxide was being passed, when the train was closed off at the exit of the catalyst tube and left open to the carbon monoxide tank for one hour. Then the train was swept out slowly with oxygen-free nitrogen until the tube was filled with nitrogen when the rest of the train was connected. Nitrogen was passed first at the temperature of the experiment until desorption was complete and finally with the catalyst at 100°. In all cases carbon dioxide appeared in the barium hydroxide tube at about the same rate as in the previous desorption run with carbon dioxide. It was hoped that any carbon monoxide adsorbed would be desorbed as such and thus appear in the second barium hydroxide tube. The same results were obtained by the use of moist as with dry nitrogen during the desorption. After the catalyst has been reduced sufficiently, the carbon dioxide comes off more slowly and at a higher temperature, indicating probably the formation of unstable carbonates by the lower oxides of manganese. No monoxide appeared in the second barium hydroxide tube, showing that oxidation of the carbon monoxide had occurred before desorption from the catalyst. This will be discussed later.

Effect of Carbon Dioxide on the Catalysis

Several runs were made with mixtures of carbon monoxide, carbon dioxide and air to test for a possible poisoning effect of the carbon dioxide. These tests were made with a 3g. sample of preparation No. 3. Some of the typical data are given in the following table, which is self explanatory.

Analyses were made at 30-minute intervals when equilibrium appeared to have been reached, as the results could be checked rather closely.

^b Only the slightest trace was then retained.

⁷ Lamb, Scalione and Edgar, This Journal, 44, 744 (1922).

Table IV

Effect of Varying Partial Pressures of Carbon Dioxide on the Catalytic Oxidation of Carbon Monoxide

Temp.	CO Cc./min.	CO ₂ Cc./min.	Air Ce./min.	Remarks
0	1	1	100	100% oxidation
0	1	100	100	100% oxidation
0	1	100	50	100% oxidation
-15	1	25	100	100% oxidation
-15	1	35	100	Trace of CO passed
-15	2	35	100	Several % of CO passed
-20	1.2	60	60	80% oxidation ^a
-20	1.2	60	100	50% oxidation

^a At this point the CO₂ was shut off and the air-CO mixture was passed for 5 minutes. At the end of this time 100% oxidation was occurring. CO₂ was again turned on.

Analytical Data

Analyses of samples for adsorbed alkali and available oxygen are given below, results being the average of several determinations on the various preparations described above.

P_2O_5 at 180° for several hours 2 MnO _{1.908} Sample dried in an oven at 120° 3 MnO _{1.906} Wet sample 3 MnO _{1.808} 0.27 Sample dried as No. 1 above	Sample	Mn: O	K₂O %	Remarks

Available oxygen was determined by the Bunsen method; this was found to be more rapid and satisfactory than the oxalic acid method. Total manganese was determined by means of sodium bismuthate, and potassium by precipitation with chloroplatinic acid.

Experiments with Hydrogen

In these experiments the water formed was collected in a weighed bulb of phosphorus pentoxide just after the catalyst tube. The total amount of hydrogen passed was obtained from the flowmeter readings. Inasmuch as the catalyst holds back water, especially at low temperatures, this method of procedure would not be so very satisfactory except for the fact that only slight oxidation appears to occur below 100–150°. Pure hydrogen does not reduce manganese dioxide at room temperature, judging from the absence of a heat effect. At 100°, 1 to 2% oxidation occurs and at 200° about 40 to 50%. Reduction of manganese dioxide by hydrogen begins at a higher temperature than in the case of Hopcalite, which con-

tains as high as 40% of the more easily reducible cupric oxide. This should make the manganese dioxide catalysts somewhat better for the removal of carbon monoxide from mixtures of this gas with hydrogen than Hopcalite under properly controlled conditions. Several qualitative tests have verified this.

Preparation of Cupric Oxide

Cupric hydroxide was precipitated from cupric nitrate solution with sodium hydroxide, and the precipitate washed thoroughly, pressed and dried. A sample of this oxidized 1 to 2% of a 1.0% mixture of carbon monoxide and air at room temperature but was not catalytic under these conditions.

Several experiments were made similar to those described for manganese dioxide to test for possible adsorption of carbon monoxide. Pure monoxide at the rate of 15 cc. per minute was passed over the catalyst for about 30 minutes at -20°, the train was swept out very thoroughly with nitrogen, and finally the barium hydroxide bulbs were connected. From an 8g. sample, between 0.8 and 4.0 cc. of carbon monoxide, calculated from the barium hydroxide neutralized, was desorbed and appeared in the second barium hydroxide tube. It was not expected that duplicate experiments on the same sample would agree closely, as the condition of the catalyst would be changed by its previous treatment. The carbon monoxide came off slowly at the low temperatures while no dioxide appeared in the first tube until nearly room temperature was reached. Then the adsorbed carbon dioxide came off until the final temperature of heating at 200°. From 8 to 20 cc. of dioxide was desorbed in this way from the 8g. sample during the different runs, showing that appreciable oxidation had occurred at the low temperatures, as was also shown by the appearance of carbon dioxide in the first tube during the time carbon monoxide was passing through the cupric oxide. Very likely, some carbon monoxide is oxidized in the process of desorption, so that the measured amount does not give the total monoxide held as such. Carbon dioxide is desorbed much less readily from this oxide than from the samples of manganese dioxide.

Discussion of Results

There are several points of interest which the present investigation has contributed in connection with the particular reaction studied, both to a knowledge of this reaction and the subject in general. From the results, it is clearly shown that manganese dioxide in Hopcalite mixtures is the initial cause of the oxidation, certainly at the lower temperatures. The active preparations are able to oxidize carbon monoxide extremely rapidly, either catalytically or at the expense of their own oxygen. The analytical data show that these active samples have a very low potash content, less than 0.5 to 1.0% of K₂O, while the partially active sample initially tried

contained very likely 3% or more, as has been shown by other investigators (English).⁵ These samples were otherwise quite alike as to physical structure. The commercial sample after partial reduction was able to take up enough oxygen at an elevated temperature to restore its activity for a time. When it was more completely freed from potash it was able to take up oxygen fast enough to become completely catalytic at lower temperatures. This points to a mechanism of alternate reduction and oxidation of the catalyst. The efficiency is quite evidently dependent on the nature of the active surface as well as on its extent. A sample of preparation No. 4, for example, which had been ignited too strongly, on evaporation became quite dense, resembling the natural product and was entirely inactive, although alkali free. This meant a packing and possibly a total change of structure of the material and a reduction and probably alteration of the nature of the surface but without destruction of the porous structure. The "promoted," Hopcalite, sample is active, although it still may contain 1.74% of K₂O. To state with certainty the effect of the cupric oxide on the mixture it would be necessary to have data on a sample of manganese dioxide containing this amount of alkali. If the alkali is all associated with the manganese dioxide, as the Hopcalite is 60% of manganese dioxide, the latter actually contains 2.90% of K₂O. As a sample of manganese dioxide containing this much impurity would hardly be completely catalytic alone it seems that the cupric oxide does show promoter action. It is still possible that it cuts down the adsorbed alkali or affects the way it is held so that its poisonous effect is annulled. On the other hand, both cupric and manganous ions are catalysts in other oxidation processes. These adsorbed ions may, therefore, act as oxygen carrier to the carbon monoxide. The activity seems to be intimately connected with the ability and rapidity with which the substance can take up oxygen, which may be caused by the rapid shifting of electrons in manganese atoms, so the poison or promoter may affect the stray field or the atomic or molecular configuration of the catalyst itself.

Attention is next called to the manganese-oxygen ratios in the samples. Here as in the previous investigations the loss of oxygen by manganese dioxide is noticed even at room temperatures and in a wet sample, indicating a dissociation pressure of oxygen in the pure manganese dioxide greater than the partial pressure of the oxygen in the atmosphere. English⁵ finds that these oxides behave as solid solutions, the oxygen pressure varying with the composition of the mixture; this is similar to the conclusions of Sosman and Hostetter⁸ in the case of the oxides of iron. The action of promoters and poisons may be due to their presence as constituents of such solutions. The fact that the mixtures lose oxygen at room temperature shows that they have a dissociation pressure greater than the oxy-

⁸ Sosman and Hostetter, This Journal, 38, 807 (1916).

gen in the air, and the activity because of this is greatly increased by the fineness of division of the particles. The molecules are at a point where electron changes occur with great rapidity and oxygen evaporates and condenses as readily as molecules do in the case of a liquid at its boiling point.

Water being a highly unsaturated substance with a strong field is readily adsorbed and is, therefore, a poison for many catalytic reactions. Carbon monoxide is often thought of as an unsaturated compound, but it has a weak stray field and molecules of stable configuration, as evidenced by its low boiling point and other physical properties. Yet in the catalysis of the reactions, $2H_2 + 0 \Longrightarrow 2H_2O$ and $N_2 + 3H_2 \Longrightarrow 2NH_3$, carbon monoxide is a poison because it is rather strongly adsorbed, although in the latter case the poison effect may be due to the formation of water by the reduction of the carbon monoxide by hydrogen. It reduces most metallic oxides at a lower temperature than hydrogen and in the case of manganese dioxide this difference in temperatures of reduction seems to be especially large. It is known that manganese dioxide catalyzes the reaction, $O_2 \Longrightarrow$ O + O, which fact together with the reasons outlined previously would account for the increased activity of the oxygen. The low temperature of oxidation of carbon monoxide as compared with that for the oxidation of hydrogen points, however, to the activation of the carbon monoxide as an important factor. Taylor and Burns9 point out the importance of specific adsorption in the case of metallic catalysts. They say,

"Some metals, which show specific adsorption for carbon monoxide hold it very tightly. Maximum catalytic activity does not occur at temperatures at which maximum adsorption is shown. Free evaporation of reactants and resultants is necessary. It seems likely that any substance which can distort or disarrange the stable configuration of the molecule or arrangement of outer shell electrons will greatly increase reactivity."

The rapidity of oxidation of carbon monoxide (the time of contact is of the order of 0.01 second, comparable to that in the oxidation of ammonia) shows that the monoxide is not held very tightly as such. If it were, it would be its own poison. Failure to effect desorption of carbon monoxide as such from manganese dioxide points to a rapid rearrangement and reaction. That carbon monoxide may be adsorbed is shown by the experiments with the less active cupric oxide. The course of the reaction would be, then, adsorption and simultaneous oxidation of carbon monoxide by the catalyst; desorption of the carbon dioxide or its adsorption by capillary condensation in case the catalyst were not already saturated; and finally reoxidation of the catalyst. The carbon dioxide is inert and chemically inactive and therefore does not poison the catalyst except by mechanically covering the surface and preventing contact of the reactant with the catalyst surface.

⁹ Taylor and Burns, This Journal, 43, 1273 (1921).

The range through which molecular forces may act is variously put at 1 to 1500 $\mu\mu$. Assuming it to be near the larger limit it might not be necessary to postulate actual contact of the gas molecules and catalyst surface. The field of force might be strong enough at some distance to bring the gases into a reactive condition. Adsorbed poisons would modify or annul this stray field. The effect of temperature in altering the distance through which these molecular forces may exert themselves might conceivably have considerable influence on the temperature coefficients of chemical reactions.

Since this work was completed, two articles have appeared by Benton, ¹⁰ one on "Adsorption of Gases by Oxide Catalysts," and the other on "Adsorption and Catalysis in Carbon Monoxide Oxidations." This author proposes a mechanism for the reaction practically identical with that arrived at as a result of this investigation. This would indicate that oxidation of the carbon monoxide was caused by the oxygen of the catalyst, and that subsequently oxygen was taken up by the catalyst.

He described his manganese as a product of "high purity" and low density. Such a sample should have been very active according to the results recorded in the present investigation, but his results show that this was not the case and it still contained, very likely, several per cent. of impurities. The experience of the present writers has been that each preparation must be treated as a special case without assuming too much from previous work done on other preparations, unless accurate analytical data are available for comparison.

Summary

- 1. Methods for the preparation of active samples of manganese dioxide for the catalytic oxidation of carbon monoxide have been described.
- 2. Analytical results show that the amount of impurities, such as adsorbed alkali, plays an important part in the activity of these catalysts.
- 3. Experiments show a considerable temperature interval between the points required to oxidize hydrogen and carbon monoxide by these samples of active manganese dioxide.
- 4. A dynamic method for measuring the adsorption of carbon monoxide by manganese dioxide shows that it is desorbed from the catalyst as carbon dioxide.
 - 5. A mechanism for the reaction is proposed and discussed.

THE FREE ENERGY OF DILUTION AND THE ACTIVITY OF THE IONS OF HYDROGEN IODIDE IN AQUEOUS SOLUTION¹

By J. N. Pearce and A. R. Fortsch Received August 16,1923

The free-energy decrease accompanying the transfer of one mole of salt from any concentration c_2 to concentration c_1 is most conveniently determined by the electromotive-force method. The free-energy decrease $(-\Delta F)$ and the electromotive force E are related to the activities of the ions by the well-known thermodynamic expression, $(-\Delta F) = e.m.f. =$ $RT \log \frac{a_2^+ \cdot a_2^-}{a_1^+ \cdot a_2^-}$, where a_2^+ , a_2^- and a_1^+ , a_1^- represent the activities of the cation and anion in concentrations c_2 and c_1 , respectively. The other symbols have their usual significance. If we now choose one solution so dilute, that we may assume the activity product, a_1^+, a_1^- , equal to the product of the concentrations of the ions as measured by conductance, then it is possible to calculate the product of the activities of the ions, a_2^+, a_2^- , at any other concentration c_2 from purely electromotive-force data. If we assume with MacInnes2 the hypothesis of the independent activity of the ions and also that in any solution of potassium chloride the activities of the potassium and chloride ions are equal, the expression $\sqrt{a_{K}^{+}.a_{Cl}^{-}}$ gives us directly the activity of either of these ions. Likewise, having determined by electromotive force the activity product of the ions for a given concentration for any other binary electrolyte containing either a potassium or a chloride ion, the ratios, $(a_{\rm M}^+, a_{\rm Cl}^-)/a_{\rm Cl}^-$ or $(a_{\rm K}^+, a_{\rm X}^-)/a_{\rm K}^+$ give immediately the activities, $a_{\mathbf{M}}^{+}$ or $a_{\mathbf{X}}^{-}$, respectively.

Adopting this procedure, Pearce and Hart³ have found that the activities of the chloride and bromide ions are equal for equal concentrations of their binary salts. It should be said in passing that we are not unmindful of the excellent work of Lewis and Randall.⁴ These men have calculated the same results for these ions from freezing-point and vapor-pressure data. For the sake of brevity, however, the discussion of their work as well a that of others will be omitted at this time. The present paper deals with a study of the free energy of dilution and the activities of the ions in aqueous solutions of hydrogen iodide.

Apparatus and Materials

The cell used was similar to that described by Linhart.⁵ The platinum wire anode

¹ This paper contains the essential parts of a dissertation by Dr. A. R. Fortsch.

² MacInnes, This Journal, 41, 1086 (1919).

was tightly packed with fine, electrolytically deposited crystals of metallic silver and then covered with a layer of silver iodide. The silver iodide was prepared by precipitation from carefully recrystallized silver nitrate and potassium iodide; it was then washed with conductivity water until the washings gave no test for iodides and finally stored under conductivity water. Every possible care was taken throughout the work to exclude light, and in no experiment did the precipitate darken perceptibly. Two hydrogen electrodes were placed in each cell. These consisted of large pieces of platinum gauze heavily coated with platinum black. The hydrogen iodide was made by passing hydrogen sulfide through an aqueous suspension of pure resublimed iodine. The solution was boiled to remove the last traces of hydrogen sulfide and then fractionally distilled. The fraction of constant boiling point was stored over a small quantity of red phosphorus and was freshly distilled in a current of pure hydrogen when needed.

In making the solutions of hydrogen iodide, approximately the required volume of the constant-boiling acid was added to a given volume of cooled, previously boiled conductivity water. The cell and contents were repeatedly rinsed with the solution and then filled to the proper volume, the electrodes were inserted and the cell was placed in a large constant-temperature oil-bath. Hydrogen, obtained by the electrolysis of a strong solution of sodium hydroxide, was first passed through a strong alkaline solution of pyrogallol, then through concd. sulfuric acid and, finally, through saturator bulbs, containing an acid of the cell concentration into the cell. In preliminary experiments it was found that the rate of bubbling may be varied between 30 and 250 bubbles per minute without affecting the constancy of the voltage readings. The rate of flow was limited in every experiment to about 60 bubbles per minute. The time required for the cell to attain equilibrium under the precautions necessary varied from 4 to 8 days, depending on the concentration. The exact molal concentration of the hydrogen iodide was determined gravimetrically as silver iodide after the cell potentials had been read.

Accuracy of Method All electromotive-force data given in the following tables are the mean

values for at least two different arrangements of the cell. Readings were taken on the two hydrogen electrodes independently and unless the variation between the two was less than $0.04~\rm mv$. the process of preparation was repeated. All potential readings were corrected by applying the usual formula: $E = \frac{0.0001983T}{2}\log\frac{760}{x}$, where E is the correction voltage, T the absolute temperature and x the partial pressure of the hydrogen above the solution. All barometer readings were from a standard precision barometer and were corrected for latitude, altitude and temperature. The electromotive forces were read at 25°, 30° and 35°, in the order named, and then to ascertain whether any changes had occurred within the cell during the experiment the temperature was lowered to 25° and the readings were again taken. In only one cell (0.24608~M) did the initial and final readings at 25° differ by more than a few tenths of a millivolt.

In the preliminary work it was observed that the potential readings begin to vary considerably when the electrodes were allowed to remain in the solution for more than 60 hours. Upon removing the electrodes, allowing them to stand in nitric acid for an hour or more and then replatinizing them. readings could be duplicated indefinitely to within 0.10 mv. At 0.12972 M a slight opalescence was observed on adding a soluble chloride to the nitric acid wash water. At concentrations greater than 0.24608 M the amount of silver deposited on the electrodes became considerable and no consistent readings were obtainable.

The potential readings were made on a standard potentiometer, the reference standard being a certified Weston cadmium cell (1.01871 volts at 23°). The temperatures were accurately controlled to $\pm 0.03^{\circ}$.

Experimental Part

Table I gives the final values for the electromotive forces of the cells at various concentrations and at 25°, 30° and 35°.

Table I

ELECTROMOTIVE FORCES OF THE CELLS

Holder Agilag

	112 111, 1181 118							
1000 g.	E_{25} volts	E_{30} volts	E_{35} volts					
0.24608	-0.06905	-0.06864	-0.06829					
.12972	03615	— .03556	03531					
(.10000)	— .02273	02202	02162					
.07914	01210	01128	— .01073					
.05049	+ .01006	+ .01128	+ .01235					
.01981	+ .05735	+ .05931	+ .06083					
.01045	+ .08825	+ .09060	+ .09262					
.00505	+ .12417	+ .12707	+ .12964					
(.00500)	+ .12453	+ .12744	+ .13991					

The values of E (in parentheses) for the concentration 0.005 M were obtained by assuming E as a quadratic function of c, using the three concentrations 0.01981, 0.01045 and 0.00505. Those for the 0.10 M were obtained in a similar way by using the concentrations 0.24608, 0.12972 and 0.07914. It will be noted that a change of sign occurs between the concentrations 0.07914 M and 0.05049 M. This is due doubtless to the fact that silver iodide is extremely insoluble; a small concentration of hydrogen iodide is sufficient by reason of the common ion effect to reduce the concentration of the silver ion to such an extent that the potential of the cell is reversed.

The free-energy decrease $(-\Delta F)$ accompanying the cell reaction was obtained by multiplying the electromotive force of the cell by 96494. These values have been calculated for the various cells at the three temperatures, and from them we have calculated the temperature coefficients of free energy, α and β . The decrease in heat content $(-\Delta H)_{25}$ was computed by means of the relation: $(-\Delta H)_{25} = (-\Delta F)_{25}(1-298.09\alpha)$. This is obtained by substituting the expression for $(-\Delta F)$ as a function of the

temperature in the fundamental thermodynamic equation, $\frac{d}{dT}\left(\frac{-\Delta F}{T}\right) =$

 $\frac{-\Delta H}{T^2}$, performing the differentiation indicated and rearranging terms. The data thus assembled are collected in Table II.

Table II
The Free-Energy Decrease and the Heat-Content Decrease Accompanying the
Cell Reaction at 25°

1000 g.	$(-\Delta F)_{25}$ joules	α.10 ⁶	β.10 ⁷	$(\Delta H)_{25}$ joules
0.24608	- 6663	-1277	+ 177	-9199
.12972	- 3488	- 4211	+1886	-7867
(.10000)	- 2193	- 7609	+2726	-7168
.07914	- 1167	-16151	+4453	-6789
.05049	+ 970	+25909	-3092	-6524
.01981	+5534	+ 7608	-1539	-7016?
.01045	+ 8515	+5699	- 748	-5953
.00505	+11982	+ 4950	- 531	-5699
(.00500)	+12016	+ 4950	- 549	-5715

It will be noted that the values of α and β change sign between the concentrations 0.05049 M and 0.07914 M. At some concentration between these the electromotive force and hence the free-energy decrease are zero. Thus, the values of α must change from a small negative number to an infinitely large negative number on the one hand, and from an infinitely large positive to a small positive number on the other hand. In other words, the coefficient α changes sign by passing through infinity. The negative values of $(-\Delta H)_{25}$ decrease regularly with increasing dilution.

The decrease in free energy attending the transfer of one mole of hydrogen iodide from any concentration c to one exactly 0.005 M was obtained by the algebraic addition of the $-\Delta F_{25}$ values given in Table II. By sub-

stituting these values in the expression,
$$-\Delta F_{25} = RT \ln \frac{c_2^2 (\alpha_2^+, \alpha_2^-)}{c_1^2 (\alpha_1^+, \alpha_1^-)}$$

and assuming that the value of (a_1^+, a_1^-) for 0.005~M hydrogen iodide is the same as that determined by Noyes and MacInnes⁶ for the same concentration of hydrogen chloride, namely, 0.9312, we have calculated the product of the activity coefficients of the two ions at the remaining concentrations. Lewis and Randall⁴ have used as the basis of their values for hydrochloric acid a method of extrapolation described by Linhart.⁵ The value of the product of the activity coefficients for a 0.005~M solution is 0.8968. We have calculated the product of the activity coefficients using both values; the results are assembled in Table III.

From the data of Noyes and MacInnes⁶ on hydrochloric acid it may be noted that there is a minimum value for the activity-coefficient product at about 0.5 M. From this investigation we are led to the conclusion that the same type of variation is exhibited by the activity coefficients of hydri-

⁶ Noyes and MacInnes, This Journal, 42, 239 (1920).

TABLE III

The Free-Energy Decrease Attending the Transfer of one Mole of Hydrogen Iodide from Concentration ϵ to 0.005 M, and the Products of the Activity Coefficients of the Ions

odic acid, but that the minimum occurs at a lower concentration, about 0.11 M. We next plotted the activity-coefficient products against the concentrations on a large scale and read from the smooth curve the activity products at round concentrations. The geometric mean activity coefficients of the ions have been calculated and are tabulated for comparison along with the corresponding coefficients of the ions of hydrochloric acid as calculated on the assumptions of Noyes and MacInnes and of Lewis and Randall in Table IV.

Table IV
The Geometric Mean Activity Coefficients at Round Concentrations

1000 g.	HI (exp.)	HCl (N—M)	HI (exp.)	HCl (L—R)
0.005	0.965	0.965	0.947	0.947
.010	.937	.932	.920	.924
.020	.901	.899	.886	.894
.030	.893	.880	.877

.100	.862	.847	.846	.814
.200	.849	.796	.834	.783

It is evident from the data here given that the activity coefficients and the activities of the iodide and chloride ions are equal for any concentration of their acids up to $0.05\,M$. It is interesting to note that the activity coefficients, based on the assumption that the activity coefficient of $0.005\,M$ hydrochloric acid is 0.965, agree closely with the fractional ionization of uni-univalent salts of the type KCl as calculated by Randall. In regard to the different values of the activity coefficients obtained by using different values for the coefficient of the dilute solution arbitrarily chosen for reference, it is apparent that the difference lies mainly in the value of the reference chosen. Any error in either standard would influence the entire series of activity coefficients.

⁷ Randall, This Journal, 38, 790 (1916).

Summary

- 1. The electromotive forces of cells of the type, $H_2 \mid HI(c)$, $AgI \mid Ag$, have been measured at 25° for various concentrations of hydrogen iodide.
- 2. The free-energy decrease and the heat-content decrease attending the cell reaction have been calculated.
- 3. The free-energy decrease accompanying the transfer of one mole of hydrogen iodide from the various concentrations to a concentration exactly $0.005\ M$ has been computed. From these values we have calculated the geometric mean activity coefficients of the ions of hydrogen iodide, and we have found that for concentrations up to $0.05\ M$ these coefficients are practically equal to the corresponding coefficients for hydrogen chloride at the same concentrations. Obviously, the activities of the iodide and chloride ions are equal when in equivalent concentrations of their salts.

THE DIFFUSION OF HYDROGEN THROUGH METALS1

By Horace G. Deming and B. Clifford Hendricks

RECEIVED AUGUST 29, 1923

Deville and Troost,² Graham,³ Sieverts,⁴ and Charpy and Bonnerot⁵ have studied the diffusion of hydrogen through platinum, iron, palladium, copper and nickel. The rate of diffusion, found to be very different for different metals, was shown to increase rapidly with increasing temperature, but the results obtained were hardly more than qualitative, and were not expressed in terms that may be compared with recent work. More accurate data have been obtained by Schmidt⁶ and by Holt⁷ on palladium, by Richardson and coworkers⁸ on platinum, and by Edwards and Pickering⁹ on rubber, the rate of diffusion of hydrogen through these substances at different temperatures being shown graphically. In the work described in the present paper a method has been developed that permits the rate of diffusion of gases through metals to be determined under more precisely controlled conditions than has previously been possible; and preliminary

results have been obtained for the rate of diffusion of hydrogen through nickel, copper, lead, zinc and aluminum.

Apparatus

In designing the apparatus to be used in this work it seemed desirable: (1) that the metal to be tested should be in the form of flat sheets or discs; (2) that one metal should be easily interchangeable for another at the end of a series of tests; (3) that diffusion should be limited to a definitely measurable area; (4) that the temperature over this area should be as uniform as possible; (5) that the apparatus should be usable up to temperatures of at least 1000°. The method finally developed met these five requirements quite perfectly, the essential parts of the "diffusion-unit" being as shown in Fig. 1.

The metal to be tested was a disk D, about 9.5 cm. in diameter, of any desired thickness. This was clamped between two cylindrical steel blocks XY, each delimited

by two concentric circular knife-edges AB, and centered by a steel ring C. Bolts MM', passing through insulating soapstone blocks S and an asbestos ring V, served to draw the circular knife-edges against the metallic disk, but not necessarily tight enough to make a gas-tight joint.

Each steel block was tapped to receive three threaded steel tubes, joints being made gas-tight with metaphosphoric acid. Through one of these tubes, H, hydrogen, purified as described hereafter, was admitted to the shallow cavity in the upper surface of the lower steel block Y. The annular channel between the two knife-edges of this block was connected, through L with a vacuum pump, in order that any hydrogen leaking outward past the inner knife-edge might be immediately removed. The area of metal exposed to diffusion was thus definitely restricted to that circumscribed by the inner knife-edge of the lower block. This was 46.03 sq. cm. at 20°, becoming greater by about 0.2% at 100°, 1.2% at 500°, and 2.6% at 750°, on account of the expansion of the steel.

Any hydrogen diffusing through the given area of the metallic disk D was immedi-

ately swept out through F by a current of nitrogen which was admitted to the upper block through the tube E and the capillary opening P. This nitrogen also had direct access to the annular space N between the two knife-edges of the upper block and, being there maintained under a slight pressure, served to prevent the loss by leakage outward under the knife-edges of the upper block, of any hydrogen that might have diffused through the disk. By maintaining a brisk current of nitrogen through the upper portion of the apparatus it was possible to keep the hydrogen there at a very low concentration, and thus make sure that no appreciable part of the hydrogen diffusing through the disc should afterward be lost by being absorbed by the steel of the upper block or outlet tube.

The opening G served to admit a Chromel-Alumel thermocouple; K served as an outlet, when the chamber in the lower block was swept out with nitrogen, in preparing for a "blank determination." Connections were made outside the furnace in which the steel "diffusion unit" was heated, by tinning the steel tubes, and soft-soldering to platinized Pyrex glass. The soldered joints were water-cooled at higher temperatures.

Surrounding the steel blocks of the "diffusion unit" was a heating unit. The thermocouples, calibrated at the freezing points of tin, zinc, antimony and sodium chloride, 11 showed the temperature within the two steel blocks to be uniform, within 5°.

Connected to the tube F, Fig. 1, was a small electrically-heated furnace, containing copper oxide. This was kept at a dull red heat; and the water vapor, produced by oxidation of the hydrogen which had diffused through the metallic disk, was absorbed in phosphorus pentoxide and weighed.

Manipulation

In beginning each experiment, the "diffusion unit" was first heated slowly to the desired temperature, with the shallow chambers above and below the metallic disk filled with nitrogen, to prevent oxidation. Then a "blank determination" was made, to determine whether there was any change in the weight of the U-tubes containing phosphorus pentoxide when no hydrogen was being admitted to the "diffusion unit." In practice, an increase in weight of 1 or 2 mg. was obtained in the blank test, in several hours' run. Hydrogen was admitted to the lower chamber after preliminary blanks were secured, and measurements were then made at various temperatures which gradually approached the melting point of the sample under examination. Finally, the hydrogen in the lower chamber was displaced by nitrogen, in order that the series of measurements might be concluded with a second "blank determination."

The hydrogen was generated in a Kipp apparatus from zinc and dil. sulfuric acid, and purified by being passed successively through an alkaline potassium permanganate solution, a 5% silver nitrate solution, concd. sulfuric acid, a small electric furnace charged with copper turnings and heated to about 350°, and U-tubes containing soda-lime and calcium chloride. The nitrogen was obtained from a commercial cylinder, and was purified by being passed through an apparatus containing ammoniacal ammonium chloride solution to absorb oxygen.¹³ From this it entered a gasometer, displacing dil. sulfuric acid, and was subsequently purified by being passed through concd. sulfuric acid, a furnace containing copper oxide and copper

¹⁰ McKelvy and Taylor, This Journal, 42, 1366 (1920).

¹¹ Bur. Standards Circ., 35 (1919).

¹² In the results submitted, these "blank" values, which are probably due to moisture from the copper oxide and from hydrogen adsorbed by the steel blocks of the diffusion units, are not satisfactory. This is one procedure of this research which the junior author hopes to refine in work now under way.

¹⁸ Badger, J. Ind. Eng. Chem., 11, 1052 (1919); 12, 161 (1920).

turnings heated to about 350°, and finally through U-tubes containing soda-lime and calcium chloride.

Experimental Results

Aluminum.—The aluminum used was a disk of commercial sheet metal, 0.637 mm. thick. After a few preliminary determinations, to standardize the manipulation, the data given in Table I were obtained. The water collected in the blank determinations, expressed in milligrams per hour was, on the average, practically the same as when hydrogen was admitted to the lower chamber of the "diffusion unit." Thus, aluminum appears to be totally impermeable to hydrogen at temperatures as high as 550°. The hydrogen appeared to produce no great alteration in the physical properties of the aluminum, except that minute blisters appeared, forming parallel streaks across the surface of the metal, doubtless due to bubbles of gas trapped just beneath the surface, and elongated during rolling.

Average blank, 0.35 mg. of water per hour.

thickness of 1.643 mm. Discarding a few experiments in which the time of diffusion was only two hours or less, the data obtained are given in Table II. The figures in the last column are obtained by correcting the data in the fourth column for the average rate of collection of water in the two blanks. The area exposed to diffusion in the temperature range studied was taken as 46.7 sq. cm.

Assuming the rate of diffusion to be inversely proportional to the thickness of the metal disk (Fick's law) we may calculate the specific diffusion rate of hydrogen through zinc, expressed in mg. per hour per sq. cm. area per mm. thickness, to be about 0.0012 at 375° .

Lead.—A disk of commercial soft lead was used, with an average thickness of 0.862 mm. The data obtained are given in Table III. The two preliminary blanks were unusually high, presumably due to incomplete drying of the copper oxide in the combustion furnace. If we assume that the first few determinations are vitiated by the same cause, we nevertheless have evidence from the remaining data of an extremely slight permeability of lead to hydrogen. We may calculate the specific diffusion rate of hydrogen through lead (mg. per hour per sq. cm. per mm. of thickness) to be not more than 0.001.

Table III

DIFFUSION OF HYDROGEN THROUGH LEAD

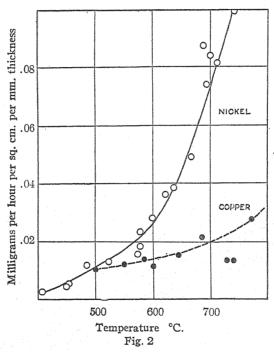

Disk, 0.862 mm. thick. Area exposed to diffusion, 46.7 sq. cm.

1.25	295	0.3	.2	Blank
1.0	300	.0	.0	Blank

Blank correction in this series taken as 0.2 mg. of water per hour. Average rate of diffusion in three final determinations, 0.0009 mg. of hydrogen per sq. cm. per hour at temperatures around 265° .

Copper.—The data obtained with copper at first were very erratic. The metal appeared to be much more permeable to hydrogen than any of those previously examined. But after the metal had been exposed in the furnace to alternate heating and cooling for a number of hours, the rate of diffusion suddenly seemed to increase enormously. Microscopic examination showed a decided increase in the size of the metallic crystals, and the development of intra-crystalline cracks, as a result of the heating. In addition, the disk was perforated by several minute holes immediately above the hydrogen inlet.

It was presumed that a part of the difficulty might have been due to the reduction, by the hydrogen, of the cuprous oxide which is an impurity in ordinary copper. For this reason subsequent tests were made on sheet copper¹⁴ which had been made by cold-rolling cathode copper. Care was also taken to begin the observations at a high temperature, and to make successive determinations at lower and lower temperatures, without permitting the furnace to cool until the end of the series. In this way the alternate contraction and expansion of the copper disk, caused by repeated

heating and cooling, were avoided, and the tendency to form intra-crystalline cracks was minimized. Under these conditions the data given in Table IV were obtained. A rapid increase in permeability with increasing temperature is indicated, as shown graphically in Fig. 2. The specific diffusion rate of hydrogen through copper (mg. per hour per sq. cm. per mm. of thickness) may be calculated to be about 0.028 at 770° and about 0.011 at 500°.

Nickel.—Of the five metals studied, nickel was the easiest with which to work. The sample was of electrolytically refined nickel, 16 and had an aver-

results obtained, selected impartially from a much larger number of determinations, are given in Table V. Here again a rapidly increasing rate of diffusion with increasing temperature is evident, as shown graphically in Fig. 2. The curves here given for copper and nickel have the same general appearance as those obtained by other workers^{6,8,9} for palladium, platinum and rubber. The specific diffusion rate of hydrogen through nickel may be calculated to be about 0.100 at 750° and about 0.012 at 500°. Thus, hydrogen diffuses through nickel at temperatures around 750° about four times as fast as it does through copper, and 80 to 100 times as fast as it does through lead and zinc at temperatures just below the melting points of the latter metals.

Summary

An apparatus has been described for studying the rate of diffusion of gases through definitely measurable areas of sheet metal at definite, uniform temperatures. The specific diffusion rate of hydrogen through several common metals, expressed in milligrams per hour per square centimeter area per millimeter thickness has been found to be:

Metal	Specific diffusion rate	°C.	Metal	Specific	diffusion rate	°C.
Aluminun	1 Not detectable ^a	555	Copper	(0.028	770
Zinc	0.0012	375	Nickel		.012	500
Lead	001	265	Nickel		.100	750
Copper	011	500				

^a Namely, less than about 0.0005.

In addition, the specific diffusion rate of hydrogen through copper and through nickel has been determined over a considerable range of temperature, and the results have been shown graphically.

Further work is in progress, by the junior author, extending this investigation over a wider range of temperature, metal-thickness and pressure variation.

THE ACTIVITIES OF ZINC, CADMIUM, TIN, LEAD AND BISMUTH IN THEIR BINARY LIQUID MIXTURES¹

By Nelson W. Taylor Received August 31, 1923

Introduction

The experimental investigations of Tammann, Mever, Ramsay, Richards and co-workers, Hulett and De Lury, Hildebrand and co-workers2 on metallic solutions have been made with the object of discovering whether the simple laws of non-metallic solutions of low polarity were applicable or whether the existence of free electrons in the metals affected their thermodynamic properties. Although the deviations from the simple concentration laws have been found to be great in many cases, it appears that all systems investigated do approach this law asymptotically in dilute solutions. The dissolved molecules are believed to be monatomic and departures from the laws of the ideal solution are to be ascribed to causes other than polymerization or dissociation of the atoms into ions and free electrons. When definite compounds are known to exist in the solid state, it is easy to explain abnormally low fugacities of the components of the solution on the basis of compound formation; but there are a number of cases where the fugacities are much greater than the simple concentration law would require. This type, also very common to organic liquid mixtures, has been suggested by Hildebrand to be due to differences in the internal pressures of the components. This theory has been very well substantiated by a large amount of vapor pressure and solubility data, and by measurements on the critical mixing temperatures of two-phase liquid systems in cases where the relative internal pressures of the components are known. In the field of metallic solutions, however, experimental work has been entirely confined to amalgams and it is of interest to extend our knowledge to other liquid mixtures. In the present investigation, by working above 400°, it has been found possible to obtain accurate values for the activities of both components of the following liquid systems, zinccadmium, zinc-tin, cadmium-tin, cadmium-lead and cadmium-bismuth, over the complete concentration range.

There are two reliable methods available for investigating the activities of the individual components of liquid metal systems: first, measurements of vapor pressures at high temperatures, as exemplified by the work of Hildebrand and Eastman on silver, gold, bismuth and thallium amalgams; and second, measurements of the electromotive force of concentration cells, in which one electrode consists of a pure metal or an alloy in which this metal has a known activity. The second method has been applied by Richards and his co-workers to a large number of solutions of electropositive metals in mercury. Except in the case of thallium amalgams, the concentration range investigated never exceeded 10% in the electromotive-force measurements but was limited by the low solubility of most of the metals in mercury at room temperature. This method has the theoretical advantage that it measures the activity directly and does not involve the assumption that the vapor obeys the simple gas laws. It has the practical advantage that a number of alloys of different concentrations can be studied simultaneously, and considerable time may be saved. Further, it is possible to work with metals of low vapor pressure. For example, at 500° the vapor pressure of zinc is about 1 mm., which would make accurate measurements somewhat difficult for alloys of low zinc content. Such alloys offer no special difficulty when the electromotiveforce method is applied. Finally, measurements may be readily made over a wide temperature range with none of the difficulties which usually attend vapor pressure work at very high or very low pressures.

In this research the electromotive-force method was used. The ordinary aqueous electrolyte used by Richards was replaced by a fused-salt mixture which contained the ion of the more electropositive component of the binary alloy under investigation. All alloys were measured against the pure electropositive metal. Thus in the system, zinc-tin, the cell may be represented as Zn | Zn++ | Zn-Sn alloy. The reaction taking place when the circuit is closed consists in a transfer of zinc from the pure state at unit activity, to the alloy where the activity of the zinc is a smaller value, a_1 . The electromotive force of such a cell is given by the equation, E = RT/nF $\ln 1/a_1$, where the symbols R, T, n and F have the usual significance. Throughout this article, the symbols a_1 and N_1 will be used to represent the activity and the mole fraction of the more electropositive component of the alloy. Thus from measurements of the electromotive force, the value of the activity may be readily calculated. It is obvious that the above reaction must be the only one taking place in the cell. The electrolyte must contain nothing which might react with either component of the alloy. It is, therefore, essential that the normal electrode potentials of the two components be sufficiently different that the more noble metal will have no effect on the ion of the other. This requirement limits our choice of metal pairs very considerably. The low-melting metals suitable

for this research have the following molal electrode potentials in aqueous solution at 25°. These values can give only a rough indication of the electrode potential of the metals against their fused salts.

Metal	Zinc	Cadmium	Thallium	Tin	Lead	Bismuth
M. p., °C	419	320	302	232	327	269
Elec. pot., volts	0.76	0.40	0.34	0.14	0.12	-0.3

Excluding systems which form two liquid phases and those in which the difference between the electrode potentials is less than 0.20 volt, we are limited to the following cases: Zn-Cd, Zn-Sn, Cd-Sn, Cd-Pb, Cd-Bi, Tl-Sn, Tl-Pb, Tl-Bi. The first five of these systems have been investigated in the present research. It may be of interest to note that some preliminary experiments showed that at 500° in a fused-salt electrolyte the cadmium ion was largely reduced by thallium, which indicates that the thallium has very probably the higher electrode potential at this temperature.

When pure molten zinc chloride or cadmium chloride is used as the electrolyte, metallic fogs are formed.³ When these fogs occur in an alloy concentration cell there results a transfer of metal through the electrolyte until all the alloys have reached the same composition. Reproducible electromotive forces are therefore not obtainable. This difficulty was overcome by using as the electrolyte a eutectic mixture of 40% potassium chloride and 60% lithium chloride which contained a little zinc chloride (or cadmium chloride). This fused-salt mixture shows no tendency to fog formation with any of the alloys investigated. It should perhaps be mentioned that the concentration of zinc or cadmium ion has no effect on the electromotive force of the type of cell used in the present research.

Purity of Materials

The potassium and lithium chlorides used in this research were found to be entirely free from heavy metals. The cadmium and zinc chlorides and potassium hydroxide contained very slight traces of iron, just sufficient to give a faint pink color with potassium thiocyanate. This corresponds to about 0.005% of ferric ion, which is entirely too small to make any appreciable change in the composition of the alloys. These salts contained some water so that there was some hydrolysis on fusion, with the liberation of hydrogen chloride which was neutralized by addition of fused potassium hydroxide.

The cadmium and bismuth had been obtained from a foreign commercial source. Those metals were used without further purification. The presence of 0.5% of impurity would not affect the electromotive force of the cells more than 0.00015 volt, which was the accuracy obtained in the actual measurements. The zinc, tin and lead had been used in a previous investigation in this Laboratory, and were of known purity.

Description of Apparatus

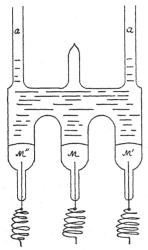

The cell used was a modification of the type used by Richards and Daniels in their study of the electromotive forces of thallium amalgams.^{2g} Since the work was all at high temperatures, Pyrex glass was used. The cell contained 6 cups, in 2 of which were

⁸ Lorentz, Z. anorg. Chem., 91, 46 (1915).

⁴ Hogness, This Journal, 43, 1621 (1921).

placed samples of the more electropositive metal while the other 4 cups contained alloys of known composition. These cups were approximately 12 mm. in internal diameter and 25 mm, in depth. Tungsten wires, sealed through the base of each cup, formed the electrodes. These were soldered with german silver to heavy copper wires which led out of the furnace and connected with the potentiometer. In the first experiments graphite electrodes were used, but this method was soon discontinued on account of the formation of metal carbides. During the course of the research there was no evidence of solution of tungsten in the molten alloys. The cell was supported in the furnace by the long glass tubes, a, Fig. 1. For suggestions in the design of all cells used in this research and for their construction the author is indebted to Mr. W. J. Cummings, glass blower of this Laboratory.

All measurements were made in a large, thick-walled electric furnace which was heated by 4 Nichrome units in parallel. The air inside was circulated by two large fans. By adjustments of current at half-hour intervals the temperature would remain at 580 ± 1.5° with a power input of 2.6 kilowatts. Four temperatures were used: 430°, 475°,

allovs

540° and 580°. The temperatures were measured by means of 2 Chromel-alumel thermocouples which had been calibrated at the melting points of tin, zinc and antimony. The melting points of these metals had been previously determined by means of a platinum-resistance thermometer whose equation was accurately known. The values obtained in the calibration of the thermocouples were plotted on large cross-section paper and smooth curves drawn through them. From these curves all temperatures were obtained by interpolation. The accuracy was about 2°.

Experimental Procedure

Small sticks of the various pure metals were prepared by melting larger pieces in a vacuum and running the molten metal into glass tubes. When the glass was broken the stick came out with a clean surface. Alloys of known compo-Fig. 1.—View of one-half sition were prepared by weighing these sticks. of the 6-cup Pyrex cell. M is The average weight of the whole alloy was 7 or a pure metal, M' and M" are 8 g. These weighed sticks of pure metal were put into the proper cups in the cell, all but two

inlet tubes were sealed off, and the cell was placed in the furnace and heated in a stream of pure hydrogen until the sticks of pure metal had melted and run together to form a more or less homogeneous alloy. In the meantime the electrolyte was prepared by fusion of the eutectic mixture of potassium and lithium chlorides with a small amount of zinc or cadmium chloride and potassium hydroxide. A stick of pure metallic zinc (or cadmium) was usually added to the electrolyte to ensure complete removal of hydrogen When the metals in the cell were melted, the hydrogen flow was stopped and immediately the clear electrolyte was poured into the cell, and care was taken that the globule of zinc (or cadmium) was left behind. Sometimes the electrolyte contained small amounts of zinc oxide or cadmium oxide. This apparently did not affect the electromotive forces obtained.

The heavy copper wires from the cell connected through mercury cups to the potentiometer. This was a commercial instrument and was used in connection with a working battery of 2 Edison accumulators. A Weston cell, giving an electromotive force of 1.01862 volts at 22° was used as standard. This cell was frequently checked against other standard cells in this Laboratory, and was found to remain constant.

Using a 6-cup cell, in which 2 cups contain the same pure metal, it is possible to make duplicate measurements of the electromotive forces of the pure metals against each of the 4 alloys. These electromotive forces may be checked further by measurements of various combinations of the alloys themselves and by suitable additions and subtractions of the values obtained. The alloys at first were not homogeneous so that the electromotive forces changed more or less rapidly at first, but after 5 or 6 hours, they became constant to 0.1 mv. and remained so during the subsequent 3 days. Temperature readings and electromotive-force readings were taken every half hour until 10 or 12 readings had been obtained and it was evident that the electromotive forces were remaining constant.

The furnace temperatures were usually changed in the following order: 470°, 540°, 470°, 430°, 540°, 580° and 470°. The advantage of returning to a previous temperature after 8 or 10 hours is that the old electromotive forces may be thus checked to see whether they have remained constant over long periods of time. Any change which might take place in the composition of the alloys is thus readily detected. In some cases the electromotive forces were found to have risen 0.2 or 0.3 mv. over a 24-hour period. This was apparently due to a very slow diffusion of oxygen through the electrolyte to the alloy surfaces. In cases where the electromotive forces had changed in this way, all subsequent measurements were corrected by the amount of the change. All final electromotive force values are averages of 10 or more readings. The duration of a complete run was ordinarily 50 to 60 hours, but there were a number of cases where leaks developed and the run was not completed. The fused electrolyte has a devitrifying action on Pyrex glass so that the cell usually became quite fragile after 2 or 3 days' heating and it was necessary to build a new cell for every run.

To illustrate the constancy of the electromotive-force values over a long period of time, the following data are quoted from the system, cadmiumlead (Run 3). The time is measured from the beginning of the run.

The experimental results on the various alloy systems will now be recorded, together with the values of $\log (a/N)$ calculated from the actual data. The significance of the quantity $\log (a/N)$ may be made clearer by considering the following relationships. In general, when 1 mole of one

component is transferred from the pure state to an alloy in which its activity is a_1 the decrease of free energy is $\Delta F = RT \ln a_1$. If the liquid

alloy obeys Raoult's law the free energy decrease is $\Delta F = RT \ln N_1$. The excess free energy of one component of an actual alloy over the value which it would have if the solution were ideal, is $\Delta F = RT \ln (a_1/N_1)$. Furthermore, since a/N is equal to unity for an ideal solution, a curve of a_1/N_1 or $\log (a_1/N_1)$ plotted against N_1 makes a very satisfactory way of representing the deviation of any solution from the ideal. The horizontal line corresponding to $\log (a/N) = 0$ represents Raoult's law. By extrapolating the $\log (a_1/N_1)$ curve to the point where N_1 is equal to zero it is easy to obtain the limiting value of a_1/N_1 , which is the so-called Henry's-law constant for this component. As a matter of fact, the curves exhibited in this article show that a_1/N_1 is never constant over any finite range of concentration, and therefore the Henry's-law constant cannot really be considered a constant at all, although in a great deal of vapor-pressure data recorded in the literature this ratio has been found "constant" within fairly narrow limits of experimental error.

The activity of the second component of these alloys has been obtained from that of the first by means of the Duhem equation, which may be expressed as follows: N_2 d log $(a_2/N_2) = -N_1$ d log (a_1/N_1) . This may be written in the integrated form $\log (a_2/N_2) = -\int_0^{N_2} N_1/N_2$ d log (a_1/N_1) .

The value of the right-hand term of this expression may be determined by first deriving an empirical equation which will give the experimental values of $\log (a_1/N_1)$ as a function of N_1 , and then carrying out the above integration. In the present research it was found simpler, however, to plot the smoothed-out values of $\log (a_1/N_1)$ at even mole fractions as abscissas against the corresponding values of N_1/N_2 as ordinates, and to determine

the area under the curve up to any desired value of N_2 . This process, although somewhat tedious, may be carried out with a fairly high degree of accuracy and rapidity. There are two choices of a standard state for the second component of the alloy. The standard state of the first component has been fixed by defining $a_1=1$ when $N_1=1$. The same choice is made in this article for the second component, namely $a_2=1$ when $N_2=1$. The other possibility is to define a_2/N_2 as equal to unity when $N_2=0$. The two standard states are related by a constant factor. For example, in cadmium-tin solutions at 483° , the value of $a_2/N_2=2.15$ when $N_2=0$. If the value of a_2/N_2 when $N_2=0$ had been defined as equal to unity, all the other values for a_2/N_2 in the other concentrations would be obtained by dividing the present values by 2.15.

The System: Cadmium-Tin

Four runs were made, two of which were successful. The following values are the actual electromotive forces obtained. Each value is the average of about 10 readings taken at half-hour periods. In this and in

The calculated values of $\log (a_1/N_1)$ obtained from these two runs have been plotted against N_1 . The average deviation of the individual values from the smooth curves is 0.006 at 433°, 0.004 at 484° and 0.002 at 546°. In determining the curve, equal weight has been given to all the experimental points, but it is possible that the values for Run 2 are somewhat low and that all the values on the curve should be slightly higher. The smoothed-out values of $\log (a_1/N_1)$ and the corresponding calculated values of $\log (a_2/N_2)$ at various mole fractions are recorded in Table III (A–D). The values of a_1 and of a_2 are also given.

Part of the data is summarized further in Fig. 2, and in Fig. 3. The results at all the temperatures are not shown in these curves but are used later in calculating heats of dilution.

The System: Cadmium-Lead

Three complete runs were made on cadmium-lead alloys. The electromotive-force values recorded are each averages of 10 or more individual readings. The average deviation of the individual points from the smooth $\log (a_1/N_1)$ curve is as follows: 0.004 at 432°; 0.002 at 480°; and 0.002 at

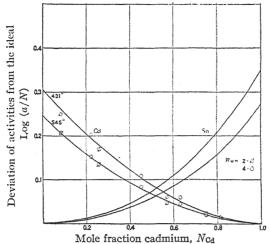

Fig. 2.—System, cadmium-tin. Deviation from the laws of the perfect solution. The horizontal line $\log (a/N) = 0$ corresponds to Raoult's law

 544° ; and 0.001 at 572° . The smoothed-out values of log (a_1/N_1) and the corresponding values for log (a_2/N_2) are recorded in Table V (A–D). Part

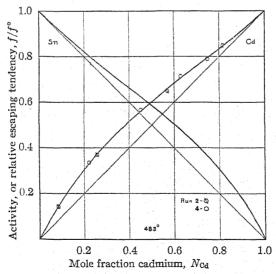

Fig. 3.—Activity curves for the system, cadmium-tin, at 483°

of the data is summarized further in Figs. 4 and 5. Comparison of these with the corresponding curves for cadmium-tin alloys shows about

The System: Cadmium-Bismuth

Satisfactory measurements were obtained in four different runs. The recorded electromotive-force values are again averages of 10 or more individual readings.

During this run (No. 4) the wire connecting with the pure cadmium electrode broke, and it was impossible to measure Cells 12, 13, etc., directly. Cells 32, 34 and 35 were, therefore, measured and the electro-

motive-force values are recorded here. The electromotive force for Cell 13 has been obtained by assuming that the $\log (a_1/N_1)$ value for Alloy 3 is correctly given by interpolation from the smooth plot of the other $\log (a_1/N_1)$ values obtained from the other runs. Thus for Cell 13, $E = RT/nF [\log (a_1/N_1) + \log N_1]$. The measured values are as follows.

Temp. °C.	Cell 32	34	35	$Log(a_1/N_1)$ for Alloy No. 3
473	-0.0222	0.0146	0.0423	-0.0470
532	0241	.0157	.0457	- .0540

Each electromotive-force value at the lower temperature represents the average of 16 actual readings. They are, therefore, quite reliable. Each of the values at 532° is an average of 7 readings. From these results the following electromotive forces are obtained by the method just described.

Temp. °C.	Cell 12	13	14	15
473	0.0042	0.0264	0.0410	0.0685
532	.0050	.0291	.0448	.0748

The corresponding calculated values for $\log (a_1/N_1)$ are

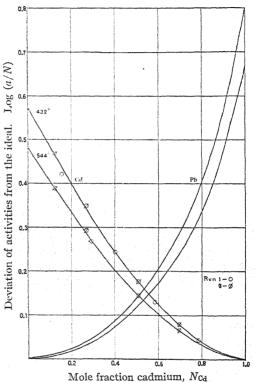

Temp				
Temp. °C.	Alloy No. 2	No. 3	No. 4	No. 5
473	0.0095	-0.047	-0.053	-0.027
532	.0034	054	061	- .039

The point corresponding to Alloy No. 5 is entirely off the $\log (a_1/N_1)$ curve, but the other points from this run fall very close to this curve with an average deviation of 0.0005 at $473\,^{\circ}$ and of 0.004 at $532\,^{\circ}$. When all the points from the 4 runs are examined the average deviation of these points from the accepted smooth curve is found to be 0.002 at $431\,^{\circ}$, 0.001 at $477\,^{\circ}$ and 0.002

at 533°. This is about the magnitude of the effect produced by an uncertainty of 0.1 mv. The activities of the components of the system cadmium-bismuth are, therefore, known with considerable accuracy.

Table VII (A–C) records the interpolated values of log (a_1/N_1) and of log (a_2/N_2) at various mole fractions of cadmium. The results are of great

interest, in that they show the remarkable behavior of cadmium-bisthe system, muth, in deviating to a greater extent from the ideal solution [where log (a_1/N_1) = 0] at high temperatures than 0] at high temperatures than tow. Cases of this kind are very rare. The system, cadmium-bismuth, is evidently very complex. It is possible that some tendency exists to form a weak compound, Cd₃Bi₂, in the liquid state. Such a factor would reduce the activities of both components and would tend 5 to annul the effect of any factor which produces abnormally large activities. When this system was investigated no compound between cadmium and bismuth had been reported in the literature from a study of freezing-point data. At the suggestion of of this Laboratory made a

a study of freezing-point data. At the suggestion of the laws of the perfect solution. The horizontal the author, Mr. H. C. Betts $\log (a/N) = 0$ corresponds to Raoult's law

series of cooling curves on cadmium-bismuth alloys of about the composition corresponding to Cd_3Bi_2 . He discovered at 161° a slight break in the freezing-point curve, which indicates the existence of a weak compound. The existence of this compound is not surprising, since freezing-point diagrams show evidence of compounds corresponding to Zn_3Sb_2 and Cd_3Sb_2 .

The results are further summarized in Figs. 6 and 7. The initially high activity of each component when present in large excess is evidence that at such concentrations the internal pressure difference is the predominating factor. As the mole fractions of the two components become more nearly

equal, their activities are abnormally reduced by formation of compounds in solution. The Duhem relation requires that when the log (a_1/N_1)

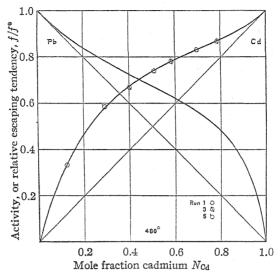

Fig. 5.—Activity curves for the system, cadmium-lead at 480°

curve shows a minimum there will be a corresponding maximum for the log (a_2/N_2) curve at the same composition. This is well brought out in Fig. 6. Similarly, when one curve shows a point of inflection the other must

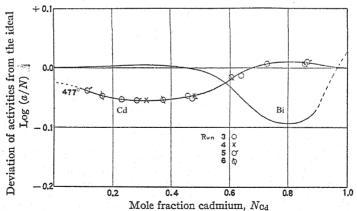

Fig. 6.—System, cadmium-bismuth. Deviation from the laws of the perfect solution. The horizontal line $\log (a/N) = 0$ corresponds to Raoult's law

also change its curvature. In Fig. 6 the log (a_2/N_2) curve (for bismuth) inflects at about $N_{\rm Cd}=0.15$. Hence, the log (a_1/N_1) curve (for cadmium) has been drawn with an inflection at the same point, although unfortu-

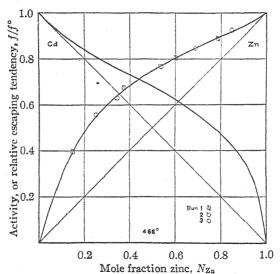

Fig. 9.—Activity curves for the system, zinc-cadmium at 466°

The System: Zinc-Tin

Three independent runs have been made on alloys of zinc with tin, and reliable results have been obtained at 431°, 466°, 539° and 570°. The data follow. Each electromotive-force value is the average of 10 or more readings.

When these $\log (a_1/N_1)$ values are plotted against N_1 the points from Run 2 are found to fall uniformly lower than the points from the other two runs. This was to be expected, since in preparing the electrolyte for Run 2 no potassium hydroxide was added to neutralize the hydrogen chloride

liberated by hydrolysis of the fused chlorides. When the electrolyte was poured into the cell a small evolution of hydrogen took place. Since the zinc in these alloys would be preferentially oxidized by the hydrogen ion in the electrolyte, its mole fraction in the alloys would be reduced, the elec-

tromotive forces obtained would be too high and the calculated values of $\log (a_1/N_1)$ would be too low. When these $\log (a_1/N_1)$ values from Run 2 are corrected by adding a constant factor of 0.010 at 466° and of 0.012

at 539° they fall very closely upon the smooth curve obtained from the data of the other two runs. The average deviation of all the experimental points from the accepted curve then becomes 0.001 at 431°, 0.001 at 466°, 0.003 at 539° and 0.000 at 570°.

The smoothed-out values of $\log (a_1/N_1)$ and the corresponding values of $\log (a_2/N_2)$ calculated by the Duhem relation are recorded in Table XI (A–D). Figs. 10 and 11 also summarize part of these data. The values from Run 2 are not shown in the plots.

The form of the $\log (a_1/N_1)$ curve for zinc in these alloys differs somewhat from that shown by the components of cadmium-tin, cadmium-lead, cadmium-zinc alloys. For these the $\log (a/N)$ curves are approximately though not exactly represented by a half-parabola, whereas for zinc in zinc-tin alloys the $\log (a_1/N_1)$ curve flattens out considerably in all alloys containing less than about 60% zinc. The limiting value of $\log (a_1/N_1)$ where $N_1=0$, is about one-half what it would be if the curve had remained parabolic over the whole range. The activity coefficient of tin, $\log (a_2/N_2)$, is also reduced in the same region, but the effect is not so apparent because the $\log (a_2/N_2)$ values are normally rather small for all alloys rich in tin. This reduction of the activities of zinc and tin in alloys rich in

tin may possibly be due to the formation of a weak compound in the liquid alloy. The freezing-point diagram shows no solid compound, but it might be mentioned that the electromotive-force method is a much more delicate means for determining activities than the average alloy freezing-point diagram now in existence.

Comparison of the Activity Curves for Various Alloys

Of the five liquid metal systems investigated, three exhibit simple type $\log (a/N)$ curves for which the activities of each component are greater than demanded by Raoult's law. These are cadmium-tin, cadmium-

lead. and cadmium-zinc. The system zinc-tin shows too high activities, but the curve is not quite so simple as in the three cases just mentioned. The system cadmium-bismuth is still more complicated. Certain amalgams also show abnormally high activities for each component. Thus the vapor pressure of mercury at 320° from amalgams of zinc, bismuth, gold, tin and lead, is abnormally high.2i,2j,2k

If the internal pressure difference between the two components of an alloy is responsible for their abnormal increase in activity, there should be some parallelism between the values of these two quantities in various alloys.

The internal-pressures of liquid zinc, cadmium, tin, lead and bismuth can be estimated⁵ from existing surface-

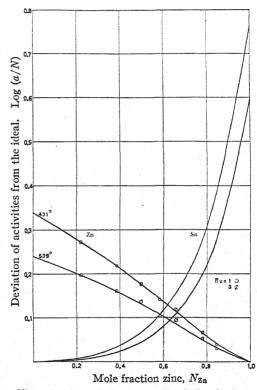

Fig. 10.—System, zinc-tin. Deviation from the laws of the perfect solution. The horizontal line $\log (a/N) = 0$ corresponds to Raoult's law

tension and density data⁴ on these metals. The values at 450° of the quantity $E_{\sigma}/V^{1/2}$ where E_{σ} represents the surface energy and V the molal volume, are as follows: zinc, 380; cadmium, 274; tin, 222; lead, 182; bismuth, 150. In Table XII values of $\Delta(E_{\sigma}/V^{1/2})$ for certain alloys are

⁵ Harkins, Proc. Nat. Acad. Sci., 5, 566 (1919).

compared with the corresponding activity coefficients of cadmium and tin from these alloys.

TABLE XII

	ACTIVIT	y Coefficie	nts in Vari	ous Alloys	i	
. **	t no		$\log(a/N)$ for C		Int. press. diff.	
Alloy	°C.	$N_{\rm Cd} = 0.0$	$N_{\mathrm{Cd}} = 0.1$	$N_{\mathrm{Cd}} = 0.2$	$\Delta(E_{\sigma}/V^{1/2})$	
Cd-Sn	483	0.28	0.228	0.185	52	
Cd-Pb	480	.55	.455	.369	92	
Cd-Zn	466	.80	.540	.373	106	
			Log(a/N) for	Sn		
		$N_{\rm Sn} = 0.0$	$N_{\rm Sn} = 0.1$	$N_{\rm Sn} = 0.2$		
Sn-Zn	466	0.72	0.459	0.274	158	
Sn-Cd	483	.33	.250	.184	52	

It will be observed that in the case of both the cadmium and the tin alloys there is a parallelism between the log (a/N) and the $\Delta(E_{\sigma}/V^{1/3})$ values. The two series are not strictly proportional, but there is enough evidence to show that a difference of internal pressure is a large factor in determining activities in liquid metal systems.

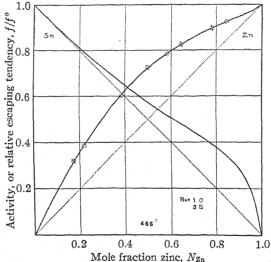

Fig. 11.—Activity curves for the system, zinc-tin at $466\,^{\circ}$

A similar comparison might be made of the escaping tendencies of zinc from zinc-cadmium and zinc-tin alloys, but the results would mean very little, since in the latter case the $\log{(a/N)}$ curve is quite irregular and is probably complicated by compound formation. The internal-pressure theory requires that solutions of zinc with lead, and zinc with bismuth show still greater positive deviations from ideal behavior than have been found in the case of cadmium-lead or zinc-cadmium solutions. The theory is

corroborated by the fact that both zinc-lead and zinc-bismuth alloys form two liquid phases. The critical mixing temperature, for these two systems are given in Landolt-Börnstein "Tabellen" as about 850° for zinc-bismuth and about 950° for zinc-lead. This temperature should be higher for zinc-bismuth if internal pressures were the only factor, but it is possible that the activities of both components are considerably reduced by compound formation just as has been found in cadmium-bismuth alloys. The fact that 2 phases are formed, however, is strong evidence in favor of the internal-pressure theory.

The Heat of Mixing

The heat of the reaction taking place in a galvanic cell may be readily calculated from measurements of the electromotive force of the cell at different temperatures. Calculations made using the electromotiveforce data obtained in the present research, give the heat absorbed during the transfer of 1 mole of pure liquid metal from the pure state to an alloy of known composition. If, for example, H_1 is the molal heat content of pure zinc, and \overline{H}_1 is the partial molal heat content of zinc in a given zinc alloy, then according to the so-called Kirchhoff equation $\overline{H}_1 - H_1 = 2.303$ - $RT^2 \frac{\mathrm{d} \log (a_1/N_1)}{\mathrm{d}T}$, where the values of log (a_1/N_1) are those given earlier in this article. This equation is applicable also to the second component of the alloy; thus $\overline{H}_2 - H_2 = 2.303~RT^2 \frac{\mathrm{d} \log{(a_2/N_2)}}{\mathrm{d} T}$. The Helmholtz equation may also be used to calculate the partial molal heat of dilution of that component with respect to which the cell is reversible. Thus, $\bar{H}_1 - H_1 =$ nF[T.(dE/dT)-E], where n is the valence of the reacting ion, and F is the Faraday constant, namely 23074 calories per volt-equivalent. The quantity $\overline{H}-H$ has been defined as the relative heat content, \overline{L} , of one component of an alloy of some definite composition.6 The absolute values of H and of \overline{H} have no interest in the present connection; it is only the heat effect accompanying the reaction which is important.

The partial molal heats of dilution of the more electropositive component of each alloy system have been obtained in the two ways—by applying the Helmholtz equation to the individual electromotive values, and then plotting these heats and interpolating at even mole fractions, and also by using the Kirchhoff relation with the $\log (a/N)$ values at these even mole fractions. The heat values obtained by these two methods have been averaged and the results are recorded below. In general the agreement between the two sets of values was just about proportional to the average deviation of the experimental $\log (a/N)$ values from the accepted smooth curves. If these points had exactly fitted the $\log (a/N)$ curves there would

⁶ Randall and Bisson, This Journal, 42, 347 (1920).

of course have been no discrepancy between the 2 sets of heat values. The Kirchhoff equation is the only one applicable to the less electropositive component of the alloy.

The accuracy of the heat values depends upon the size of the temperature interval. For example, in the neighborhood of 500°, an error of 0.0001 volt in one of the electromotive-force values produces an uncertainty of 25 calories in the heat effect when the temperature interval is 140°, about 50 cal. when the temperature interval is 70°, and about 100 cal. when this interval is only 35°. Calculations of the partial molal heats of dilution for each component of the systems cadmium-tin, cadmium-lead, cadmium-zinc and zinc-tin have been made for two or three temperature intervals in the attempt to determine (1) the relation between the heat of mixing and the deviation from the laws of the perfect solution, and (2) how the heat of dilution changes with the temperature.

The heat values are recorded in Table XIII. In the first line it will be seen that when 1 mole of pure liquid cadmium is added to a very large amount of pure liquid tin at the same temperature, the heat absorbed amounts to 1360 calories. Similarly, if 1 mole of pure liquid cadmium is added to a very large amount of a cadmium-tin alloy in which the mole fraction of cadmium $(N_{\rm Cd})$ is 0.3, only 830 calories will be absorbed. It will be noticed that certain values in the third column of Table XIII are in parentheses. These values are somewhat uncertain. All the values in this column are extrapolated from the data in the remaining columns.

Table XIII Summary of Partial Molal Heats of Dilution, $\overline{H}-H$ In Calories

		466-539	4600	3060	1990	1300	840	510	300	150	70	20	0
		431-466	(4100)	3200	2340	1560	1000	620	370.	190	70	20	0

Inspection of this table shows that in general the various sets of heat values, calculated from different temperature intervals, are concordant.

As a rule the discrepancies are not larger than the error of measurement. It must, therefore, be concluded that the change in the heat of dilution with temperature is fairly small.

The heat values given in the fourth column of Table XIII, under the heading "0.0," correspond to the heat absorbed when 1 mole of pure liquid A is added to a very large amount of pure liquid B. These particular heats of dilution bear a simple relation to the differences between the internal pressures of the two components, A and B. In order to show this relationship the values of Col. 4 are averaged and recorded in Table XIV together with the corresponding internal-pressure differences.

TABLE XIV

Internal Pressure Difference and Heat of Mixing when 1 Mole of Liquid A is Added to a Very Large Amount of Liquid B

		Heat absorbed		al press. di		_
$\boldsymbol{A}$	$\mathcal{B}$	$\overline{H}-H$ Cal.	$\Delta(E\sigma/V^{1/3})$	$\Delta(\gamma/V^{1/3})$	$(\overline{H}-H)/\Delta(E\sigma/V^{1/3})$	$(\overline{H}-H)/\Delta(\gamma/V^{1/3})$
Cd	Sn	1400 = 60	52	58	$27.0 \pm 1.2$	$24.1 \pm 1.0$
Cd	Pb	2200 = 50	92	93	$24.0 \pm 0.6$	$23.6 \pm 0.6$
Cd	Zn	$1950 \pm 200$	106	94	$18.4 \pm 1.9$	$20.8 \pm 2.1$
Sn	Cd	1800 = 50	52	58	$34.6 \pm 1.0$	$31.0 \pm 0.9$
Sn	Zn	4550 = 150	158	152	$29.0 \pm 1.0$	$30.0 \pm 1.0$

In this table two criteria have been used for estimating internal pressure. The ratios given in the last two columns are approximately constant, being especially so in the last column. The discrepancies in these ratios are no greater than the uncertainty of the internal-pressure values themselves. It may be concluded, therefore, that in liquid alloys which are not complicated by compound formation between the components, the heat of mixing is directly proportional to the internal-pressure difference. A comparison similar to that in Table XIV might be made in the case where zinc is the solute, that is, in zinc-tin and zinc-cadmium alloys. The results, however, would mean very little, since the activity curves of zinc in zinc-tin alloys are not of the simple type, and very probably the internal-pressure difference is in this case not the only factor which operates to produce departures from Raoult's law.

It has been shown that where an alloy solution is free from compounds between the components, both the deviations from Raoult's law and the partial molal heats of mixing are proportional to differences of internal pressure. It follows, therefore, that these first two quantities are closely related. For a given solute in different liquid alloy systems the partial molal heat of dilution is very nearly directly proportional to the deviation of this solute from Raoult's law.

This research was undertaken at the suggestion of Professor Joel H. Hildebrand. I wish in conclusion to express my sincere appreciation of his personal kindness and stimulating counsel throughout the investigation.

#### Summary

Accurate determinations of the activities of liquid zinc, cadmium, tin, lead and bismuth in five binary-alloy systems have been made at temperatures ranging from 400° to 600°.

With the single exception of the system, cadmium-bismuth, which gave a very complicated type of activity curve, all the alloy systems investigated showed escaping tendencies or activities greater than required by Raoult's law. In regard to departures from this ideal solution law, and also in regard to the heats of mixing, the results of this research furnish strong evidence for the validity of the internal-pressure theory as applied to liquid metal systems.

#### THE EFFECT OF PRESSURE ON OVERVOLTAGE

By S. J. Bircher and William D. Harkins Received September 6, 1923

In 1919 MacInnes and Adler¹ published a theory of overvoltage based in part upon the theory of Möller² and in part upon the then unpublished work of Goodwin and Wilson. Since then the latter have published their data,³ which indicate that overvoltage increases as the pressure is reduced, and with extreme rapidity at low pressure.

In 1914, Harkins and Adams⁴ determined the effect of pressure on the hydrogen overvoltage of mercury. They state, "Keeping the current constant, the pressure in the hydrogen cell may be raised from one atmosphere to three and reduced to twenty millimeters, without producing any significant change in the potential between the cathode and the hydrogen electrode. In such a system the potential values are never absolutely constant. They may undergo a progressive gradual change or be subject to slight eccentric variations, but such changes can in no way be correlated with changes in pressure." Newbery found that oxygen overvoltage is practically constant in the range between 1 and 100 atmospheres.⁵

It will be noted that the conclusions reached by Goodwin and Wilson, and by Harkins and Adams are quite contradictory, but it is thought that the data and discussion herein contained, which are much more closely in agreement with the latter, indicate how both conclusions have been reached.

- ⁵ Newbery, J. Chem. Soc., 105, 2419 (1914).

Both papers referred to above stress the necessity for expressing the overvoltage as a difference between the potential of the cathode and that of a reversible hydrogen electrode under the same conditions. Though this is the usual definition of overvoltage, the method of measuring such differences directly presents certain difficulties due to the non-reversibility of the hydrogen electrode at low pressures. An analysis of the experimental conditions employed by both Goodwin and Wilson, and Harkins and Adams suggested the possibility of studying certain factors individually without violation of any of the conditions inherent in the usual procedure. This analysis was undertaken after preliminary work upon the effect of pressure on the nickel cathode which appeared at first to agree with the conclusions of Goodwin and Wilson. This work was later found to be incorrect.

The effect of pressure on overvoltage as usually defined involves two distinct effects, that on the hydrogen electrode and that on the cathode potential. The practice of separating these effects when the influence of conditions other than pressure upon overvoltage is studied is quite general. It was therefore our purpose to study these effects separately and then to combine the numerical results.

In determining the effect of pressure on the hydrogen electrode potential, the hydrogen electrode and the mercurous sulfate electrode, used as a reference electrode, were in communication in the same pressure bottle. Sulfuric acid of  $0.1\,N$  concentration was used throughout and the hydrogen was prepared by the method of Cooke and Richards. Connection between the two electrodes was made by a column of sulfuric acid sufficiently long to insure the absence of mercury ions in the hydrogen electrode vessel during the time required to make the measurements.

From the data of Table I it is to be noted that the potential of the hydrogen electrode decreases as the pressure is reduced, and down to at least 100 mm, the decrease is quite close to that demanded by the Nernst formula. The accuracy of these values is well within the limits that Goodwin and Wilson, or Harkins and Adams, attained in measuring overvoltage. The greater difficulty experienced in maintaining steady potential values for the hydrogen electrode when the pressure is quite low is due to several The rate at which the hydrogen is introduced and the size of the bubbles admitted tend to produce fluctuations in pressure. Any differences in the pressure of the hydrogen before and after it enters the cell would have a similar effect, because of volume changes. The greater tendency toward ebullition at the lower pressures may cause irregularities in the pressure due to irregular bubble emission. If the capacity of the hydrogen electrode is small or if it is not sufficiently well saturated with hydrogen it may cease to function as a hydrogen electrode entirely at low pressure. The potential under such conditions becomes quite positive-

⁶ Cooke and Richards, Am. Chem. J., 10, 81 (1888).

about that of the single potential of platinum in sulfuric acid. In so far as the pressure conditions are favorable to equilibrium conditions the potential of the hydrogen electrode is a function of the partial pressure of the hydrogen.

In order to define certain terms and conditions, several factors will be discussed before dealing with the effect of pressure on the potential of the cathode.

The term reduction in pressure may be interpreted in either of two ways. It may refer to changes in the total pressure of the gases above the electrolyte irrespective of their nature or number, or to the change in the partial pressure of some one gas without a change in the total pressure of the gases in the system. The potential of the hydrogen electrode is assumed to be dependent only upon the partial pressure of the hydrogen, whether that is produced by a change in the total pressure of pure hydrogen or by varying the percentage of hydrogen in the mixture of gases present in the system. The methods used for the study of the effect of pressure on the potential of the cathode are such that both the partial pressure of the hydrogen and the total pressure in the system vary. This makes it necessary to determine the part that each of these two factors contributes to the potential changes noted. If, as in the case of the hydrogen electrode, the potential of the cathode is dependent upon the partial pressure of the hydrogen and is independent of the total pressure, and the overvoltage increases rapidly at low pressure as observed by Goodwin and Wilson, it should then be possible to increase the polarization of a cathode which exhibits a certain potential when operating in an atmosphere of pure hydrogen by replacing this gas with another gas such as nitrogen. Experience has not supported this conclusion. According to the Nernst equation the potential of the hydrogen electrode becomes more positive as the pressure is reduced, and the data of Goodwin and Wilson indicate that decreased pressure makes the cathode more negative. According to this it may be assumed that pressure need not change the cathode potential in the same direction as it affects the potential of a reversible hydrogen electrode.

The use of the hydrogen electrode as an anode in work at low pressures involves certain factors not involved in other work on overvoltage. At atmospheric pressure there is a limit to the amount of current which may be passed through a cell having a hydrogen electrode as an anode without polarizing the anode. It has already been mentioned that the hydrogen electrode itself may become less stable at low pressures. It is therefore concluded that if a hydrogen electrode is used as the anode at low pressure the possibility of polarization is much greater. This makes it advisable to use an electrode with large hydrogen capacity so that the oxygen liberated per unit area will be small. The area of the platinum base is not the only factor which determines the capacity of the electrode for the sorption of

hydrogen. The nature of the platinum black deposit is also important. The capacity of electrodes may be compared by noting the time it takes for bubbles to appear if the electrolyzing circuit in which they are serving as electrodes is reversed.

The use of hydrogen anodes of large capacities makes the time required for the establishment of the equilibrium potential after a change in pressure much longer. With the added danger of oxygen polarization when the electrode serves as an anode it is impractical to use the anode to determine the reversible hydrogen electrode potentials at low pressure. Although such hydrogen anodes are more sluggish in attaining the reversible hydrogen electrode potential, their potentials are much steadier and consequently the current is much more constant than could be obtained with anodes of other types.

The design of the cathode is important in the investigation of overvoltage, and certain requirements are worthy of discussion. The danger of polarizing the anode has led some investigators to use a small cathode. There are two errors which attend this use of very small electrodes. The first has its origin in the close relation of overvoltage to surface tension. some investigations the electrodes have been discs of metal surrounded by glass, shellac, or other supporting and insulating materials. Now it is known that with a mercury electrode the bubbles tend to form between the glass and the mercury, so it is logical to assume that with other metals also the potential may be affected by the presence of a second phase with a different surface energy. There is a second error involved and this may be greatest when a study of the effect of pressure is made. The use of a cathode so small that a bubble is large compared with the size of the cathode may introduce a condition quite foreign to that met with in ordinary large electrodes. The lead cathode used by Goodwin and Wilson⁷ had an area of 0.0033 sq. cm., which is small compared to the size of bubbles which may be liberated. This is especially true at low pressures where the volume of the gas is great.8 It is better to use a very large anode than to introduce uncertainty of conditions by the use of small cathodes.

In the present work the effect of pressure on the potential of the cathode has been studied at two current densities at least for each of the metals used by Goodwin and Wilson. The cathodes used included mercury, the metal investigated by Harkins and Adams. For reasons given in a previous paper the current densities were selected without reference to the number of bubbles being liberated per second. For each metal in Tables

⁷ Ref. 3, p. 173.

⁸ It is important to note the fact that overvoltage is peculiarly sensitive to variations in the experimental conditions, so certain properties or relations are often cited as characteristic of overvoltage even though they have been found only by the use of highly specialized conditions.

II, III and IV a description of the cathode is given together with data on current density, the cathode potential and the overvoltage. The overvoltage values were obtained by subtracting the potential of the reversible hydrogen electrode at the given pressure from the cathode potential at the same pressure.

The cathode potentials are practically constant at all pressures studied except for temporary fluctuations. These fluctuations will be discussed

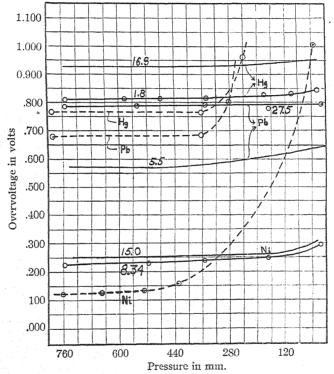

Fig. 1.—Relation of the hydrogen overvoltage to pressures of one atmosphere or less. The dotted lines represent the data of Goodwin and Wilson, the full lines, the data of the present paper. Two full lines are given for each metal; the higher line represents the higher current density. The two lines for nickel are close together, which indicates that at 20° an increase of current density is much less effective in increasing the overvoltage of nickel than in the case of the other two metals. The current densities for the respective lines are given in the figure except that the numbers for mercury give the currents instead of current densities

in considering the conclusions reached by Harkins and Adams. The overvoltage shows a slight increase paralleled by a decrease in the potential of the reference electrode. The order of magnitude of these changes in overvoltage is about 50 millivolts for a change from atmospheric pressure to a partial pressure of 11 mm. According to Goodwin and Wilson, correspond-

ing changes produce at least 850 millivolts' difference in overvoltage. For comparison, the values of Goodwin and Wilson are plotted in Fig. 1 by lines represented by dashes while the data of the present paper are represented by continuous lines.

The conclusion reached by Harkins and Adams that pressure has no effect on overvoltage, except for eccentric variations which they could not correlate with pressure, is probably due to the relatively small variations that do occur compared to the unsteadiness otherwise associated with overvoltage potentials. We have been able to correlate many such fluctuations with the changes of *total* pressure. In discussing the use of the hydrogen electrode as the anode we have indicated reasons for the non-reversibility of the hydrogen anode when used under the conditions peculiar to work on the pressure effect.

The data of the present paper show fluctuations at any one pressure which might be termed eccentric. It was often observed that as the pressure was being reduced, the cathode potential would increase and then later decrease. However, more careful observation shows that such increases are due to the rapid expansion and later escape of a bubble already on the cathode. (See Table II.) Such changes are more noticeable when only one bubble is present on the cathode, particularly in the case of mercury. Here the small bubbles which form around the edge later gather to form a large bubble at the top of the meniscus. The variation of the potential during the growth and escape of one of these bubbles is several millivolts.

The cathode potential becomes more negative as the bubble grows until it is large enough to roll upon the surface as the small bubbles unite with it.

^a A large bubble was observed to leave just *before* the reading was taken. Note the *lowering of the potential* which this caused.

When this occurs the potential decreases slightly at first and then very rapidly as the bubble escapes. The galvanometer deflections indicate the tendency for the bubble to escape several seconds before the bubble leaves the cathode. These observations as to the effect of bubble size on overvoltage do not seem at first to be in agreement with the effects of bubble size on overvoltage as observed by MacInnes and Adler. However, the conditions of the two experiments are quite different so that differences are to be expected. It is planned to extend the work connected with bubbles on mercury and discuss the subject in a later paper.

Two conditions may produce apparent increases in overvoltage of con-

siderable magnitude. There is a possibility that the reference hydrogen electrode may cease to function reversibly and may thus revert to a platinum electrode. A second possibility is that a large fraction of the cathode may become covered with hydrogen bubbles at the lower pressures. This may cause an apparent increase in overvoltage in two ways. First, this layer of hydrogen gas would introduce a resistance in the electrolyzing circuit. Second, if the bubble merely insulates part of the cathode area the overvoltage would increase because of the increased current density. Such variations would be quite apparent if the cathode area were small compared with that of one bubble.

#### Summary

- 1. The effect of pressure on the *potential* of a cathode at which hydrogen is being liberated is in general very small at pressures between 760 mm. and 11 mm. The slight changes which occur are due to bubble expansion and consequent shielding of the cathode, and to increased stirring caused by the more rapid bubble liberation at low pressure.
- 2. Overvoltage defined with reference to a reversible hydrogen electrode increases as the pressure is decreased. This increase is paralleled entirely by a decrease in potential of the hydrogen electrode. Between 760 mm. and 11 mm. the range of variation of the overvoltage is about 50 millivolts.
- 3. The data of the present paper are of interest in connection with the theory of overvoltage presented by MacInnes and Adler.1 According to them the overvoltage (E) is given by the equation,  $E = (3RT/2pr) \cdot \gamma$  in which p is the pressure in the bubbles, r their radius, and  $\gamma$  the surface tension of the liquid. They reach the conclusion that the bubble radius is practically constant with variation of pressure, so the overvoltage should vary inversely as the pressure and thus increase very rapidly as low pressures are approached. The present work indicates that the overvoltage increases with decrease of pressure only to the extent that the hydrogen electrode potential decreases, that is, as the logarithm of the pressure. On the other hand, in earlier work in this Laboratory the overvoltage of a number of inactive metals was found to have the same temperature coefficient, and to decrease 2 mv. per degree in 0.1 N sulfuric acid. seems to point to the surface tension of the liquid as an important factor in overvoltage. The above facts, taken together, seem to indicate that the theory of MacInnes and Adler is a partial rather than a complete theory of overvoltage.
- 4. Care was taken to avoid stirring of the liquid around the cathode, so the smallness of the increase of overvoltage with decrease of pressure cannot be due to the effect of stirring. The considerable lowering of overvoltage of the ordinary type produced by stirring was pointed out by Harkins and Adams⁴ in 1914.

5. The overvoltage at a mercury meniscus in dil. sulfuric acid was found to *increase* as the large bubble at the top of the meniscus becomes larger, and to *decrease* suddenly when the bubble escapes.

#### THE INDIVIDUAL THERMODYNAMIC PROPERTIES OF IONS

By J. N. Brönsted

RECEIVED SEPTEMBER 8, 1923

## The Principle of the Specific Interaction of Ions

The available information regarding the thermodynamic properties of salt solutions, as manifested through electrometric and freezing-point measurements and particularly through the measurement of the solubilities of sparingly soluble salts in salt solutions, leaves no doubt that these properties even at high dilution are largely dependent upon the nature of the solution considered. It is not a question here of the typical deviations depending upon the valence type of the various solutes, but of deviations shown by isotypic ions in dependency of their individual nature. In spite of the fact that these peculiarities have, at first sight, a rather random character, a closer examination has shown that an important simplicity prevails, which has been formulated by the writer as the principle of the specific interaction of ions.

The basis and the applicability of this principle have been elaborately presented in a previous article, where emphasis was laid upon the possibility of splitting the activity coefficient into two factors, a coefficient of interaction and a salting-out coefficient, the latter of which should be a function of the solvent only. This devision is valuable in cases where the possibility exists of determining separately the ratio of the two factors such as was shown in the previous article when salts of different valence type are used for saturating salts in solubility measurements. The calculation of these ratios requires a high degree of accuracy in the experimental determinations and but very slight deviations from the underlying principles because the equations for the calculations have such a form as to be highly sensitive towards such deviations.

The contents of the principles in question may, however, be expressed more simply without the above-mentioned division of the activity coefficient into its two factors. Let  $A_1B$  and  $A_2B$  represent two solvent salts with an anion (B) in common, and having the same equivalent concentration. Let X be an arbitrary cation and Y an arbitrary anion, present

¹ Brönsted, This Journal, 44, 877 (1922).

in small amount in the two solvents. Then our principle can be stated by the following expressions.

$$\frac{f_{\mathbf{X}(\mathbf{A}_1\mathbf{B})}}{f_{\mathbf{X}(\mathbf{A}_2\mathbf{B})}} = F(\mathbf{A}_1, \mathbf{A}_2) \tag{1}$$

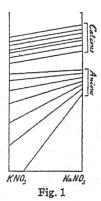

and

$$\frac{f_{Y(A_1B)}}{f_{Y(A_2B)}} = F(A_1, A_2, Y)$$
 (2)

where F represents some indeterminate function. That is to say, the ratio of the activity coefficients of the same cation in two equally strong solutions having an anion in common is a function only of the nature of the two cations of the solvents. And the ratio of the activity coefficients of the same anion in two equally strong solutions having an anion in common is a function of the nature of the anion considered and the cations of the two solvents. In neither case does the nature of the common anion of the solvents enter.

It need hardly be added that the validity of the equations will remain unaffected if throughout the above statement the terms cations and anions be interchanged.

The meaning of this law appears clear by considering the accompanying diagram (Fig. 1). The ordinates indicate  $\ln f$ , that is, the logarithms of the activity coefficient of various cations and anions of the same type. From the two vertical lines indicated by NaNO₃ (A₁B) and KNO₃ (A₂B) the values of  $\ln f$  in the corresponding solution are read, reckoned from arbitrary standard values. The  $\ln f$  values for any particular ion in the two solvents are given by the intersections of the corresponding straight lines with the two axes. In accordance

with Equation 1 the lines belonging to cations are all parallel, while in the case of anions, according to Equation 2 the slopes may be different. The shape of the curve remains unchanged when the anion of the solvent changes as, for example, in changing from potassium and sodium nitrate to potassium and sodium chloride solutions.

In the verification of the principle of specific interaction given in the previous paper the ion X in Equation 1 was changed not only in nature, its type being kept constant, but also in its general valence type. In fact, the assumption of the validity of Equation 1 under these conditions was the basis of the calculation of the ratios of interaction and salting-out effects. No experiments, however, have hitherto been available to show the applicability of Equation 1 to cases of different valence of the ions  $A_1$  and  $A_2$ . In the last part of the present paper evidence will be furnished which will show that Equation 1 is valid also for different valence of  $A_1$  and  $A_2$ , at least when X has a constant valence, and probably also when the valence of X changes.

Equations 1 and 2 and Fig. 1 furnish in reality a concise and adequate statement of what on the basis of the principle of specific interaction can be said regarding the influence of the natures of ions upon their thermodynamic properties.

It may be added that the change in the activity coefficients of a salt passing from  $A_1B$  to  $A_2B$  is given simultaneously when we remember that

$$\nu \ln f = \Sigma \nu' \ln f' \tag{3}$$

where f is the activity coefficient of the salt, f'f''. . .the activity coefficient of the ions of the salt,  $\nu'\nu''$ . . .the corresponding numbers of ions in one molecule and  $\nu = \Sigma \nu'$ .

## The Linear Variation of the Activity Coefficients

The principle of the specific interaction of ions was based on the idea that ions of the same valence must be influenced uniformly by ions of their ' own sign. The individualities in salt solutions, therefore, ought to be attributed to the interaction of ions of opposite sign, varying with the nature of these ions, and to a more general effect upon all ions present, namely the salting-out effect or solvent effect, depending merely on the salt solutions serving as solvents. A continued study of the fundamental considerations of this principle has shown, however, that several of the results obtained for its corroboration can also be obtained by use of another simple principle, which we shall introduce in the theory of the dilute salt solutions as the principle of the linear variation of the activity peculiarities. This principle may be stated as follows. In a dilute salt solution the osmotic deviations of the solutions and the activity deviations of any ion from an ideal value is, at constant composition of the dissolved salt mixture, a linear function of its total concentration and, at constant total concentration of an isotypic mixture, a linear function of its composition.

In this statement the expression "activity deviations" from an ideal value is understood to mean  $ln(f/f_i)$ , where f is the activity coefficient of the ion considered and  $f_i$  the ideal activity coefficient depending only upon the type of salt and the total concentration.

The first part of the above assumption, namely that at constant composition the osmotic and activity deviations are linear functions of the concentration, has already been advanced previously² for the case of pure salt solutions of univalent salts. The equation

$$1 - \varphi = \alpha \sqrt{c} + \beta c \tag{4}$$

was suggested to hold for solutions up to about  $0.1\,N$  concentration. In this equation  $\alpha$  is a universal constant the value of which at  $0^{\circ}$  is about 0.32 and varies but little with the temperature, while  $\beta$  accounts for the individualities. The ideal value of the activity coefficient is

$$\ln f = -3\alpha\sqrt{c} \tag{5}$$

² Brönsted, This Journal, 44, 938 (1922).

This part of the principle is, therefore, only an extension of the applicability of Equation 4 to valence types other than the uni-univalent, in which case it has already been verified. It remains to be shown that several of the results obtained previously on the basis of the principle of the specific interaction can be derived from the second part of the new principle.

For this purpose we shall introduce the thermodynamic equation³  $x \, d \ln f_{\text{Na}} + (1-x) d \ln f_{\text{K}} + d \ln f_{\text{Cl}} = 2d\varphi$  (6)

as applied to a mixture of sodium and potassium chloride solutions of constant total concentration. By introducing our assumption of a linear variation of the deviation coefficients with x

$$\frac{\mathrm{d} \ln f_{\mathrm{Na}}}{\mathrm{d} x} = a, \quad \frac{\mathrm{d} \ln f_{\mathrm{K}}}{\mathrm{d} x} = b, \quad \frac{\mathrm{d} \ln f_{\mathrm{Cl}}}{\mathrm{d} x} = c, \quad \frac{\mathrm{d} \varphi}{\mathrm{d} x} = d,$$

where a, b, c and d are constants, we obtain from Equation 6 when x = 0, the expression, b = 2d - c; and when x = 1, a = 2d - c and therefore for all values of x

$$\frac{\mathrm{d}\ln f_{\mathrm{Na}}}{\mathrm{d}x} = \frac{\mathrm{d}\ln f_{\mathrm{K}}}{\mathrm{d}x}.\tag{7}$$

in full conformity with Equation 1 and Fig. 1. By the same method as used in the previous paper³ we then derive

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = \ln \frac{f_{\text{NaCl}(\text{NaCl})}}{f_{\text{NaCl}(\text{KCl})}}$$

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = \ln \frac{f_{\text{KCl}(\text{NaCl})}}{f_{\text{KCl}(\text{KCl})}}$$
(8)

and therefore:

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = \ln \frac{f_{\text{HCl(NaCl)}}}{f_{\text{Hcl(Kcl)}}}$$
(9)

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = \frac{1}{2} \ln \frac{S_{\text{AgCl(KCl)}}}{S_{\text{AgCl(NaCl)}}}$$
 (10)

These equations, by means of which freezing points of the solvents with an ion in common are correlated to activity coefficient and solubilities of salts possessing the same common ion, are identical with the equations derived on the basis of the principle of the specific interaction of ions. Also, the solubility equation of salts in hetero-ionic solvents, namely,

$$\frac{S_{\text{AgCl(KNO3)}}}{S_{\text{AgCl(NaNO3)}}} = \frac{S_{\text{TlCl(KNO3)}}}{S_{\text{TlCl(NaNO3)}}} \tag{11}$$

is easily arrived at by using Equations 8 and 9. So far, the principle of linear variation and the principle of the specific interaction are quite equivalent. The equation⁴

$$\frac{S_{\text{AgCl}(\text{KNO3})}}{S_{\text{AgCl}(\text{NaNO3})}} = \frac{S_{\text{AgCl}(\text{KClO3})}}{S_{\text{AgCl}(\text{NaClO3})}} \tag{12}$$

and the more general.

$$\frac{f_{\text{HCl(NaNO3)}}}{f_{\text{HCl(KNO3)}}} = \frac{f_{\text{HCl(NaClO3)}}}{f_{\text{HCl(KClO3)}}} \tag{13}$$

³ Ref. 1, p. 895. The notation used in that article will be followed here.

⁴ Ref. 1, p. 883.

are, however, not derivable from the principle of the linear variation of the activity peculiarities. For their derivation is required the validity of the principle of the specific interaction, as given by

$$\frac{f_{\text{Cl}(\text{NaCl})}}{f_{\text{Cl}(\text{KCl})}} = \frac{f_{\text{Cl}(\text{NaNO}_3)}}{f_{\text{Cl}(\text{KNO}_3)}} = \frac{f_{\text{Cl}(\text{NaClO}_3)}}{f_{\text{Cl}(\text{KClO}_3)}} = \dots$$

$$\frac{f_{\text{K}(\text{KCl})}}{f_{\text{K}(\text{KNO}_3)}} = \frac{f_{\text{K}(\text{NaCl})}}{f_{\text{K}(\text{NaNO}_3)}} = \frac{f_{\text{K}(\text{HCl})}}{f_{\text{K}(\text{HNO}_3)}} = \dots$$
(14)

Since in the previous paper Equations 5-10 have already been verified, we must assume that the fundamental considerations underlying them, as given by the two principles and Equation 1, are correct.

Equation 8 combined with Equation 15,

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = \frac{1}{2} \ln \frac{f_{\text{NaCl}(\text{NaCl})}}{f_{\text{KCl}(\text{KCl})}}$$
(15)

which is identical with Equation 24 in the previous paper, yields an important correlation between the activity coefficients of two salts with a common ion, namely

$$f_{\text{NaCl}(\text{NaCl})} f_{\text{KCl}(\text{KCl})} = f^{2}_{\text{NaCl}(\text{KCl})} = f^{2}_{\text{KCl}(\text{NaCl})}$$
(16)

and

$$f_{\text{NaCl}(\text{KCl})} = f_{\text{KCl}(\text{NaCl})} \tag{17}$$

The activity coefficient of sodium chloride, present in a small amount in a solution of potassium chloride is then seen to be identical with the

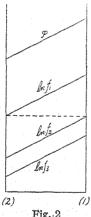

Fig. 2

activity coefficient of potassium chloride present in a small amount in a solution of sodium chloride of the same strength, this value being the geometrical mean of the activity coefficients of the two salts in their own solutions. The meaning of this is clearly illustrated by the accompanying diagram, Fig. 2, where the abscissa indicates the composition x of the mixture, and the ordinate  $\varphi$  and  $\ln f$ , and where, for instance, Salt 1 = NaCl, Salt 2 = KCl and Salt 3 = HCl. The four lines  $\varphi$ , ln f,  $ln f_2$  and  $ln f_3$  are drawn parallel, and  $ln f_{1(2)} = ln$ f2(1).

This result is reached by means of the principle of the linear variation only. This principle also leads to corresponding equations for mixtures of salts with no ion in common.

For this purpose we first use Equation 15

$$\varphi_{\rm NaCl} - \varphi_{\rm KCl} = \tfrac{1}{2} \ln \frac{f_{\rm NaCl\,(NaCl)}}{f_{\rm KCl\,(KCl)}}, \quad \varphi_{\rm KCl} - \varphi_{\rm KNO3} = \tfrac{1}{2} \ln \frac{f_{\rm KCl\,(KCl)}}{f_{\rm KNO3\,(KNO3)}}$$
 and thus

$$\varphi_{\text{NaCl}} - \varphi_{\text{KNOs}} = \frac{1}{2} \ln \frac{f_{\text{NaCl(NaCl)}}}{f_{\text{KNOs(KNOs)}}}$$
(18)

Moreover, from Equation 8,

$$\varphi_{\text{NaCl}} - \varphi_{\text{KCl}} = ln \frac{f_{\text{KCl}(\text{NaCl})}}{f_{\text{XCl}(\text{KCl})}}, \quad \varphi_{\text{KCl}} - \varphi_{\text{KNOz}} = ln \frac{f_{\text{KY}(\text{KCl})}}{f_{\text{KY}(\text{KNOz})}}$$

where X is an arbitrary cation and Y an arbitrary anion, we obtain

$$\varphi_{\text{NaCl}} - \varphi_{\text{KNO}_3} = \ln \frac{f_{\text{XCl(NaCl)}} f_{\text{KY(KCl)}}}{f_{\text{XCl(KCl)}} f_{\text{KY(KNO}_3)}}$$
(19)

Putting X = K and Y = Cl, this equation is reduced to

$$\varphi_{\text{NaCl}} - \varphi_{\text{KNO}_3} = ln \frac{f_{\text{KCl(NaCl)}}}{f_{\text{KCl(KNO}_3)}}$$
(20)

and for the reason of symmetry we also are allowed to write:

$$\varphi_{\text{NaCl}} - \varphi_{\text{KNO}_3} = ln \frac{f_{\text{NaNO}_3(\text{NaCl})}}{f_{\text{NaNO}_3(\text{KNO}_3)}}$$
(21)

By combining (18), (20) and (21) we obtain

$$\frac{f_{\text{NaCl(NaCl)}}}{f_{\text{KNO3}(\text{KNO3})}} = \frac{f^{2}_{\text{KCl(NaCl)}}}{f^{2}_{\text{KCl(KNO3)}}} = \frac{f^{2}_{\text{NaNO3}(\text{NaCl)}}}{f^{2}_{\text{NaNO3}(\text{KNO3})}}$$
(22)

or

$$\frac{f_{\rm Na(NaCl)}\,f_{\rm Cl(NaCl)}}{f_{\rm K(KNO_3)}\,f_{\rm NO_5(KNO_3)}} = \frac{f_{\rm K(NaCl)}\,f_{\rm Cl(NaCl)}\,f_{\rm Na(NaCl)}\,f_{\rm NO_3(NaCl)}}{f_{\rm K(KNO_3)}\,f_{\rm Cl(KNO_3)}\,f_{\rm Na(KNO_3)}\,f_{\rm No_5(KNO_3)}}$$

or

$$f_{\text{KNOs}(\text{NaCl})} = f_{\text{NaCl}(\text{KNOs})} \tag{23}$$

corresponding to Equation 17 for salts with a common ion.

#### Some Recent Work on Activity Coefficients

The question of the activity coefficients of salts has been discussed in a recent paper by Harned and Brumbaugh.⁵ To represent the concentration effect they use the equation

$$ln f = Ac - Bc^m (24)$$

of a form similar to that proposed by the writer, 2 namely,

$$lnf = a\sqrt{c} + bc \tag{25}$$

The two equations are, however, entirely different in that in (25) a is a universal constant, the peculiarities of the various salts being accounted for solely by the coefficient b, while in (24) A, B, and m are allowed to vary from one salt to another. As pointed out previously, an equation such as (24) does not fulfil the requirement, necessary from a theoretical point of view, of a uniform convergence of the values of  $\ln f$  for all salts, when the concentration approaches zero.

Equation 24, therefore, is to be looked upon as an empirically established expression by means of which, on account of the relatively great number of constants that may be varied independently, a rather close approximation to experimental results may be reached. The actual numerical values inserted for the constants in the equation exclude, however, its application at great dilution. Even if such an expression may be found to be helpful in some cases, it seems of more immediate importance to establish a theoretically corroborated formula for dilute solutions where

⁵ Harned and Brumbaugh, This Journal, 44, 2729 (1922).

the factors influencing the activity are still moderate in number. Equation 25 has no pretention of applicability at such high concentration, its limit being at about  $0.1\ N$  concentration for uni-univalent salts, and is not objectionable, therefore, that the minima for activity coefficients at high concentration cannot be computed with its help.

In the important question of the change of the activity coefficients in salt solutions of constant total concentration the ideas advanced by Harned are obviously in no agreement with the theory developed in this and previous articles on this subject by the writer.

It should be of some general interest to subject these ideas to a detailed discussion in order to make clear the thermodynamic or experimental requirements to be observed in developments of this kind.

In a series of solutions of the same concentration containing salts with a common ion, the activity coefficient of that ion is assumed by Harned to be constant. Accordingly, in 0.1 N solutions of sodium, potassium. hydrogen chloride, . . . and in mixtures of such chlorides the chlorine ion should possess the same activity coefficient. As replacement of potassium ion by hydrogen ion or another cation is assumed to exert no influence on the chloride ion, it is obvious on this basis that a partial replacement of the chloride ion by a nitrate ion would also have no influence, because we must assume that the greatest effect exists between ions of different sign. According to this point of view acceptance of the principle of Harned, namely, "the principle of the independent activity coefficients," would result in the assumption that all activity coefficients, at constant total concentration, depend only upon their own nature and not upon the nature of the solution containing them. This, indeed, was the conclusion drawn by Lewis and Randall.⁷ For thermodynamic reasons this conclusion, however, can be true only at ideal dilution, and in this region is included in the much simpler law that all activity coefficients are equal.

We now learn from the latest article by Harned and Brumbaugh that the Harned principle is to be interpreted somewhat differently. In equally strong solutions of sodium, potassium, hydrogen chlorides . . . and in their mixtures the chlorine ion is assumed to possess the same activity, but in their mixtures the activity coefficients of the constituent cations are assumed to vary. Furthermore, the activity coefficients of other cations introduced in small amounts are also assumed to vary from one solution to another. This assumption of Harned, although thermodynamically possible, is in peculiar contrast to the principle of the specific interaction of ions. For the theoretical reasons already stated, it is highly improbable, and furthermore it does not agree with experimental facts.

⁶ Ref. 5. The minima found by Harned and Brumbaugh and by M. Chow [This Journal, 42, 488 (1920)] in mixtures of potassium chloride and hydrochloric acid at low acid concentrations can hardly be looked upon as sufficiently established.

⁷ Lewis and Randall, ibid., 43, 1137 (1921).

Let us take, for example, solutions of sodium and potassium chlorides of equal concentration. Thallous chloride shows different solubility in these two solutions. This is possible with constant chlorine-ion activity if the thallous ion is affected differently by the sodium and the potassium ions. But if this influence is the only reason for the difference in solubility, such as the Harned theory assumes, then the same solubility ratio should be shown by all sparingly soluble thallous salt when using the corresponding sodium and potassium salt solutions as solvents. That is to say, we should expect

$$\frac{S_{\text{TICI}(\text{KCI})}}{S_{\text{TICI}(\text{NaCI})}} = \frac{S_{\text{TIX}}(\text{KX})}{S_{\text{TIX}}(\text{NaX})} = \frac{S_{\text{TIY}}(\text{KY})}{S_{\text{TIY}}(\text{NaY})} = \dots$$
 (26)

where X, Y....represent various anions. This equation, however, is clearly erroneous.

This is indicated, for instance, by the fact that oxalotetrammine-cobaltic chloride and nitrate give the following values for  $0.1\ N$  solution of the solvents.

$$\frac{s_{\text{OxCl(KCl)}}}{s_{\text{OxCl(NaCl)}}} = 1.020 \qquad \frac{s_{\text{OxNO3(KNO3)}}}{s_{\text{OxNO3(NaNO3)}}} = 1.051$$

and chloropentammine-cobaltic chloride and nitrate,

$$\frac{SP_{Cl_2(KCl)}}{SP_{Cl_2(NaCl)}} = 1.029 \qquad \frac{SP_{(NO_2)_2(KNO_2)}}{SP_{(NO_2)_2(NaNO_2)}} = 1.092$$

These values differ widely. Similar results have been found in this Laboratory in a number of cases. The principle in question is thus clearly seen to be inconsistent with experimental facts.

Moreover, if the change of the activity coefficient of a cation, when passing from a NaX solution into a KX solution of the same strength, should be independent of the nature of X while the activity of X keeps its activity coefficient unchanged, then, as can be easily shown thermodynamically, the difference in osmotic coefficients, and therefore in freezing points, of the NaX and KX solutions should be the same independently of X; or, generally, the difference in freezing points of two salt solutions with a common ion should be independent of the nature of that common ion. This result, too, is in conflict with experimental facts. For 0.1 N solutions, for instance, we have the following markedly varying differences in the molar freezing-point lowerings,  $\Delta_1 - \Delta_2$ .

Saltı	Salt	$\Delta_1 - \Delta_2$	Difference
NaNO ₃	KNO ₃	0.090 \	0.002
NaCl	KCI	.027	0.063
KC1	KNO ₃	.148	000
NaCl	NaNO ₃	.085	.063

It would be of no assistance to make the high concentrations in the above examples responsible for the failure of the principle, because this carries meaning only if the deviations from it are small, compared with the

deviations from the ideal values generally exhibited by the ions. Decrease in concentration would, therefore, mean no improvement in applicability.

The principle of independent activity coefficients, whether taken in the sense of Lewis and Randall,⁷ or as the modification proposed by Harned and Brumbaugh, is thus clearly seen to fail in accounting for the individual properties of salt solutions. It can be stated as a general and obvious conclusion that the thermodynamic and experimental evidence which has been found to be strongly confirmatory of the principle of the specific interaction of ions at the same time excludes the possibility of describing the phenomena in question by means of any theory in which "independent" activity coefficients are involved, since it is the most marked feature of this principle that the activity coefficient of an ion is, to a similar extent, a function of the nature of the ion itself and of the nature of the solution containing it.⁸

## Experimental Part. Solubility of Cobalt Ammonia Salts in Sodium Sulfate and Sodium Chloride Solutions⁹

Only uni-univalent salts were used for solvents in the earlier experimental verification of the principle of the specific interaction. As it would be of interest to try to broaden the experimental basis of the principle, experiments were performed in which solutions of sodium sulfate and chloride were used as solvents. The dissolving powers of these two solvents differ by a greater amount than in the case of two uni-univalent salt solutions and a more rigid verification is, therefore, possible with them.

As saturating substances the following three uni-univalent cobalt salts were employed: (1) oxalotetramminecobaltic-tetrathiocyanato-diammine chromiate,  $[Co(NH_3)_4Ox][Cr(NH_3)_2(CNS)_4] = OxR$ ; (2) oxalotetramminecobaltic-oxalodinitrodiammine cobaltiate,  $[Co(NH_3)_4Ox][Co(NH_3)_2(NO_2)_2Ox] = OxN$ ; (3) nitrothiocyanato-tetramminecobaltic-oxalodinitrodiammine cobaltiate,  $[Co(NH_3)_4(CNS)(NO_2)][Co(NH_3)_2(NO_2)_2Ox] = RnN$ ; of these 1 and 2 have a cation, and 2 and 3 an anion in common. Furthermore, two oxalotetrammine cobaltic salts with a bivalent anion were employed, namely, (4) oxalotetramminecobaltic persulfate,  $[Co(NH_3)_4Ox]_2S_2O_8 = Ox_2S_2O_8$ , and (5) oxalotetramminecobaltic dithionate,  $[Co(NH_3)_4Ox]_2S_2O_8 = Ox_2S_2O_8$ . All of these compounds are well-crystallizing salts, rather stable in solution and very slightly soluble in water. The solubility data for pure water as solvent at 20° are (1) OxR, 0.00139 M; (2) OxN, 0.000670 M; (3) RnN, 0.000449 M; (4) Ox₂S₂O₈, 0.000755 M; (5) Ox₂S₂O₆, 0.000201 M.

Table I gives the solubilities in the salt solutions, c being the equivalent

A glance at the solubility ratios  $\left(R_I = \frac{s_{\text{Na_2SO_4}}}{s_{\text{NaCl}}}\right)$  in the last columns of

this table shows that there is very close agreement between the values for the two salts with a common cation and a very striking deviation between the values for the two salts with a common anion. This is also shown by the accompanying graph, Fig. 3, in which the solubility ratios are plotted against the concentrations of the solvents.

These facts, however, are in full conformity with the principle of the specific interaction, as seen from the following thermodynamic equations,

$$R^{2}_{OxR} = \left[\frac{S_{OxR(NacSO4)}}{S_{OxR(NacI)}}\right]^{2} = \frac{f_{Ox(NacI)} f_{R(NacI)}}{f_{Ox(NacSO4)}}$$
(27)  

$$R^{2}_{OxN} = \left[\frac{S_{OxN(NacSO4)}}{S_{OxN(NacI)}}\right]^{2} = \frac{f_{Ox(NacI)} f_{R(NacSO4)}}{f_{Ox(NacSO4)} f_{N(NacSO4)}}$$
(28)  

$$R^{2}_{RnN} = \left[\frac{S_{RnN(NacSO4)}}{S_{RnN(NacI)}}\right]^{2} = \frac{f_{Rn(NacI)} f_{N(NacSO4)}}{f_{Rn(NacSO4)} f_{N(NacSO4)}}$$
(29)

$$R^{2}_{\text{RnN}} = \left[ \frac{s_{\text{RnN} (\text{NacSO4})}}{s_{\text{RnN} (\text{NacI})}} \right]^{2} = \frac{f_{\text{Rn} (\text{NacI})} f_{\text{N} (\text{NacSO4})}}{f_{\text{Rn} (\text{NacSO4})} f_{\text{N} (\text{NacSO4})}}$$
(29)

where  $s_{OxR(Na_8SO_4)}$  means the solubility of OxR in the Na₂SO₄ solution,  $f_{Ox(NaCl)}$  the activity coefficient of the Ox ion in the sodium chloride solution, etc. Now, dividing (27) by (28), and (28) by (29), we obtain

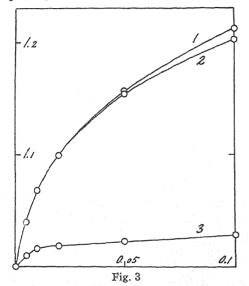

$$\left(\frac{R_{\text{OxR}}}{R_{\text{OxN}}}\right)^{2} = \frac{\frac{f_{\text{R (NaCl)}}}{f_{\text{R (NaSO4)}}}}{\frac{f_{\text{R (NaSO4)}}}{f_{\text{N (NaCl)}}}}$$

$$\left(\frac{R_{\text{OxN}}}{R_{\text{RoN}}}\right)^{2} = \frac{\frac{f_{\text{Ox(NaCl)}}}{f_{\text{N (NaSO4)}}}}{\frac{f_{\text{Ox(NaSO4)}}}{f_{\text{Rx (NaCl)}}}}$$
(31)

$$\left(\frac{R_{\text{OxN}}}{R_{\text{RnN}}}\right)^2 = \frac{f_{\text{Ox}(\text{Nac})}}{f_{\text{Ox}(\text{NacSO4})}} \frac{f_{\text{Ox}(\text{NacSO4})}}{f_{\text{Rn}(\text{NacI})}} \tag{31}$$

Since in (30) (but not in (31)) the right hand side of the equation according to our principle equals unity, the solubility ratios  $R_{\rm OxR}$  and  $R_{\rm OxN}$  but not  $R_{\rm OxN}$  and  $R_{\rm RnN}$ , accordingly, should be equal. The values in Table I furnish, therefore, a complete verification of the theory.

In an earlier communication ¹⁰ it was concluded that the solubility of uni-univalent salts was mainly governed by the equivalent concentration of the solvent, independent of its type; that is, that the shape of the solubility curves of such salts suffered no general or typical alteration when passing from one solvent to another of different type. The data now

available at low concentration show that this conclusion must be abandoned. The R-curves in the case of sodium sulfate and chloride are not rectilinear but exhibit a curvature particularly pronounced at high dilution. We infer that univalent ions are influenced by oppositely charged ions to an extent that is systematically dependent on their valence.

The values in the second and third columns of Table I confirm the earlier finding regarding the marked individualities of the activity coefficients of salts even at great dilution. It is of par-

ticular interest that the principle of the specific interaction holds in spite of very great difference in the individual values of the activity coefficients in the various solvents.

Table II

Solubilities of OxR and OxN in Solutions of Sodium Sulfate and Sodium

Chloride of High Concentrations at 20°

¹⁶ Brönsted and Petersen, This Journal, 43, 2280 (1921).

The principle of the specific interaction may be expected to hold true only in dilute solution. Some measurements were made with the two oxalotetrammine salts at higher concentrations in order to determine the limits for its validity. The results are recorded in Table II.

The deviations from the principle, as exhibited by the values of  $\frac{S_{\text{Na;SO}_4}}{S_{\text{Na;Cl}}}$  for the two salts at equal concentrations of the solvents, are perceptible in 0.1 N solution and very pronounced at higher concentrations.

The results obtained with two uni-bivalent salts in dilute solutions are given in Table III, the same notation being used as above.

Table III Solubilities of  $\rm Ox_2P$  and  $\rm Ox_2D$  in Solutions of Sodium Sulfate and Sodium Chloride at  $20\,^\circ$ 

	c	SNazSO4	SNaCl	SNa2SO4
	•	-11111004	-11401	SNaCl
	0.01	1.259	1.157	1.087
0 0 0	.02	1.409	1.250	1.126
$Ox_2S_2O_8$	.05	1.743	1.445	1.199
	.1	2.175	1.716	1.269
	.01	1.292	1.185	1.091
0-20	.02	1.465	1.294	1.133
$Ox_2S_2O_6$	.05	1.850	1.53	1.208
	.1	2.27	1.81	1.284

The values in the last column of this table show that the solubility ratios  $\left(R_{II} = \frac{s_{\text{Na;SO}_4}}{s_{\text{Na;Cl}}}\right)$  in this case also are nearly identical for the two salts at the same concentrations of the solvents, as expected from our theory.

If the ratio of the solubilities of a salt in the two solvents is taken not at the same equivalent concentration as in all the above calculations, but at the same molar concentration or at the same ionic strength¹¹ this ratio will generally approach much closer to unity. When plotting the solubilities against the ionic strength, the curves tend to coincide at very low

concentrations. The identity of the values of  $\frac{s_{\text{Na:SO}_4}}{s_{\text{NaCl}}}$  found by com-

paring two isotypic salts with a common cation does, however, appear only when the equivalent concentration is used, that is, when the cation of the solvent is present in the same concentration in the two solutions compared, a fact which is in full conformity with the ideas underlying the principle of the specific interaction of ions.

Since the measurements here mentioned involve saturating salts of different type, but with an ion in common, the salting-out ratio,  $r_u = \frac{f_{\text{(CI)}}}{f_{\text{(SO)}}}$ , can be calculated according to the theory given in the previous ¹¹ Ref. 8, p. 1140.

article.¹² Applying the formula derived there  $r_u = R_I^4/R_{II}^3$  and introducing the values of  $R_I = Rox_N$  and  $R_{II} = Rox_2 s_2 o_6$  from the tables, we find the values of  $r_u$  corresponding to the concentrations c as follows,

G	0.01	0.02	0.05	0.10
Tu	1.019	0.997	0.998	1.013

that is to say, values very near unity. As far as these experiments are concerned, the salting-out effects of the two solvents are then very nearly identical.

#### Summary

- 1. The principle of the specific interaction of ions is presented in the form of a simple equation and a diagram.
- 2. The individualities of the thermodynamic properties of salts vary linearly with their concentration when the total concentration is kept constant. On the basis of this law several of the results obtained by means of the principle of the specific interaction may be derived.
- 3. Thermodynamic and experimental evidence to prove the invalidity of the principle of the independent activity coefficients has been adduced.
- 4. Solubility measurements embracing a series of cobaltic ammonia salts in solutions of sodium sulfate and sodium chloride have been carried out. The results were found in full agreement with the principle of the specific interaction.

# DETERMINATION OF SIZE AND DISTRIBUTION OF SIZE OF PARTICLE BY CENTRIFUGAL METHODS

By The Svedberg and J. Burton Nichols Received September 14, 1923

In the determination of size and distribution of size of particle through gravity sedimentation by Odén's method¹ one is limited to relatively coarsely grained sols of about  $100~\mu\mu$  radius or larger. Since this is due to the extremely slow rate of settling, if the effect of gravity be increased sols of true colloidal size might thus be determined. To this end we have employed centrifugal force, and since direct weighing becomes impracticable here we designed a special centrifuge so constructed that the sol may be observed as it is precipitated. Then for a uniform sol, size of particle may be determined by measuring the rate of movement outward of the boundary of the particles and applying a modified form of Stokes' law.

¹² Ref. 1, p. 885.

¹ Odén, Bull. Geol. Inst. Upsala, 16, 15 (1918).

With the centrifuge the acceleration of the particle is no longer constant as in the case of gravity sedimentation but varies with the distance from the center.

Let a be the distance from the axis of rotation to the meniscus of the sol in the centrifuge tube. Then let x be the distance the boundary of the particles has moved in a given time t. Now consider the forces acting on a particle at the point x. The frictional force which tends to cause it to resist movement is  $6\pi\eta r(\mathrm{d}x/\mathrm{d}t)$  where  $\eta$  is the viscosity of the liquid, r the radius of the particle considered to be a sphere, and  $\mathrm{d}x/\mathrm{d}t$  its velocity. But the centrifugal force applied to cause movement is  $4/3\pi r^3(d_p-d_l)-w^2(x+a)$ ,  $(d_p-d_l)$  being the difference in density between the particles and dispersion medium, w the angular velocity, and (x+a) the distance from the axis of rotation to the particle.

Equating and rearranging for integration

$$\int_{0}^{t} r^{2} dt = \int_{0}^{x} \frac{9\eta}{2 (d_{x} - d_{l}) \quad w^{2}} \frac{dx}{x + a}$$

$$r^{2} t = \frac{9\eta}{2 (d_{y} - d_{l}) \quad w^{2}} ln \left(\frac{x + a}{a}\right)$$

$$r = \sqrt{\frac{9\eta ln \left(\frac{x + a}{a}\right)}{2 (d_{y} - d_{l}) \quad w^{2}t}}$$
(1)

Therefore, by measuring the distance x which the boundary of the sol has moved out in a time t, and obtaining the speed of the centrifuge it is possible to determine r.

Fig. 1 shows the centrifuge devised. The rotor A is directly connected at B to a Dumore special 20,000 r.p.m. motor C suspended in the heavy metal casing D and supported by a pivot bearing E. The machine is mounted on a large wooden base F, laminated to prevent warping, and several thicknesses of linoleum are glued on the top and bottom to absorb vibration.

The rotor is enclosed in a square metal box G for the purpose of protecting the tube from air currents and resulting temperature differences. Air may be blown through the box also in order to obtain constant temperature. The top is made removable so that the rotor may be adjusted when necessary.

The rotor consists of the central head H, horizontally cored I, to which are screwed the two arms J, also cored to correspond to the core of the head. These arms are closed at the outer end by screw caps K to provide a means for changing the tubes L contained. In order to obtain vertical or horizontal illumination of the tubes, the arms are slotted M, top and bottom and on both sides.

The tubes used L, one for each arm, are made of a good resistance glass tubing such as Pyrex or Jena, sealed off smoothly at the outer end and closed at the inner end by paraffined corks. To prevent too much strain on the rounded portion a plastic substance is filled in the space between the tube and the cap K.

A thin metal disk N, of slightly greater diameter than the length of the rotor, attached to the head just below the arms, is slotted at O directly under the vertical slots in the arms and is fixed in position so that no relative motion of arms and disc will take place. This slotted disk therefore allows light to travel up through the box only when an arm is directly over the narrow beam of light employed for illumination.

Underneath the box is mounted a narrow plane mirror P for directing a uniform beam of light vertically through a slot Q in the bottom of the box, of the same length as the slots in the arms, so that every time an arm passes over this slot a beam of light

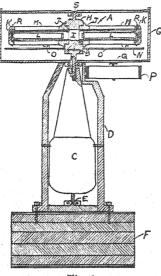

Fig. 1

travels up through the slots in the arm and through a corresponding slot in the top of the box, where the image of the contents of the tube may be observed or photographed. There is also a slot in the side of the box at such a height that light reflected from the contents of the tubes also may be viewed or photographed.

The most difficult problem to solve was to provide a good means of balancing the rotor. This is essential, for when it is not in exact balance the vibrations tend to mix the colloid and vitiate the effect of the force applied. Several different methods were employed but none was sensitive enough. However, the desired sensitivity was finally obtained by inserting a hardened steel peg on each side of the head, in order to furnish a means of support for the rotor on knife edges. These rods are so situated that the center of gravity of the rotor lies

just below the point of support, such arrangement giving maximum sensitivity. Then the end of each arm was threaded and adjustable rings R

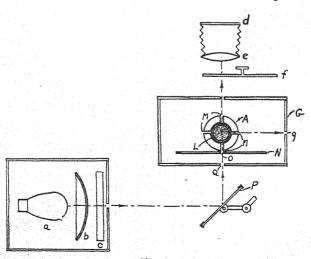

Fig. 2

gave us the means for varying the movement of the arms so that they would come to rest in a horizontal position.

Fig. 2 gives a diagrammatic representation of the apparatus and the path of the beam of light up through the sol in the centrifuge tube to the photographic plate. In this case the section of the centrifuge box is at right angles to the view shown in Fig. 1.

The source of light is a concentrated filament electric light bulb a;b is a lens of white glass to make the light beam of uniform color and intensity; c is a water cell for cooling the beam. This system is entirely enclosed in a large, asbestos-lined box to shut out stray light from the camera lens. The light then travels through a slot in the side of the

box to the narrow plane mirror P mentioned before, which reflects it up into the centrifuge box through the slot Q. Now if the arm is directly over this slot the beam of light can continue up through the slot O in the disc screen and through the slots M in the arms and out at the top slot in the box where the image of the illuminated tube containing the sol is thrown on the photographic plate d, by the large lens e; f is a sector wheel rotated at a constant rate by a small motor so as to give a known length of time of exposure to the plate.

If it is desired to photograph the reflected light from the colloid rather than the transmitted light, the camera arrangement may be changed to a horizontal position in front of the slot g. In this arrangement another light system of equal intensity to that shown is introduced so that both the bottom and the top side of the tube can be equally lighted.

Speed regulation is provided for by inserting a variable resistance in the field circuit of the motor. In this way any desired speed may be obtained. Speed of the machine is determined by inserting a speed counter or indicating tachometer at S, the top of the axis of rotation (Fig. 1).

#### Uniform Sols

The first material studied was two gold hydrosols prepared by means of Zsigmondy's nuclear method.

Equal amounts of one of the sols were sealed in centrifuge tubes and placed in the rotor of the machine. The centrifuge was started, the resistance adjusted to give the desired speed and the time of starting noted when the centrifuge had come up to speed. After a certain length of time

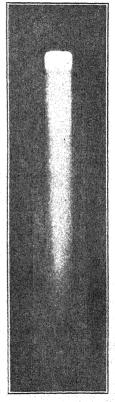

Fig. 3

the distance the boundary had moved was measured either directly by means of a centimeter scale on a glass slide or else by photographing the tube and measuring the distance from the meniscus of the sol to the boundary of the particles. The latter procedure is necessary when the boundary is not sharp. In order to get the correct point the gradual increase in density of the plate in this region was measured with a König Martin photometer and the point of medium density was considered to be the edge of the boundary; then by taking another photograph later and determining

the point on the picture corresponding to the same density the true distance moved in the given time interval could be determined.

Fig. 3 indicates the appearance of the photograph obtained. The particular photograph shown is of gold sol No. 2 at the end of 30 minutes of centrifuging.

In order to verify the values obtained from the runs with the centrifuge, the sols were determined directly by means of the ultramicroscope.

Table I
Data on Gold Hydrosol Number 1

$$r = \sqrt{\frac{9\eta \ln \frac{x+a}{a}}{2(d_p - d_1) \quad w^2 t}}$$

where a= distance from axis of rotation to meniscus of sol, 2.7 cm.; t= time of centrifuging in minutes; x= distance sedimented in cm.; r= radius in  $\mu\mu$ ;  $\eta=$  viscosity, 0.01; w= angular velocity,  $60\pi$ ;  $d_p-d_l=$  difference in density, 18.32.

Min.	Z Cm.	γ μμ	r (from ultramicroscope determination) μμ
10	0.15	24.1	
20	.28	21.1	
			21.8
30	.42	20.9	

TABLE II

Data on Gold Hydrosol Number 2  $a=2.0~{\rm cm}; \eta=0.01; d_p-d_l=18.32; w=58\pi$ 

t Min.	x Cm.	γ μμ	r (from ultramicroscope determination) μμ
15	0.3	34.0	
30	.7	35.1	
			33.5
47	.9	32.6	

In each case, considering the last value obtained with the centrifuge as the best, the results by the two methods are seen to be in very close agreement.

A sample of colloidal barium sulfate was next studied. This was made by the interaction of  $0.1\ N$  barium thiocyanate with  $0.1\ N$  ammonium sulfate, using potassium citrate as a protective agent.

Table III Barium Sulfate

 $a = 2.4 \text{ cm.}; \eta = 0.01; w = 31\pi; d_p - d_l = 3.4$ r (from ultramicroscope 12 determination) Min.  $\mu\mu$  $\mu\mu$ μμ 60 0.3 1.4 67.7142.2105 .7 5.575.3154.5 93.3 135 6.6 74.0151.0

With the barium sulfate used a very sharp boundary was obtained representing the larger size of particle, probably indicating a steep maximum at this point, and a fainter boundary representing the minimum size of particle present. As might be expected with two such very differently sized particles, the ultramicroscopic determination representing the average size of particle gives us very little information here. In addition, the barium sulfate particles scatter very little light, so the counts are difficult to make with the ultramicroscope.

The next material studied was a sample of Putnam clay prepared by Professor Bradfield of the University of Missouri. This contained a fairly narrow range of size of particle, since it represented that fraction obtained on passing the clay through a Sharples centrifuge at a speed of 30,000 r.p.m., collecting a 3-minute fraction and then passing this fraction through again and collecting the particles thrown out in three minutes.

The following results were obtained.

TABLE IV CLAY  $a = 2.5 \text{ cm.}; \eta = 0.01; w = 58\pi; d_p - d_l = 1.6$ r (from ultramicroscope determination) Min.  $\mu\mu$ 60 0.2 43.3 90 .3 42.149.4 135 41.7 .45 345 1.15 39.4

Since a slight error in measurement of the larger distance does not introduce so great an error in the results, the lower value of r obtained in the centrifuge run probably represents the minimum size of particle present. In the ultramicroscopic determination the particles were difficult to distinguish, as similar to the barium sulfate, they scatter very little light.

A sol of arsenious sulfide prepared by passing hydrogen sulfide into a solution of arsenic trioxide was also studied. As in the case of the sol of barium sulfate a double boundary appeared, the outer one being very sharp, while the inner was rather faint and indistinct.

TABLE V ARSENIC TRISULFIDE SOL  $a = 2.7 \text{ cm.}; \eta = 0.01; w = 58\pi; d_p - d_l = 2.46$ r (from ultramicroscope determination) 71 Čm. Cm. Min. μμ μμ LLIL 62.3 75.50.2 0.3 17 74.030 .4 .55 65.275.5.8 63.9 73.7.6

It should be noted that with non-spherical particles such as those of barium sulfate, arsenious sulfide, and clay the values of r determined do not represent the actual radius but the equivalent radius of a spherical particle of the material that would sediment at the same rate as the actual particle.

#### Non-Uniform Sols

Since most colloidal material contains a wide range of sizes of particles, the method just described for observing the movement of the boundary can give us complete information on only a few substances or at most the smallest size of particles contained in a non-uniform sol.

Therefore the next problem is to work out the method for determining the relative amounts present of each size of particle in a sol. One of  $us^2$  has already developed the theory of the method, using an approximate formula for r. The following is more exact.

In a thin layer dx of a sedimenting sol the change in concentration dc from the section at x to the section x + dx is due to particle with radius r to r + dr, the values of r being determined from the modified form of Stokes' law, Equation 1. By obtaining the change in c with x, that is dc/dx, we may determine the distribution function  $\frac{dc}{dr} = \frac{dc}{dx} \cdot \frac{dx}{dr}$ . In order to measure dx/dr let us rearrange Equation 1 to the form

$$\ln \frac{x+a}{a} = \frac{2 (d_p - d_l) \quad w^2 t \, r^2}{9\eta}$$
Let  $B = \sqrt{\frac{9\eta}{2(d_p - d_l) \quad w^2 t}}$ 

Substituting and differentiating,

$$\frac{\mathrm{d}x}{x+a} = \frac{2r\,\mathrm{d}\,r}{B^2}$$

Substituting the value of r from Equation 1 and rearranging,

$$\frac{\mathrm{d}x}{\mathrm{d}r} = \frac{2(x+a)\sqrt{\ln\frac{x+a}{a}}}{B}$$

a being again the distance from the axis of rotation to the point x = 0. This then gives

$$\frac{\mathrm{d}c}{\mathrm{d}r} = \frac{2(x+a)\sqrt{\ln\frac{x+a}{a}}}{B}\frac{\mathrm{d}c}{\mathrm{d}x} \tag{2}$$

The following procedure is necessary in order to obtain the variation in concentration with distance x in the centrifuge tubes. First, a picture is taken of the contents of the centrifuge tube when the rotor has just come up to speed and practically no sedimentation has taken place. Then a photograph is taken on the same plate after a given length of time of running and a third photograph is taken of a wedge cell of the material. All

² Svedberg and Rinde, This Journal, 45, 943 (1923).

three pictures must be given the same intensity of illumination and length of exposure.

Then by comparing the second and the third strips in a photometer, we obtain the density on the wedge cell strip corresponding to the density of the sol representing its original concentration. Beer's law may then be used to determine the concentration at each layer of the wedge cell and the values obtained put in the form of a scale parallel to the photograph strip of the wedge cell. The density of this strip is next determined throughout the whole height which gives us concentration in terms of density. However, if the material under observation contains a wide range of sizes of particles, the variation of the light absorption constant with radius must be considered, as already pointed out by one of us.²

Finally, the density of each layer of the sedimenting sol may be obtained from the photograph taken of the contents of the tube after the centrifuge had been running for some time, and when what each density represents in terms of concentration is known, the change in concentration with distance, dc/dx, may be determined for the material. Now the distribution curve may be plotted using as coördinates dc/dr and r.

Investigations on non-uniform colloids are being undertaken and will form the subject of a later paper.

# Summary

- 1. Stokes' law has been modified to give an exact formula for determining the radius of a particle sedimenting under centrifugal force.
- 2. A special type of centrifuge has been described which permits a sol to be observed or photographed while it is being precipitated.
- 3. This method depends on the projection of a uniform beam of light up through the tube containing the material each time the tube passes over a certain point. The rate of movement of the particles in the tube may then be observed.
- 4. To illustrate the method for a fairly uniformly sized colloid, results for two different gold sols, clay, barium sulfate, and arsenious sulfide have been given.
- 5. Another method has been discussed for determining the distribution of size of particles, depending on the variation of concentration with distance from the axis of rotation in a disperse system subjected to centrifugal force.

# THE AMMONIA EQUILIBRIUM

By A. T. Larson and R. L. Dodge¹

Received September 19, 1923

The first determination of the ammonia equilibrium was made by Haber and van Oordt² in 1905. In this investigation the reaction was studied at 1000° and 1 atmosphere pressure. In 1907 Haber and Le Rossignol³ published results of experiments which they had made at 1 atmosphere pressure and at temperatures ranging from 700° to 1000°. About this same time papers by Nernst⁴ and Jost⁵ appeared in which approximately this same temperature range was covered, but the pressure range was extended to 72 atmospheres. The following year Haber and Le Rossignol⁶ studied the ammonia equilibrium at 30 atmospheres, covering a temperature range essentially the same as that of their earlier report. The most recent work on the ammonia equilibrium appeared in 1914-1915 when Haber⁷ published a series of papers in which he gave the results of a redetermination of the equilibrium at 30 atmospheres. In the latter experiments an attempt was made to reach temperatures as low as 450° but without success, 561° apparently being the lowest temperature at which equilibrium could be established.

Using results obtained at a pressure of 30 atmospheres and temperatures ranging from 974° to 561° Haber computed the probable equilibrium values for the pressure range of 1 to 200 atmospheres and temperatures as low as 200°. These computations were based on the van't Hoff isochore, the integration of which required a knowledge of the variation with temperature of the heat of formation of ammonia from its elements. This heat of formation Haber determined experimentally.

In computing the equilibrium values for the ammonia reaction, Haber recognized the danger of applying his formula to a wide range of pressures. For the lower pressures it was felt that the effect of the deviations of the compressed gases from the perfect gas law would be negligible. At relatively high temperatures (915°) Jost⁵ has shown this to be the case.

Just what the effect would be at lower temperatures, say below 500° was, however, not known. Since the ammonia equilibrium had not been determined over a wide range of pressures, and particularly at the low temperatures now possible, it has been considered worth while to make such an investigation. The equilibrium results which have been obtained at 10, 30, 50 and 100 atmospheres' pressure are given in this paper.

# Experimental Part

The experimental procedure of this investigation was essentially as follows. A mixture of nitrogen and hydrogen (1:3) at 100 atmospheres was purified and then passed through a catalyst bomb in which any desired percentage of the gas could be converted into ammonia. If an ammonia-free gas was desired, the catalyst bomb was by-passed. When pressures lower than that of the purification train (100 atmospheres) were being investigated, an automatic reducing valve served to effect the reduction of the pressure to the desired value.

The gas now passed through a coiled iron pipe containing the catalyst. The catalyst was prepared by reducing iron oxide containing potassium oxide and aluminum oxide as promoters. (A detailed description of this type of catalyst will be published in a later paper.) A needle valve placed at the exit end of the coiled iron pipe was employed in regulating the flow of gas through the apparatus. This valve was provided with an electric heater which prevented condensation of ammonia at this point. After leaving this valve the gas pressure was reduced to atmospheric and the gas was then passed through a friction tube flowmeter. The equilibrium was approached from both sides, in every case the space velocity being progressively decreased until further reduction in flow produced no change in ammonia conversion.

# Preparation and Storage of Gas

The nitrogen-hydrogen mixture was prepared by burning electrolytic hydrogen and air in such proportions that the resulting gas mixture contained approximately 75% by volume of hydrogen. The remaining 25% was essentially a mixture of nitrogen and argon, the latter forming about 0.3% by volume of the total mixture. The flow of the hydrogen and the air was automatically controlled so that a gas of uniform composition was practically insured. The freshly prepared gas mixture was led into a (14 cu. meter) water-sealed gas holder, from which samples were withdrawn and analyzed by the explosion method. After the gas had been analyzed it was compressed into a storage system (200 atmospheres) which held about 113 cu. meters of gas (N.T.P.).

Analyses covering a period of 117 days gave as the average composition of the gas, 76.2% of hydrogen and 23.8% of nitrogen plus inert gas. The maximum deviation for the hydrogen was 2.2%. The volume of gas in

the high-pressure storage was about eight times the daily production, so that daily variations in the composition of the freshly prepared gas mixture were largely smoothed out. The average of the daily analyses represented with sufficient accuracy (see discussion of errors) the composition of the gas employed in these equilibrium experiments.

#### Gas Purification

Purification of the gas was accomplished by first bringing it into contact with copper at 300–400°. Here the oxygen was removed by conversion to water. The gas was then passed over a nickel catalyst maintained at 250–300°, where carbon monoxide combined with hydrogen to form methane and water. The gas was then passed through a water-cooled condenser, a tower containing soda-lime, two towers filled with porous granular alumina and finally a single tower containing fused potassium hydroxide.8

The purity of the gas was tested at regular intervals by slowly passing about 15 liters through a glass coil immersed in liquid air. No trace of condensable impurities was ever observed. An additional check on the gas purity was obtained by operating continuously a pilot catalyst whose efficiency would soon drop if a catalyst poison appeared in the gas.

#### Pressure Control

The pure gas under 100 atmospheres' pressures was reduced to any desired pressure by means of an automatic reducing valve. A pilot gage was placed in the line and served to indicate fluctuations in pressure, while the actual pressure was measured by means of an oil float (deadweight) gage, which had been checked against a similar gage calibrated by the Bureau of Standards. By means of this arrangement the desired pressures could be accurately maintained to within  $\pm 0.034$  atmosphere.

# Temperature Control

The catalyst was placed in an iron tube (length, 493 cm.; o. d., 1.72 cm.; i. d., 0.95 cm.) wound in an open coil. This coil was placed in a thermostat filled with fused sodium nitrate-potassium nitrate (1-1), the essential details of which are indicated in Fig. 1. The thermostat was made from a section of iron pipe (21 cm. in diameter and 46 cm. in length) with a welded-on bottom. Nichrome ribbon was wound on the outside of this pipe and served to maintain the fused salt mixture at approximately the desired temperature. The close regulation of the temperature was accomplished by means of a second heater (not shown in Fig. 1), immersed in the salt bath. The flow of current through this heater was controlled by means of a platinum resistance thermometer placed in the bath and

⁸ Tour, Chem. Met. Eng., 26, 588 (1922).

^o Larson and Karrer, J. Ind. Eng. Chem., 14, 1012 (1922).

connected to a Wheatstone bridge and contact galvanometer. With this arrangement the temperature fluctuations did not exceed  $\pm 0.25^{\circ}$ .

Alumel-chromel thermocouples were placed at different levels in the thermostat, the locations of two of them being indicated in Fig. 1. These couples were frequently checked either at the boiling point of sulfur¹⁰ or by direct comparison with a platinum-platinumrhodium couple calibrated by the Bureau of Standards. The bath was stirred at such a

rate that a further increase did not have any effect on the temperature uniformity.

# Analysis of Gas Sample

The ammonia content of the gas was determined by passing the gas through an absorber and collecting the nitrogen-hydrogen residue in a compensating buret. ¹¹ Samples of gas were analyzed under each condition of temperature, pressure and gas flow until three or more consecutive samples taken at intervals of from 5 to 15 minutes showed deviations of less than 1% of their

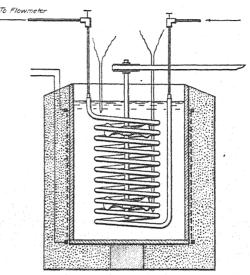

Fig. 1.—Fused salt bath

value. The average of these last samples was taken as the value for the ammonia content of the equilibrium gas mixture.

The ammonia was determined in two ways, both of which gave concordant results. In one of these methods the ammonia was absorbed in 4% boric acid solution containing either methyl orange or bromophenol blue (tetrabromo-phenolsulfonephthalein) as indicator, the ammonia being titrated with  $0.1\ N$  sulfuric acid. In the other method the ammonia was absorbed in  $0.1\ N$  sulfuric acid with sodium alizarin-sulfonate as indicator, the quantity of acid being slightly less than that required for neutralization of all the ammonia, and the excess of ammonia titrated with additional  $0.1\ N$  sulfuric acid. The sulfuric acid absorbent with sodium alizarin-sulfonate as indicator was generally used because of the particularly sharp end-point. Less than  $0.05\ cc.$  of  $0.1\ N$  sulfuric acid gave a decided color change. Its disadvantage lies in the necessity of knowing in advance approximately the amount of ammonia in the sample in order to

¹⁰ See U. S. Bur. Standards, Bull., 170 (1921).

¹¹ Tour, Chem. Met. Eng., 23, 1104 (1920).

determine approximately the correct amount of acid required for the sample. The efficiency of the absorption was tested by using two absorption bottles in series but no titrable amounts of ammonia were ever found in the second bottle.

#### Gas Flow

The rate of flow of gas passing through the catalyst coil was measured by dropping the pressure of the gas to atmospheric and passing it through a friction tube flowmeter. The flow was progressively decreased until the ammonia content of the gas leaving the catalyst coil became constant. When this occurred it was assumed that equilibrium had been reached.

With the most active catalyst available, equilibrium is not reached, particularly at the higher pressures, when the space velocity is in excess of

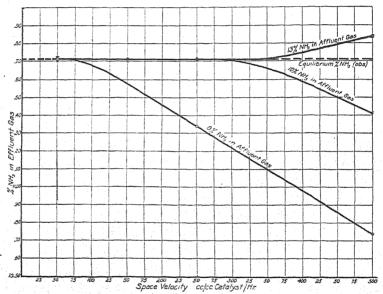

Fig. 2.—Pressure, 50 atm. (abs.) Temperature, 425°. Equilibrium, % NH3 (obs.) 11.71

5000, and the temperature is lower than 450°. For example, at 50 atmospheres' pressure and 350° equilibrium was not reached until the space velocity was lowered to 10. With 1 cc. of catalyst for example, this would give only 0.167 cc. of gas per minute, a flow which is difficult to regulate closely. Furthermore, at such a low rate of flow analyzable samples of gas cannot be withdrawn in a reasonable length of time. Under the conditions just specified, it would require 10 hours to remove a 100cc. sample. It was necessary, therefore, to use a relatively large volume of catalyst. Accordingly, about 0.5 liter of catalyst was used (484 cc.); this permitted a gas flow which was easily controllable even at the lowest space velocities

employed, and allowed the rapid withdrawal of a sample sufficiently large for analysis.

In order that the experiment might not consume too much time the gas mixture was brought very nearly to the equilibrium condition before it entered the catalyst coil. With this assistance equilibrium was of course more readily attained. Fig. 2 shows the consequences of adding ammonia to the gas when the operating conditions permitted equilibrium to be reached readily on an ammonia-free gas. In this particular case not enough observations were made to determine the shape of the curve; but for our purpose these intermediate points were unnecessary. (The results of other investigations indicate that the space-velocity curves always approach equilibrium in this manner.)

#### Discussion of Errors

The accuracy of this determination depends on the validity of four assumptions and on the accuracy of five measured values. The assumptions are: (1) that equilibrium is actually attained; (2) that the equilibrium is attained at the measured pressure; (3) that the equilibrium is attained at the point at which the temperature is measured; and (4) that no change in the composition of the gas mixture occurs while the gases are passing from this point to the analytical apparatus.

- 1. In all cases, concordant results were obtained by approaching the equilibrium from both sides, a proof that equilibrium had actually been attained.
- 2. The non-existence of a pressure gradient of more than 0.068 atmospheres throughout the reaction coil was proved by measuring the pressure simultaneously at both ends under the limiting conditions of the investigation (that is, between 10 atmospheres' and 100 atmospheres' pressure and with flows ranging from 7 cc. per minute to 7 liters per minute).
- 3. The temperature was measured in a constant-temperature zone which surrounded approximately the top half of the catalyst coil. Although the temperature of this portion of the catalyst bath was uniform, there might still be an appreciable temperature gradient within the catalyst. In fact, for reactions involving the formation or decomposition of ammonia where large quantities of heat are liberated or absorbed a uniform temperature throughout the entire mass of the catalyst can be only approximated experimentally. By using a tube of relatively small diameter, the difference in temperature between the catalyst and the bath was probably not very great, even in that region where the reaction was most rapid. An inspection of the curves in Fig. 2 shows that when operating on ammonia-free gas, equilibrium was not attained until the flow of gas was decreased to a space velocity of 50. But at a space velocity of 500

we note that the reaction is approximately 90% completed. In other words, while operating at a space velocity low enough to give equilibrium (50 s. v.) 90% of the equilibrium amount of ammonia is formed in the first tenth of the catalyst. Since the catalyst filled the coil completely and the gases entered at the bottom there is no doubt that the equilibrium attained in the catalyst coil corresponds to the temperature of the bath surrounding the upper half of the catalyst coil.

4. In order to comply with the requirements of the fourth assumption a 1.6 mm. copper tube fitted with a steel adapter was pushed down to the catalyst. The copper tube was silver-soldered to the adapter and the adapter was welded to the iron pipe. (See Fig. 3.) In practice, the surface of the fused-salt bath was kept just below this soldered connection.

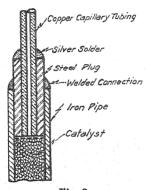

Fig. 3

In order to prevent particles of catalytic material being carried into the copper tube, a fine platinum gauze was placed between the catalyst and the copper tube. By passing the gas at a comparatively high linear velocity through a tube which has no catalytic action at these low temperatures, it is believed that there was no change in composition of the gas after it left the catalyst.

The five measured values on which the accuracy of the determination depends are (1) the composition of the gas mixture used, (2) the pressure, (3) the measurement of the residual

gas volume, (4) the titration of the ammonia absorbed from the equilibrium mixture and (5) the temperature.

- 1. In calculating the results the average composition of the gas mixture taken was 76.2% of hydrogen, 23.5% of nitrogen, 0.3% of argon. Since a 10% variation in the 3:1 hydrogen-nitrogen ratio produces an error of only 0.2% in the equilibrium constant and less than 1% in the percentage of ammonia at equilibrium, no appreciable error is introduced in employing this average value.
- 2. The pressure in the reaction coil was measured with an accuracy of 0.034 atmosphere. An error of 0.068 atmosphere at 10 atmospheres would cause only 0.7% error in the equilibrium constant; at the higher pressures the error would, of course, be correspondingly less.
- 3. The residual gas volume was measured with an accuracy of 0.2% which corresponds to an equal error in the calculation of the percentage of ammonia at equilibrium and an approximately equal error in the equilibrium constant.
- 4. The error in the standard acid solution was not greater than 0.5%. An error of 0.05 cc. in the titration of samples taken at 10 atmospheres

and  $500^{\circ}$  would cause a 1% error in the percentage of ammonia (at the lower temperatures and higher pressures the error would be correspondingly less). All the errors of analysis acting in the same direction would give an error of 1.7% in the percentage of ammonia. This corresponds to an approximately equal error in the equilibrium constant.

Table I
Observed Percentage of Ammonia at Equilibrium

Pressure (Atm ahs)

	10.38 7.35 5.25 3.85 2.80 2.04 1.61	10 30 10.38 7.35 17.80 5.25 13.35 3.85 10.09 2.80 7.59 2.04 5.80 1.61 4.53	$\begin{array}{cccccccccccccccccccccccccccccccccccc$		

5. An inspection of Table I, shows that a 1° change in the temperature produces about 1% change in the percentage of ammonia at equilibrium. Since the temperature was measured with an accuracy of 0.5° the errors from this source probably do not exceed 0.5%. This would produce approximately the same percentage error in the equilibrium constant.

From the above considerations it is evident that the maximum error in the equilibrium constant might reach 3%. It is believed that the probable error, however, is very much smaller than this.

#### Results

The equilibrium percentages of ammonia obtained for the temperatures and pressures studied are given in Table I. In Table II the constant for the expression  $K_p = \frac{p_{\rm NH_2}}{p_{\rm N_2}^{1/2} \times p_{\rm H_2}^{3/2}}$  has been calculated for each of the pressure and temperature conditions indicated in Table I.

# Thermodynamic Calculations

If experimental data were available showing the volume changes which the nitrogen-hydrogen-ammonia mixture undergoes for various conditions of temperature and pressure, it might be possible with the aid of the van't Hoff equation to formulate a single expression which would satisfy the data given in Table I. By means of such a formula one would then be able to compute the equilibrium percentage of ammonia for any other temperature and pressure. Haber's formula (I) has been used for this purpose and is probably quite exact for relatively high temperatures. Jost working at 915° in Nernst's laboratory found that the pressure effect was negligible. Undoubtedly the ammonia is sufficiently "perfect" a gas at this high temperature so that the effect of pressure be-

comes negligible. At somewhat lower temperatures, however, deviations from the "perfect" gas laws undoubtedly become sufficiently great so that the pressure effect cannot be wholly ignored. The only experimental evidence for this so far presented is that by Greenwood'(VII) in Haber's laboratory who showed that the equilibrium constants in the neighborhood of 537° did vary with the pressure. Greenwood found, however, that the constant increased as the pressure is decreased, an observation which is quite the opposite of that shown in Table II. It is reasonably certain, however, that equilibrium was not reached in Greenwood's experiments, so not much importance is attached to this apparent disagreement with our result.

 $\begin{array}{c} \text{Table II} \\ \text{Observed Equilibrium Constant} \\ ^{1}/_{2}N_{2} \, \div \, ^{3}/_{2}H_{2} \, = \, NH_{3} \end{array}$

500	.00381	.00386	.00388	.00402

Unfortunately, no data are at present available which make possible even a rough calculation of the extent to which the equilibrium constant might be expected to vary with the pressure. Whatever the pressure range covered, nitrogen and hydrogen are probably nearly "perfect" gases even at the lowest temperature studied. Although the temperatures studied by us are somewhat higher than those investigated by Roth, 12 the indications are that even at these temperatures the ammonia is still somewhat more compressible than a "perfect" gas, so that even if the magnitude of the effect cannot be predicted from present data, the effect as observed by us is certainly in the right direction.

For any given constant pressure, however, the van't Hoff equation  $\left(\frac{\partial \log K_p}{\partial T}\right)_p = \frac{Q_s}{RT^2}$  may be employed to treat the variation of the equilibrium constant,  $K_p$ , with the temperature. To integrate this expression it is first necessary to know how the heat of formation of ammonia from its elements varies with temperature. The integration constant may then be exactly evaluated from a single equilibrium determination, or approximately evaluated by means of Nernst's heat theorem. At present the heat

¹² Roth, Ann. Physik., [2] 11, 1 (1880).

of reaction and thermal properties of these gases are not known with sufficient accuracy to make possible the computation of equilibrium data by this method. Consequently, any formula which closely fits the observed data must of necessity be largely empirical.

Taking the best data available, Haber formulated the following expression based upon the reaction isochore, which he held to combine all the results of his equilibrium experiments and thermal determinations

$$\log K_p = \frac{9591}{4.571T} - \frac{4.98}{1.985} \log T - \frac{0.00046}{4.571} T + \frac{0.85 \times 10^{-6}}{4.571} T^2 + 2.10$$

This formula was largely derived from results obtained at 30 atmospheres.⁷ If we use the more recent data for the specific heats of the gases¹³  $c_{p_{\rm Hz}} = 6.50 + 0.0009 \ T$ ,  $c_{p_{\rm Nz}} = 6.50 + 0.0010 \ T$ , and  $c_{p_{\rm NHz}} = 8.04 + 0.0007 \ T + 5.1 \times 10^{-6} T^2$  and the heat of formation of ammonia at T = 0 as 9500,¹⁴ integration of the van't Hoff reaction isochore gives

$$\log \ K_{P} = \frac{9500}{4.5787T} - \frac{4.96}{1.9885} \log \ T - \frac{.000575}{4.5787} \ T + \frac{0.85 \times 10^{-6}}{4.5787} \ T^{2} + I$$

By choosing proper values for the integration constant and modifying the numerical coefficients we obtained empirical equations which fit our experimental data within the limits of experimental error. The constants and coefficients for the equations are given below. The equation has the

general form 
$$\log K_p = \frac{\alpha}{T} + \beta \log T + \gamma T + \delta T^2 + I$$
.

Pressure		150		8	
Atm.	α	β	γ	×107	I
10	+2074.8	-2.4943	0	+1.856	+1.993
30	+2074.8	-2.4943	$-3.4 \times 10^{-5}$	+1.856	+2.021
50	+2074.8	-2.4943	$-1.256 \times 10^{-4}$	+1.856	+2.090
100	+2074.8	-2.4943	$-1.256 \times 10^{-4}$	+1.856	+2.113

The observed data and those computed from these formulas are collected in Tables III and IV. For purposes of comparison we have included values computed from Haber's formula (see above). The observed results for temperatures above 500° were obtained by plotting Haber's experimental data and selecting from the curve the most probable values for the temperatures indicated.

Because of the interest attached to the Nernst heat theorem we have included in Table III values for 30 atmospheres, computed from his formula.¹⁵

In the absence of exact thermal data, calculation based on the Nernst heat theorem will, of course, give only an approximate evaluation.

500	1.21	3.49	5.56	10.61

equilibrium values for much higher pressures than those reported in this paper would, therefore, not be very exact. For any of the pressures studied however, equilibrium values for temperatures lower than those actually observed can probably be computed with considerable accuracy. Such computations have been made for temperatures down to 200°, the results of which are given in Table V.

#### Molecular Heat of Formation of Ammonia

Theoretically, it should be possible to calculate the heat of the ammonia reaction by means of the van't Hoff equation. By taking equilibrium constants for temperatures very close together and assuming that the temperature coefficient for those temperature intervals can be neglected, integration of the van't Hoff equation gives the heat of formation. Computations based on the constants in Table II have been made, the results of which are given in Table VI. For purposes of comparison we have also included the heat of formation as calculated by Haber from the heat absorbed during the "cracking" of ammonia. Since a 1% error in equilibrium constant makes an error of about 5% in the calculated heat of reaction, this method of determining thermal data cannot be considered very satisfactory. As Haber has pointed out16 thermal data obtained in this way can serve only as a check on the more direct experimental methods for reaction heats and specific heats. An inspection of Table VI will show that the attempt to formulate an expression for the heat of the reaction from these would be futile.

#### Summary

1. Equilibrium values for the reaction,  $N_2 + 3H_2 \rightleftharpoons 2NH_3$ , have been determined at 10, 30, 50 and 100 atmospheres' pressure for the temperature range of 325° to 500°.

¹⁶ Haber, "Thermodynamics of Technical Gas Reactions," Longmans, Green and Co., 1908, p. 65.

- 2. Equilibrium constants have been computed for each of the pressuretemperature conditions studied. These "constants" were found to increase with an increase in pressure.
- 3. By means of empirical formulas the percentage of ammonia at equilibrium has been calculated for a temperature range of 200–1000°, and a pressure range of 10–100 atmospheres.

# VAPOR PRESSURES OF LITHIUM CHLORIDE SOLUTIONS AT 20°

By B. F. Lovelace, W. H. Bahlke and J. C. W. Frazer Received September 22, 1923

This paper is a continuation of a series of studies of the vapor pressures of aqueous solutions begun by Frazer and Lovelace¹ using an accurate static method which depends upon the measurement of the difference in pressure between pure solvent and solution contained in bulbs immersed in the same accurately regulated water thermostat by means of a Rayleigh manometer. The error involved in measuring the pressure differences by this method is approximately  $0.0006 \, \mathrm{mm}$ . The measurements were made at  $20^{\circ}$  and in the concentration range from  $0.1 \, \mathrm{to} \, 1.0 \, M$ .

# Experimental Details

A detailed description of the apparatus used in this work is given by Frazer and Lovelace, ¹ and by Lovelace, Frazer and Miller. ² No change in the apparatus was made except to replace the Gaede pump with a Langmuir pump using a three-stage rotary oil pump as auxiliary.

The solutions of lithium chloride were prepared from a carefully standardized stock solution, the salt for which was purified as follows. A commercial c. p. grade of lithium chloride was dissolved in distilled water, a small amount of ammonium carbonate solution added and the mixture heated and stirred for four hours to precipitate any magnesium, calcium, barium, iron or aluminum possibly present, then filtered. The ammonium carbonate used in the preparation left no residue on sublimation. To the filtered lithium chloride solution, ammonium carbonate solution was added in slight excess and the lithium carbonate filtered off and washed thoroughly with hot water. It was then heated in a platinum dish at a sufficiently high temperature to volatilize any ammonium carbonate possibly present. The salt was then suspended in a small amount of distilled water and pure hydrochloric acid added until the solution was neutral to rosolic acid. Analyses of the solution for lithium and for chlorine checked within 0.04%.

In previous investigations the removal of dissolved air from the solutions has been quite a time-consuming operation. Tests for air in the solution or solvent were made by allowing it to come to equilibrium with a large

Frazer and Lovelace, This Journal, 36, 2439 (1914).

² Lovelace, Frazer and Miller, ibid., 38, 515 (1916).

volume of vapor above it for hours.³ The vapor was then trapped off and absorbed in phosphorus pentoxide for 20 minutes and the residual pressure measured on a McLeod gage. No solution was considered air-free unless the vapor showed a residual pressure less than 0.0001 mm. Usually the solutions had required from four to six 12-hour expansions before they were air-free. In the present investigation it was found that the air could be removed in a minimum of time, that is, one 12-hour expansion. This was accomplished by introducing the solution as nearly air-free as possible into the bulb which had been previously pumped air-free, and rapidly distilling a small portion of the solvent at the pressure of its vapor into a bulb containing phosphorus pentoxide.

In detail the method is as follows.

The solutions were made up in a flask shaped like that shown in Fig. 1. The required amount of the concentrated lithium chloride solution was introduced with a pipet

into the flask which had been weighed empty. Water sufficient to bring the solution to the desired concentration was then introduced, the level marked, and a small excess added which was later removed by boiling the solution in the flask in order to remove air. The upper tube of the flask was then constricted at the portion "a" and a clean rubber tube fixed over the end of the glass and fitted with a pinchcock. The lower limb of the flask was then cautiously heated with a Bunsen flame in order to expel from this portion of the solution as much air as possible. The flame was then applied to the sides of the flask and the solution vigorously boiled for 30 minutes or more until the level was down nearly to the mark on the flask. The pinchcock was then closed and the flame removed simultaneously, the solution allowed to cool slightly and the flask sealed off at the constriction. flask was then weighed and the weight of the solution noted, in order to determine approximately the concentration. Usually about 3 g. more water than that required for the concentration

desired was present. This excess allowed for removal of water by distillation after the solutions were in the bulbs in the bath.

The sealed flask was then fixed to a mercury reservoir as shown in Fig. 2, the tube broken at "a" by pressure of the fingers and the mercury allowed to complete the filling of the flask, the flow being regulated by a pinchcock. The tube was then fitted with a capillary filled with mercury and the tip broken at b, some of the solution being wasted to replace the mercury in the capillary. The solution was then introduced into the bath in the usual manner.⁴

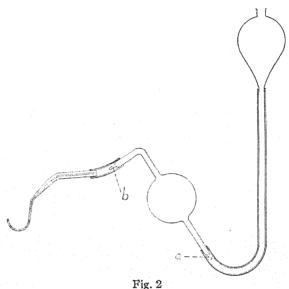

It was necessary to have the system free from air before introducing the solutions; this was accomplished quite readily by beginning the evacuation while the bulb and mercury seal were still wet. In this way a layer of water preceded the mercury up the tube leading to the bulb. The water was then removed by exposure to phosphorus pentoxide. The system was evacuated until no gain in pressure could be measured on the McLeod gage after the system had stood for 12 hours.

³ Lovelace, Frazer and Rogers, [This Journal, 42, 1794 (1920)] showed that 12 hours was necessary to establish equilibrium between solution and vapor.

⁴ Ref. 3, p. 1797.

After the solutions had been introduced into the system they were exposed to phosphorus pentoxide for a definite length of time until about 1 g. of water had been removed. It had been previously determined by experiment that the water distilled at a practically constant rate so that it was unnecessary to weigh the water removed.

The solution was then trapped off and the system evacuated to remove air given up by the solution. After distilling and evacuating the solutions thrice they were usually air-free, the whole operation requiring about 24 hours. By the method formerly used it required from four to ten days to remove the dissolved air.

In making readings of the vapor-pressure lowering, the accurate regulation of the temperature described in former articles was followed. Usually three readings of the zero point of the gage were made, three readings of the solution in the first bulb, three readings of the second solution and then two more readings of the zero. No readings were regarded as sufficiently accurate unless the zero before and after checked within 0.1 mm. scale deflection. Readings were made by two different observers extending over two or three days until four reliable sets of readings were obtained on each solution.

After the solutions were measured they were removed from the bath and placed in clean, glass-stoppered flasks and analyzed for chlorine. Concentrations (Table I) are expressed in moles of lithium chloride per 1000 g. of water.

#### Results

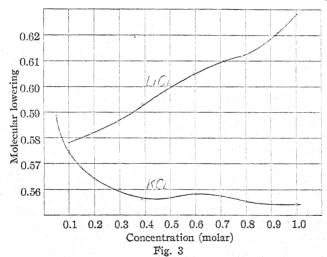

The results of the measurements are given in Table I. Col. 1 gives the room temperature, Col. 2 the concentration, Col. 3 the lowering as measured, Col. 4 the lowering corrected to millimeters of mercury at 0° and Col. 5 the lowering per mole.

The results are also shown graphically in Fig. 3 where the molecular lowering is plotted against the concentration. For comparison the data of Lovelace, Frazer and Sease⁵ on potassium chloride are shown in the same

⁵ Lovelace, Frazer and Sease, This Journal, 43, 102 (1921).

Moles LiCl per 1000 g. of water	Observed lowering Mm. Hg	Lowering corrected Mm. Hg at 0°	Molecular lowering Corrected observed lowering divided by Moles salt per 1000 g, of H ₂ O
0.0968	0.0562	0.0559	0.5775
0.1842	.1076	.1071	.5814
0.2952	.1738	.1730	. 5860
0.3862	.2300	.2290	.5929
0.4782	.2871	.2858	.5977
0.5897	.3582	.3566	.6047
0.7257	.4448	. 4428	.6101
0.7810	.4804	.4782	.6123
0.9268	.5775	. 5749	.6203
1.0316	.6518	.6489	.6290

figure. The curve for lithium chloride is considerably higher owing to the fact that this salt is highly hydrated in solution while potassium chloride is not. Although the degree of hydration decreases with increasing concen-

tration the apparent effect increases with concentration since the percentage of total solvent associated with the lithium chloride increases with the concentration.

An irregularity between 0.4 and  $0.8\,M$  similar to that found for potassium chloride⁶ is also apparent in the lithium chloride curve, but is masked somewhat in the latter case by the comparatively large slope of the curve.

In Table II the observed vapor-pressure lowerings at 20° have been compared with those calculated from the freezing-point measurements of Washburn and MacInnes.⁷ The ratio of the vapor pressure of the solution

⁶ Ref. 5, p. 106.

Washburn and MacInnes, This Journal, 33, 1701 (1911).

to that of the pure solvent at the freezing point was calculated by means of the equation⁸

$$\log \frac{N}{N+n} = \log \frac{P}{P_0} = \frac{\Delta C_P}{R} \log \frac{T_F}{T_0} \frac{-4343 (L_F - \Delta C_P \Delta T_F)}{R T_F} + \frac{0.4343 \ L F_0}{R T_{F0}}$$

where  $\frac{N}{N+n}$  is the mole fraction of solvent; P, the vapor pressure of the solution;  $P_0$ , the vapor pressure of pure solvent;  $T_F$ , the freezing point of the solution in degrees A.;  $T_0$ , the freezing point of solvent in degrees A.,  $= 273^\circ$ ;  $L_F$ , the molal heat of fusion of the solvent, = 1435.5 calories;  $\Delta C_F$ , the difference between the molal heat capacities of the solvent in liquid and solid state, = 9.05 calories;  $\Delta T_F$ , the lowering of the freezing point; R, the gas constant, = 1.985 calories.

Assuming that the ratio  $P/P_0$  is independent of the temperature the values given in Col. 3 of Table II were calculated.

		TABLE II		
Moles of LiCi		Po-		
per 1000 g. of water	$\Delta T_F$	From fp. measurements	Observed	Difference f. p.—obs.
0.1	0.351	0.054	0.056	-0.002
0.2	0.694	.115	.117	002
0.3	1.049	.178	.175	+ .003
0.4	1.416	.239	.236	+ .003
0.5	1.791	.311	.300	+ .001
0.6	2.174	.365	.365	.000
0.8	2.966	.499	. 485	+ .014
1.0	3.792	.633	.648	015

The agreement between the two is very good considering the fact that the salt is so highly hydrated in solution.

#### Summary

The lowering of the vapor pressure of water due to dissolved lithium chloride has been measured at  $20^{\circ}$  and in the concentration range of 0.1~M to 1.0~M.

An improved method for removing air from the solutions before measuring has been devised.

The observed vapor-pressure lowering has been compared with those calculated from freezing-point measurements.

EQUILIBRIA IN SOLUTIONS CONTAINING MIXTURES OF SALTS¹

- III. THE SYSTEM, WATER AND THE CHLORIDES AND CARBONATES OF SODIUM AND POTASSIUM AT 25°
- IV. THE SYSTEM, WATER AND THE SULFATES AND CARBONATES OF SODIUM AND POTASSIUM AT 25°

By Walter C. Blasdale Received September 24, 1923

Although the system composed of water and the chlorides and carbonates of sodium and potassium should find important applications in dealing with the problem of separating the salts of potassium from certain brines of both natural and artificial origin, it does not appear to have been investigated. The work here reported upon is limited to a single temperature, but much information relating to the system at both higher and lower temperatures has been accumulated and will form the subject of subsequent papers. The writer is indebted to Dr. Harry East Miller for assistance in carrying out a part of the analytical work which the investigation demanded.

#### The Solid Phases Concerned

The solid phases found to be concerned in this system are the chlorides of sodium and potassium, the decahydrate, heptahydrate and five-halves hydrate of sodium carbonate, the three-halves hydrate of potassium carbonate and a hydrated double carbonate of sodium and potassium. The identification of these salts by means of the microscope formed an important part of the work here described and it was found necessary to make many preparations of them and ascertain some of their more important crystallographic and optical properties.

The difficulties encountered in preparing such hydrates free from occluded mother liquor and in drying them without loss of combined water are very great. Large crystals, whose surfaces were perfectly dry, almost invariably gave appreciable amounts of a saturated solution when crushed in an agate mortar and although smaller crystals yielded less, it was difficult to eliminate it entirely. Since the vapor tensions of most of these hydrates have not been determined, it is not possible to define with accuracy the proper conditions for drying them. The procedure usually adopted was to prepare fine crystals by rapid cooling, through a few degrees, of a saturated solution, separate these on a coarse filter as rapidly as possible, wash with solutions of alcohol of increasing concentration and allow to dry spontaneously until the odor of alcohol could no longer be recognized.

¹ The preceding articles of this series will be found in *J. Ind. Eng. Chem.*, **10**, 334 (1918) and **12**, 164 (1920).

The Decahydrate of Sodium Carbonate.—Although this hydrate is the one usually obtained at ordinary temperatures, the available data regarding its crystallography are rather meager. This is probably due to the fact that it loses water under ordinary atmospheric conditions so rapidly that accurate measurements of the interfacial angles are difficult to obtain. A limited number of such measurements were made by means of a reflecting goniometer. They showed that the crystals were monoclinic: the value found for the \beta angle was 122° 42' instead of 122° 20', as calculated by Mohs.2 Adopting the axial ratios found by him, the only planes found in the prismatic zone were (110), (100) and (010). The most conspicuous terminal planes observed were (001), (101) and (111). When the crystals were caused to separate rapidly, columnar prisms terminated by the basal plane were obtained. When they were grown more slowly, tabular forms flattened parallel to (010) and terminated by (001) and (101) were formed. Under the microscope, such crystals gave a hexagonal figure with angles of 122° 42′ (100): (001), of 115° 50′ (001): (101), and of 121° 28′ (101):(001).

The birefringence is strong and extinction is parallel to (100) and hence divides almost equally the 115° 50′ angle. The three indices of refraction reported by Larson,³ namely, 1.405, 1.425 and 1.440, do not differ sufficiently from those of the related hydrates to make identification by means of these constants certain.

The Heptahydrate of Sodium Carbonate.—The crystallography of this salt has been investigated by Rammelsberg⁴ and others. It readily forms perfect crystals of good size which assume the form of tabular prisms of easily recognizable orthorhombic symmetry. From measurements of angles in the prismatic zone, assuming the axial ratios calculated by Rammelsberg, it was found that the faces usually present were (010), (230) and (100). Similarly, it was found that the predominant terminal planes were (111) and (021). As the crystals are usually flattened parallel to the brachypinacoid the usual outline presented on the stage of the microscope was that of a 6-sided figure showing angles of 128° 40′ and 115° 40′, or of an 8-sided figure showing angles of 154° 40′ and 115° 40′, or still more rarely, of a 4-sided rectangle. The extinction is parallel to (100) and bisects the 128° 40′ angle. This serves to distinguish it from the usual forms of the decahydrate.

Under ordinary atmospheric conditions, the salt readily loses water of crystallization and when heated forms a liquid and a new solid phase, probably the monohydrate.

The Five-halves Hydrate.—This salt usually separates in the form

² Mohs, Pogg. Ann., 5, 369 (1825).

³ Larson, U. S. Geol. Survey Bull., 679, 114 (1921).

[&]quot;Hand. d. kryst. Chemie," Suppl., Leipzig, 1857, p. 75.

of needles, but occasionally as long, 4-sided or flattened 8-sided prisms, terminated by a single pair of planes intersecting at 134°. The birefringence is strong and the extinction parallel. The percentages of water found in different preparations of it were 31.04, 31.30, 32.10, 31.54, 29.90, and 30.46. Many samples contained potassium in the form of carbonate from negligible amounts to as much as 4%. The theoretical percentage of water should be 29.80 and it is believed that the variations in its composition are due to a limited amount of solid solution formation.

The Double Carbonate of Sodium and Potassium.—The formation of a double carbonate of these elements was noted by Fehling,⁵ and somewhat later by Stolba,⁶ both of whom reported a composition corresponding to NaKCO₃.6H₂O. Marguerite⁷ has also reported a salt of the composition 2Na₂CO₃.K₂CO₃.18H₂O, and still more recently, Hugounenq and Morel³ reported that the double salt which separated from solutions containing large amounts of potassium iodide varied greatly in its composition and concluded that the hexahydrates of the two carbonates formed a series of isomorphous mixtures.

Many samples obtained from solutions, which varied greatly as to the relative amounts of the two carbonates, were submitted to analysis during the course of this work. Some of these are as follows.

	A	В	C	D	Calculated (NaKCO:.6H2O)
$H_2O$	48.10	47.69	47.09	46.65	46.96
CO ₃	26.04	25.90	25.94	26.83	26.06
K	13.80	14.78	16.66	13.46	16.99

These figures seem to justify the statement that there is a certain amount of solid solution formation represented in this solid.

Perfect crystals of short columnar or tabular habit, 3 cm. in length, were easily obtained, especially when the solution contained an excess of potassium carbonate. Measurement of the more important interfacial angles of 9 well-formed crystals gave values differing but slightly from the values reported by Marignac. The most strongly developed planes were (110), (010), (100), (011), (101) and (111).

When examined on the stage of the microscope, they usually lie on the prismatic face, and in this position give an extinction angle of 25°. The indices of refraction, determined in directions parallel and perpendicular to extinction by the embedding method, were 1.428 and 1.440. When heated slowly, the salt shows a clearly defined transition temperature of 34.5°, but it is readily formed at temperatures as low as zero.

The Three-halves Hydrate of Potassium Carbonate.—Analyses and microscopic examination of several preparations of this salt obtained during the course of the work showed that the only hydrate formed at 25° was the three-halves hydrate.

# The Vapor and Liquid Phases

In addition to the seven solids named above, this system is concerned with a solution phase and a vapor phase composed of water vapor plus the components of the atmosphere. Variation in the composition of the liquid phase must produce corresponding variations in the partial pressure of the water vapor in equilibrium with it, and these in turn must affect the partial pressures of the oxygen, nitrogen, etc., in the vapor phase. Although these variations affect the concentrations of the gases dissolved in the liquid phase, since the values concerned are too small when calculated in weight units to be classed as important constituents of the solution phase, they produce only insignificant effects upon the solubility of the solids concerned. Probably a much greater variation can be attributed to variations in the composition of the solids, due to solid solution formation and to occlusion. The partial pressure of the carbon dioxide normally present in the atmosphere is too small to affect, to a recognizable degree, the concentration of the acid carbonate, which results from hydrolysis of the soluble carbonates. Hence, the nature of the entire system is established with a high degree of accuracy by the composition of the liquid phase.

# Composition of the Liquid Phase

No essential departures were made from the procedure outlined in the former papers of this series in determining the composition of solutions

in equilibrium with the various solid phases. The thermostat used was kept constant to 0.1°. All determinations of potassium were made by separating and weighing as the chloroplatinate. Changes in the solid phases present were followed by a study of the crystal form and optical properties.

The composition of the saturated solutions finally obtained were calculated in terms of the number of grams per 100 g. of water and of moles per 1000 moles of water of the salts necessary to express its composition. The results are given in Tables I and II.

#### Graphical Representation of the System

Since the system represents a reciprocal salt pair, it can be represented graphically by the method of Löwenhertz as modified by van't Hoff, in which the composition expressed in terms of moles of Na₂Cl₂, K₂CO₃, K₂Cl₂ and Na₂CO₃ is plotted on two lines intersecting at 90°. The resulting diagram based upon the data of Table I is shown in Fig. 1, in which the letters represent "significant points." The positions of these points were fixed by averaging two or more results.

A large number of determinations, which are shown on the diagram as crosses, of points on the lines connecting significant points were found to be necessary to locate the course of these lines accurately. The departures from linear relations are in some cases surprisingly large.

As the hydrates here concerned readily form greatly supersaturated solutions and as long continued stirring was necessary to destroy this condition of supersaturation, great difficulty was found in correctly locating the limits of the fields on the left side of the diagram. The general course

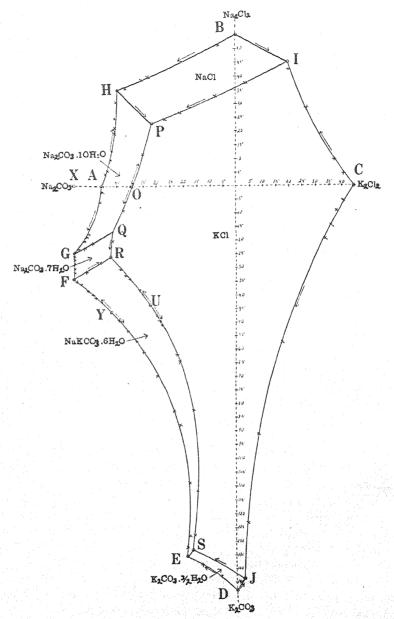

Fig. 1.—Equilibria between water and the carbonates and chlorides of sodium and potassium at  $25^{\circ}$ 

of the broken line A-G-F-E shows a satisfactory degree of agreement with a similar line determined by Kremann and Zitek¹⁰ at a temperature of ¹⁰ Kremann and Zitek, *Ber. Vinnee Akad.*, **11B**, 118 (1909).

24.2° as part of their work on the system, sodium carbonate-potassium nitrate. Since the solubility of the double salt is very greatly affected and that of the two hydrates of sodium carbonate is affected to a large extent by temperature changes, only rough agreement with their work in the location of the points G and F could be expected.

Although the five-halves hydrate frequently separated in solutions whose composition was represented by points along and beyond the limits of the line EF, no indications of a further break between A and E could be found in spite of the large number of determinations made. This salt also appeared in solutions corresponding to points in portions of the decahydrate, the heptahydrate, the double salt and the potassium chloride fields, but no definite limits within which it separated could be established, and the conclusion was reached that it was always metastable at this temperature.

The lines representing the changes in the composition of solutions which would result from evaporation at 25°, that is, the crystallization paths, have not been shown on the diagram, but their location can be indicated at least approximately with but little difficulty. For the fields representing solutions saturated with respect to Na₂CO₃.10H₂O, NaCl, KCl and K₂CO₃.3/₂H₂O, these lines must radiate from the points A, B, C and D respectively: for the heptahydrate field they must radiate from the point X, at the intersection of the lines CA and the prolongation of FG; for the double salt field they must radiate from Y, at the intersection of EF and the line bisecting the angle between AC and BD.

Each of the points A, B, C, D and Y represents a solution congruently saturated with respect to a single salt, and each of the points H, I, I, E and F a solution congruently saturated with respect to a pair of salts, but G is not congruently saturated. The points P, R and S represent solutions congruently saturated with respect to three salts, but Q is not a congruent solution although saturated with respect to three salts. Another congruent solution which is saturated with respect to the double salt and potassium chloride must be located on the line RS not far from Y. Its location can be fixed by the following procedure. From a study of the figures representing the composition of solutions on RS in the neighborhood of Y it can be estimated that the point in question should contain K2Cl2 to the extent of 11.8 moles. Starting at a point 11.8 units directly to the right of Y, and moving in a direction parallel to the diagonal bisecting the angle between AC and BD, the point at which RS is intersected, that is, the point U, will represent the one desired. Its composition, namely, 11.8 K₂Cl₂, 43.8 K₂CO₃, and 43.8 Na₂CO₃, is such that when evaporated it can lose double salt and potassium chloride in such proportions as to cause no change in its composition.

Still another congruent solution, which is saturated with respect to

Na₂CO₃.10H₂O and KCl, must be represented by a point on the line PQ. Since this solution must contain Na, CO₃, K and Cl in the same proportions as a solution prepared by dissolving sodium carbonate and potassium chloride in water, it must lie on the line AC. The point O therefore possesses the desired properties.

After having ascertained the locations of all the possible congruent solutions it can be predicted that all solutions represented by points lying above AC, except those on the periphery, will when evaporated ultimately attain the composition represented by P: solutions represented by points below YUC will reach S and those between these lines will reach R.

In conclusion it might be noted that this diagram illustrates the behavior of two kinds of congruent solutions. Those represented by H, I, J, E, F, P, R and S indicate the limiting values which can be attained in the composition of certain solutions when they are evaporated. They are crystallization end-points. Those represented by A, B, C, D, Y, U and O indicate points at which the character of the change in the composition of the solution resulting from evaporation changes abruptly. They are points from which certain crystallization paths take their origin.

# The System, Water and the Carbonates and Sulfates of Sodium and Potassium at 25°

The solid phases found to be concerned in the system, water and the carbonates and sulfates of sodium and potassium are, in addition to the carbonates described in discussing the chloride-carbonate system, potassium sulfate, the decahydrate of sodium sulfate and glaserite, a salt usually represented by the formula,  $3K_2SO_4$ . Na₂SO₄, but known to vary slightly as to the relative amounts of the two sulfates owing to the formation of a solid solution. The absence of anhydrous sodium sulfate from the entire system is worthy of comment. Possibly its absence is due to the formation of the sulfate carbonate of sodium to which the name "burkeite" has been given, which was found to separate at slightly higher temperatures. This salt may exist potentially in the form of complex ions at 25°, thereby reducing the concentration of the simple sodium ions and increasing the vapor pressure of the solution to such an extent as to prevent saturation with respect to the anhydrous salt. As in the former system, the fivehalves hydrate of sodium carbonate appears as a metastable phase only.

The composition of solutions saturated with respect to one or more of these solids is given in Tables III and IV, and a diagram based upon the data of Table III is given in Fig. 2. Very great difficulty was found in locating the line separating the potassium sulfate and glaserite fields, owing to the extreme slowness with which equilibrium was established in solutions whose composition corresponded to points near this line.

The crystallization paths for fields representing solutions saturated with respect to Na₂CO₃.10H₂O, Na₂SO₄.10H₂O, K₂SO₄, and K₂CO₃.³/₂H₂O must radiate from the points A, B, C and D. The form of the field for the solid Na₂SO₄.10H₂O is difficult to visualize without a space model of which Fig. 2 is only a projection. The paths for the heptahydrate of sodium

carbonate and the double carbonate fields must radiate from the points X and Y, whose positions are located by the construction indicated in the preceding system. Assuming that glaserite has a constant composition indicated by the formula given, the crystallization paths for the glaserite field must radiate from the point Z, obtained by prolonging IJ until it intersects a line representing solutions containing three times as many moles of potassium as of sodium sulfate. Owing to variations in the composition of this solid the directions of these paths can only be indicated with approximate accuracy.

The points A, B, C, D and Y must represent solutions congruently saturated with respect to a single salt and the points H, I and E with respect to two salts, but G and J are not congruently saturated. There must also be a point on the line connecting C and D representing a solution congruently saturated with respect to potassium sulfate and the three-halves hydrate of potassium carbonate, but its position is so near to D that it cannot be indicated properly on the diagram. Expressed otherwise the solubility of potassium sulfate in solutions saturated with potassium carbonate is negligible.

From a study of the directions of the crystallization paths it becomes obvious that the points P, S and T represent solutions congruently saturated with respect to three salts, but Q and R are not congruently saturated.

Another congruent solution, which is saturated with respect to potassium sulfate and the double carbonate, must be located on the line ST not far from Y. Its position can be fixed by the following procedure. Solution S contains 1.28 moles of potassium sulfate and T 1.4 moles; therefore a point on the line ST not far from Y might be expected to contain 1.3 moles. Starting from a point located 1.3 units to the right of Y and moving along a line parallel to the line bisecting the angle between AC and BD, the line ST will be intersected at U, which will represent the desired point. It contains in addition to 1.3 moles of  $K_2SO_4$ , 46.5 of  $K_2CO_3$  and 46.5 of  $Na_2CO_3$ .

Still another congruent solution must be located on the PQ line. Its composition can be established roughly by a series of approximations to be 59.5 Na₂CO₃, 4.2 Na₂SO₄, and 12.6 K₂SO₄. The point in question must be located not far from A but slightly above AC. The number of moles of sodium carbonate present can be estimated to be 59.5, basing the estimate upon the rate at which sodium carbonate changes between P and Q. Starting on AC at a point 59.5 units to the right of the origin and proceeding therefrom in a line parallel to the line which represents three times as many moles of potassium as of sodium sulfate it will be found that PQ is intersected at O. This point corresponds to the composition indicated above, and contains that number of moles of sodium carbonate and a total number of moles which its position with respect to

P and Q requires. This procedure involves rather large errors and assumes that the rate at which the composition of the solution changes along the line PQ is uniform as to sodium carbonate and the total number of moles present.

Having fixed the position of O it can be predicted that all solutions represented by points above AOZ except those on the periphery must finally attain the composition P when evaporated. Further owing to the fact that certain crystallization paths pass into the glaserite field from the potassium sulfate field there will be a small triangular area limited by the point C, the intersection of OZ and QJ and the line OZ representing solutions which have the same crystallization end-point. In a like manner it can be predicted that that portion of the diagram limited by the two areas already defined and the line YUC represents solutions for which the crystallization end-point is S, and those portions below the last named line represent solutions for which T is the crystallization end-point.

#### Summary

- 1. Certain optical and crystallographic properties of the hydrates of sodium carbonate and of the hydrate of the double sodium-potassium carbonate have been ascertained, which can be used in identifying these compounds by means of the microscope.
- 2. The solubility data necessary for the preparation of complete phase-rule diagrams for the systems H₂O-Na₂CO₃-KCl and H₂O-Na₂CO₃-K₂SO₄ at 25° have been determined.

# STUDIES RELATING TO METALLO-ORGANIC COMPOUNDS. IV. THE CONDUCTANCE OF TRIMETHYL STANNYL CHLORIDE IN MIXED SOLVENTS

By Charles A. Kraus and Willard N. Greer Received October 6, 1923

In preceding numbers of this series it has been shown that the alkyl tin halides are non-conductors when dissolved in solvents of the non-basic type and conductors in solvents of the basic type, I such as the amines and the alcohols. It has further been shown that the alkyl metal halides exhibit a marked tendency to combine with ammonia and the amines to form compounds having markedly higher melting points than either of the constituents. While in some instances two molecules of ammonia or amine may combine with an alkyl metal halide, in by far the greater number of instances only a single molecule is involved. Where two molecules of am-

Kraus and Callis, This Journal, 45, 2624 (1923).

² Kraus and Greer, ibid., 45, 3078 (1923).

monia or amine combine with an alkyl metal halide, one molecule is, as a rule, held rather loosely while the other is held much more firmly. This is well illustrated by the compounds of ammonia with trimethyl tin iodide, in which case one molecule of ammonia is lost readily at ordinary temperatures, while the second molecule cannot be removed by ordinary means, the compound subliming at higher temperatures or in a vacuum at lower temperatures.

It has been suggested that the electrolytic properties of the alkyl metal halides and of other similar compounds are due to the formation of a complex cation of the ammonium type; for instance, trimethyl tin chloride and ammonia combine to form the compound H₃NSn(CH₃)₃Cl, in which the trimethyl tin group is attached to pentavalent nitrogen.¹ This accounts for the absence of electrolytic properties in the case of the pure compounds, as well as in that of solutions of these compounds in non-basic solvents of higher dielectric constant. This view as to the constitution of these compounds may be checked up by studying the conductance of the alkyl metal halides in solution in non-basic solvents on the addition of varying quantities of a basic solvent such as an amine or an alcohol. In the present article data relative to a number of systems of this type are given.

#### Experimental Part

Measurements were carried out in the usual way, according to the Kohlrausch method, with such improvements as are commonly practiced at the present time. The cell employed for the measurements was that previously employed and described by Kraus and Kurtz.³ All measurements were carried out at  $25.00^{\circ} \pm 0.01$ .

Conductance of Trimethyl Tin Chloride in Nitrobenzene on Addition of Pyridine.—A 0.1 N solution of trimethyl tin chloride in nitrobenzene was prepared in the cell, by weighing 9.2234 g. of trimethyl tin chloride into

462.96 cc. of nitrobenzene. Pyridine was added to the nitrobenzene solution by means of a weight pipet of the type described by Kraus and Callis.¹ The cell was placed in the thermostat, pyridine was added in various amounts and the conductance of the solution measured. The results are given in Table I, which requires no further explanation.

The results are shown graphically as Curve I, Fig. 1.

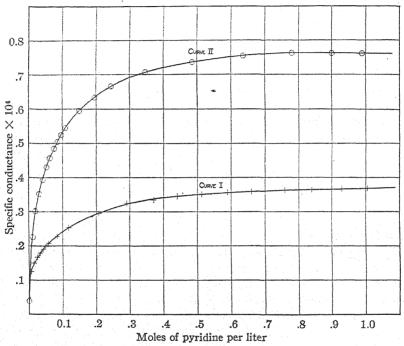

Fig. 1.—The increased conductance of solutions of trimethyl tin chloride in nitrobenzene (Curve I) and acetone (Curve II) on addition of pyridine

Conductance of Trimethyl Tin Chloride in Acetone in the Presence of Pyridine.—A 0.1 N solution of trimethyl tin chloride in acetone was prepared in the cell, with 7.7161 g. of trimethyl tin chloride in 387.32 cc. of acetone. The specific conductance of the acetone was  $7.4 \times 10^{-7}$ . Pyridine was added as before by means of a weight buret. The results are given in Table II.

The results are shown graphically as Curve II, Fig. 1.

Conductance of Trimethyl Tin Chloride in Mixtures of Acetone and Alcohol.—To a solution of 250 cc. of 0.1 N solution of trimethyl tin chloride in acetone prepared in the cell was added successively 25 cc. of 0.1 N solution of trimethyl tin chloride in alcohol, the conductance of the mixture on successive additions being measured. The same procedure

Conductance of Trimethyl Tin Chloride in Mixtures of Nitrobenzene and Pyridine.—Mixtures of pyridine and nitrobenzene were prepared as in the case of acetone and alcohol and the conductance of these mixtures measured. The pyridine was purified by treating 600 cc. of a sample which boiled at 116–118° with solid sodium hydroxide. The mixture was refluxed for 5 hours, the pyridine decanted and distilled. After three successive distillations a product was obtained which boiled at 115° and gave the value  $0.12 \times 10^{-6}$  for the specific conductance. The nitrobenzene was purified by redistilling a commercial product several times. A constant-boiling sample was obtained which gave a value of  $0.31 \times 10^{-6}$  for the specific conductance. The results are given in Table IV.

#### Discussion

In the tables the values of the specific conductance times 10⁴ are given. If in Tables I and II the change in volume due to the added pyridine is neglected, then the equivalent conductance will have the same numerical values as given in the column of specific conductances. If the volume change on mixing solutions of pyridine and alcohol and pyridine and nitrobenzene be neglected, then the values of the equivalent conductance are equal to the numerical values given under the columns headed specific conductance.

An examination of the tables and of the figures shows that the properties of solutions of trimethyl tin chloride in acetone and nitrobenzene are chiefly determined by the amount of pyridine which has been added. Considering the results of Tables I and II, shown in Fig. 1, it is seen that the addition of even a small amount of pyridine causes a very large rise in the conductance of the solution. Thus the addition of approximately 0.01 moles of pyridine to 0.1 moles of trimethyl tin chloride in acetone raises the conductance from 0.0389 to 0.225. With further addition of pyridine, further increase of the conductance takes place, so that on the addition of approximately one mole of pyridine the conductance reaches a value of 0.763. As may be seen from the curve, every successive addition of pyridine causes a smaller and smaller rise in the value of the conductance. What holds true of solutions in acetone on addition of pyridine equally holds true for solutions in nitrobenzene on addition of the same compound. This form of the curve is in harmony with the view that the electrolytic properties of these solutions are due to the formation of a salt-like compound between trimethyl tin chloride and pyridine. The values of the ionization in the different solvents can be compared only roughly. The specific conductance of a 0.1 N solution of trimethyl tin chloride in nitrobenzene containing approximately one mole of pyridine is 0.368, while for a corresponding solution in acetone it is 0.763. The fluidity of nitrobenzene at 25° is approximately 54.3, while that of acetone is 304 at 18°. In other words, the fluidity of acetone is about 6 times that of nitrobenzene. In proportion to the fluidity of the solvent medium, therefore, solutions of trimethyl tin chloride in the presence of pyridine are relatively better conductors in nitrobenzene than in acetone, corresponding to the relatively greater dielectric constant of nitrobenzene.

Considering Fig. 2, Curve IV, it is seen that the conductance of  $0.1\,N$  solutions of trimethyl tin chloride in mixtures of nitrobenzene and pyridine exhibits a maximum in the neighborhood of 42 volume per cent. of pyridine. The fluidity of pyridine is markedly higher than that of nitrobenzene. It follows, therefore, that the ionization of trimethyl tin chloride in the mixtures lies still nearer the axis of nitrobenzene.

The initial additions of pyridine to nitrobenzene cause a very marked

increase in the conductance due to the formation of the complex ammonium salt,  $C_6H_5NSn(CH_3)_3Ci$ . The addition of nitrobenzene to the pyridine solution causes an increased conductance as a result of increased ionization due to the greater dielectric constant of nitrobenzene.

The form of the curve for mixtures of acetone and alcohol, as shown in Fig. 2, differs markedly from that for mixtures of nitrobenzene and pyridine. The initial additions of alcohol to acetone cause a marked increase of conductance very nearly as a linear function of the volume composition of the solution. In view of the fact that the fluidity of acetone is much higher than that of alcohol, this indicates a marked increase in the ionization of the electrolyte. The effect, however, is much less marked than it is in the case of mixtures of pyridine and nitrobenzene or pyridine and acetone. Probably acetone itself forms a complex oxonium compound in solution to some extent: and, while alcohol, without doubt, forms a complex oxonium compound with trimethyl tin chloride, it is, in all likelihood, much less stable than the corresponding pyridine compound, which is in agreement with the fact that trimethyl tin chloride is obtained in the pure state on evaporation of the alcohol, whereas in the case of pyridine a compound remains behind. The initial additions of acetone to the alcohol solution cause a marked decrease in the conductance due, without doubt, to a markedly decreased ionization. This is probably in part due to a decrease in the dielectric constant, but probably even on addition of small amounts of acetone the equilibrium of the complex may be measurably affected. In this connection it should be noted that the conductances of solutions containing larger amounts of alcohol are, without doubt, measurably affected by the presence of water. The conductance of a 95% alcohol solution, without addition of acetone, is much higher than would correspond to the conductance of a solution in absolute alcohol, according to measurements recorded by Kraus and Callis,1 thus indicating a marked influence of water on the conductance of trimethyl tin chloride in al-

Similar changes in the conductance of solutions on addition of suitable substances have previously been recorded in a few instances. In the first place, solutions of salts, which show a marked tendency to take up water of crystallization, exhibit a low degree of ionization in non-aqueous solvents and their ionization is greatly increased on addition of water or an alcohol. This is particularly noticeable in the case of calcium nitrate on addition of water and the alcohols to solutions in acetone. Lithium salts exhibit a similar, although less marked, behavior.

These cases, however, are not strictly analogous to those which form the subject of the present investigation. The behavior of the acids in various non-aqueous solvents on addition of water forms perhaps a much closer

⁴ Jones, Bingham and McMaster, Z. physik. Chem., 57, 193, 257 (1906).

analogy with that of the alkyl metal halides. It has been shown that the ionization of the acids in the alcohols is greatly increased on addition of water. This effect has been ascribed to the formation of a compound of the oxonium type, which is more highly ionized than the pure acid⁵ or, perhaps better, the alcoholated acid.

Trimethyl tin chloride, as has previously been pointed out, exhibits properties which resemble those of the halogen acids very closely. They are non-conductors in the pure liquid condition, 6 as well as in solvents of the non-basic type, they are conductors in solvents of the basic type, or in solvents of the non-basic type to which small quantities of solvents of the basic type have been added, they are relatively weakly ionized in solvents of the mean dielectric constant, and they conform to the law of mass action in solvents of relatively high dielectric constant. What is true of trimethyl tin chloride is, without doubt, also true of other metallo-organic compounds of the type  $M^nR_{n-1}X$ . The properties of these compounds may be accounted for on the assumption that the group (CH₃)₃Sn occupies an intermediate position in the potential series, which brings it into the same class with hydrogen. Indeed, the group in its compounds resembles hydrogen much more closely than do the elements which occupy a corresponding position in the potential series, owing to the fact that the groups are univalent, while the corresponding elements have a relatively high valence. However, as was pointed out by one of the present authors, these elements likewise exhibit the property of acting amphoterically, that is, either positively or negatively, which is also a property of hydrogen and of groups of the type of the trimethyl tin group and other similar groups, as will be shown in a subsequent article.

⁵ Goldschmidt, Z. physik. Chem., 89, 132 (1915). Kailan, ibid., 89, 678 (1915). Braune, ibid., 85, 170 (1913).

⁶ Substances which are not marked conductors of the electric current in the pure liquid condition are not to be classed as true electrolytes, even though solutions of such substances in certain solvents may exhibit electrolytic properties. Present evidence indicates that the electrolytic properties of such substances in solution are due to the formation of new compounds which are true electrolytes. No term has thus far been suggested to distinguish substances of this type from true electrolytes; that is, substances which are ionized in the liquid condition as well as in solution. It is suggested that the term pseudo-electrolyte might be employed to distinguish the class of substances here under discussion from the true electrolytes. This prefix is now commonly used to distinguish between the true acids and certain organic substances which exhibit acidic properties in solution due to a rearrangement. The extension of the use of this prefix to compounds other than the acids should lead to no confusion, while at the same time it would serve to characterize a class of substances which is widely represented. A pseudo-electrolyte would thus be a compound which itself does not exhibit electrolytic properties but which reacts with certain solvents to form a new compound which is a true electrolyte.

⁷ Kraus, Rec. trav. chim., 42, 588 (1923).

#### Summary

The conductance of solutions of trimethyl tin chloride in nitrobenzene and acetone on addition of small amounts of pyridine has been measured. A marked increase takes place in conductance on addition of pyridine, and this effect is the greater, the smaller the amount of pyridine already present.

The conductance of solutions of trimethyl tin chloride in mixtures of 0–100% of acetone and alcohol and nitrobenzene and pyridine has been measured. The initial conductance in nitrobenzene is extremely low, indicating that trimethyl tin chloride is practically un-ionized in this solvent. The initial conductance in acetone is markedly higher than in nitrobenzene. While the conductance in acetone on addition of alcohol is increased, this increase is much less marked than it is on addition of pyridine.

The results are in agreement with the view that trimethyl tin chloride itself is not a true electrolyte and that its electrolytic properties in solution are due to the formation of compounds of the oxonium and ammonium type, the trimethyl tin group transferring from chlorine to tetravalent oxygen or pentavalent nitrogen, respectively.

#### THE ATOMIC WEIGHT OF LEAD FROM THE BELGIAN CONGO

By Theodore W. Richards and Paul Putzeys¹
Received October 11, 1923

The fundamental relation of the isotopes of lead to the process of radioactive disintegration gives an especial interest to the atomic weights of these isotopes. The difference in the geological histories of uranium deposits in different parts of the world makes it especially desirable that the quantitative relations of the lead in deposits from as many widely separated localities as possible should be examined. Within the past few years, as is well known, a new source of uranium and radium material has been found in the Belgian Congo. Accordingly, we have investigated the atomic weight of lead derived from this source.

The metal employed was obtained from a mixture of several minerals existing in the center of Africa. These all doubtless originated in a common primary deposit of uraninite, of which an analysis has been published.^{2a} Among the decomposition products of this primary mineral, Schoep^{2b} has discovered several secondary minerals containing lead, namely, curite (2PbO.5UO₃.4H₂O), kasolite (3PbO.3UO₃.3SiO₂.4H₂O), dewindtite (4PbO.-8UO₃.3P₂O₅.12H₂O) and stasite (4PbO.8UO₃.3P₂O₅.12H₂O). In all these

minerals, the lead was probably chiefly derived from the uraninite—the end-product of a large amount of uranium which had undergone disintegration. The specimen upon which we worked was from a mixture of all these minerals, and was obtained through the kindness of Professor W. Mund, of Louvain, Belgium. Monsieur Clérin, chief chemist of the Hoboken plant of the Compagnie minière du Katanga, has since been so kind as to give us larger amounts of the same material; to both we express our hearty thanks. This lead apparently may be available in quantity, and may therefore be used for a great variety of large scale experiments on the comparison of isotopes. For this reason, especially, a determination of its atomic weight is of value. A qualitative test by means of the gold-leaf electroscope showed appreciable radioactivity.

The method of determination adopted in the present research was essentially the same as that used by Baxter and his assistants³ in the study of the atomic weight of ordinary lead, and by others in this Laboratory for the determination of the atomic weight of uranium lead.⁴ For this reason a very brief account suffices.

#### Purification of Materials

The methods employed for the purification of nitric acid, water and the several gases used in the work needed no variations from the usual procedure. The silver we owe to the kindness of Dr. Norris F. Hall, who prepared a large quantity of the metal in a very pure state for coulometric work several years ago.⁵

The preparation of the lead deserves more detailed treatment. For comparison with the radioactive sample and for practice, a small sample of ordinary lead chloride was prepared from c. p. lead nitrate (once recrystallized) by precipitation in dilute solution by hydrochloric acid. The chloride was recrystallized twice from slightly acidified water. Although not very thoroughly purified, it was pure enough to serve as a basis for practice analyses and to show that the details of the analytical process were well in hand. This was designated as Specimen A.

The radioactive metal (which had been already purified considerably by commercial methods) was dissolved in pure nitric acid, the solution filtered and evaporated, and the lead nitrate recrystallized thrice, the last of these recrystallizations being conducted in quartz dishes. The solution of the purest nitrate was filtered again through a Gooch-Monroe platinum crucible, and subsequently lead chloride was precipitated from it by pure hydrogen chloride. After two recrystallizations (using purest water and quartz dishes) the recrystallized lead chloride was carefully dried for anal-

  - ⁵ Richards and Hall, This Journal, 39, 531 (1917); 38, 2045 (1916).

ysis; it constituted Sample B. From the mother liquors of this preparation, the residual chloride was precipitated by concentration and by addition of hydrochloric acid, and was recrystallized. It was then converted into the nitrate by repeated evaporation with the purest nitric acid, and the nitrate was recrystallized thrice from very acid solutions. Two more recrystallizations as nitrate from the purest water and filtration through a Gooch-Monroe crucible provided a very pure solution of the nitrate, which was precipitated by a solution of the purest hydrochloric acid. Three recrystallizations of the lead chloride from the purest water acidified with a few drops of hydrochloric acid (with centrifugal draining, as usual) yielded a preparation C. This specimen was doubtless purer than Specimen B, having received much more careful treatment and many more recrystallizations. The several samples were kept dry in quartz dishes in desiccators containing solid caustic alkali.

#### Method of Analysis

Seven analyses were made of these several samples. The method may be very briefly outlined.

The lead chloride was fused in a platinum boat in a current of pure hydrogen chloride. This gas having been displaced by pure nitrogen during the cooling, the product was finally enclosed in a weighing bottle in a current of pure dry air by means of the well-known bottling apparatus usually employed in such work. In every case the fused lead chloride was entirely colorless and transparent; but upon dissolving it in warm water slightly acidified with nitric acid in a suitable Erlenmeyer flask, traces of insoluble black residue were found floating on the surface of the water, especially in Specimens A and B. This impurity was collected on a tared Gooch-Monroe crucible, and weighed, and the weight was duly subtracted from the weight of the chloride. The average weight

of the contamination, the nature of which was not determined, was (counting all determinations) less than 0.2 mg., and in the last two (the most important) determinations, less than 0.1 mg. The platinum boat was weighed before and after each analysis and its average loss of weight found to be only 0.07 mg.

The clear solution of the lead chloride used occupied a volume of about 1.5 liters; it was precipitated with a suitable weighed amount of purest silver which had been dissolved, with the usual precautions, and the end-point was adjusted with the help of a few cubic centimeters of very dilute standard solutions of silver nitrate and hydrochloric acid by means of a nephelometer.

The rough preliminary analyses of ordinary lead chloride (Nos. 1, 2 and 3) for which no great accuracy is claimed, nevertheless yielded results (in average 207.18) sufficiently concordant with themselves and with the accepted value of the atomic weight of lead, 207.20, for the present purpose. The two following analyses upon the Congo lead (Nos. 4 and 5) likewise suffered from minor defects and were made with material only roughly purified. On the other hand, the final analyses (Nos. 6 and 7) were made with material far more carefully purified, and every step of each analysis was satisfactory. The loss in weight of the platinum boat and the weights of black residue were so small as to be practically negligible, and the end-point test in the nephelometer was unusually satisfactory. Further analyses seemed to be unnecessary, since these left nothing to be desired.

Evidently, lead from the uranium deposits in the Congo has an atomic weight exactly one unit less than the atomic weight of ordinary lead, and perhaps only 0.14 unit higher than that of pure uranium lead. Apparently, then, we may infer (assuming that the material contains nothing but a mixture of uranium lead and ordinary lead) that about 88% of the material under investigation consisted of uranium lead, and only 12% of ordinary lead. This is a far lower percentage of ordinary lead than that existing in the similar metal from Australia. The result leaves little room for doubt that the lead which forms an integral part of the four new radioactive minerals was really derived chiefly from uranium lead. The uranium lead from the disintegration must afterwards have combined chemically with much of the residual undisintegrated uranium. Clearly, these minerals must have been formed long after the original deposit of uraninite crystallized in its bed. In this case, as in others, a careful study of the atomic weight of the mixed isotopes in relation to the coexistent minerals thus affords an interesting clue concerning the geological history of the region.

In conclusion we are glad to express our indebtedness to the Education Foundation of the Commission for Relief in Belgium and to the Carnegie Institution of Washington for pecuniary assistance.

#### Summary

The atomic weight of a sample of radioactive lead obtained from a mixture of minerals found in radium ore from the Belgian Congo was determined as 206.20, as compared with a control sample of ordinary lead which gave the value 207.18. Evidently, therefore, the lead in these minerals consisted chiefly of uranium lead; and the minerals must have been formed long after the original deposit of uraninite.

Cambridge 38, Massachusetts

#### NOTES

A New Light Filter.—As far back as 1904 I observed accidentally that a solution of ordinary chrome alum of a proper concentration and thickness of layer is admirably adapted for detecting the potassium flame when it is masked by the presence of an excess of sodium light. It was found later by Mr. William D. Pardoe, a graduate student working in my laboratory, that it was possible to prepare a light filter with a solution of chrome alum which absorbs *completely* not only sodium light but that of lithium, strontium, calcium and barium. Viewed through such a filter the potassium flame is seen to rise from the glowing platinum loop in the form of a long, crimson, very bright streamer when a relatively large amount of this element is present, and less so, but always perceptible, as the quantity diminishes. Under the circumstances the flames of rubidium and cesium are also visible, but since these elements occur only in a few localities and in the minutest amounts, they are not apt to mislead one.

The filter is as sensitive as it is reliable and will keep indefinitely. One which has been in use off and on for fifteen years is as efficient today as it was when first prepared. In some cases, it has proved even more reliable than a Browning direct vision spectroscope. Such a filter is very handy in testing for potassium in the residues obtained by the evaporation of mineral and other waters, and in examining mineral silicates and silicate rocks for this element. Insoluble siliceous materials should be finely powdered, mixed with (a) pure gypsum or (b) four parts of pure calcium carbonate and one part of resublimed ammonium chloride, and the mixture made into a thick paste with water. A bit of the paste is then collected in a loop on the end of a platinum wire, brought into the fusion zone of the Bunsen burner, and the flame viewed through the filter.

To prepare a number of these filters (they will be found very useful in the laboratory for qualitative analysis), dissolve 310 g. of crystallized chrome alum in a large flask in a liter of water by gentle heating, cool and filter the solution and fill with it glass bottles of square prismatic form. Those used by me are 10 cm. high from bottom to shoulder, and the lateral edge measures 4.7 cm. Ordinary wooden corks will serve as stoppers. The filter is best held upright, very close to the eye, and about 5 or 6 cm. from the flame of the burner.

A Possible Reconciliation of the Octet and Positive-Negative Theories of Chemical Combination.—I have recently had the opportunity of reading, in proof, the monograph by Professor G. N. Lewis on "Valence and the Structure of Atoms and Molecules" which has just appeared as a volume of our Scientific Series of Monographs. One of the most fundamental concepts of the theory proposed by Professor Lewis is that a pair of electrons forms the bond which holds two atoms in combination. In nearly all reactions, whether those of electrolytes in solutions or of organic or other compounds, two atoms of one compound separate and combine with two atoms of some other compound. The atoms of the second compound must also separate. Professor Lewis has not, I think, discussed what happens to the electrons in these processes of separation and recombination.

Two methods of separation between two atoms held together by a pair of electrons seem possible: one electron may remain with each atom, leaving both atoms electrically neutral; or the pair of electrons may remain with one of the atoms, which will in that case be negative, while the other atom will be positive. It will be admitted by everyone that electrolytes react in the second manner. There are many considerations which point to the conclusion that many other compounds react in a similar manner.

In the case of hydrogen, it is generally agreed that the hydrogen atoms of acids separate from oxygen, or some other element with which they are combined, without any electron. Since we have among the organic compounds all degrees of ionization from that of strong acids to that of substances like ethyl alcohol, which ionize even less than water, and since ionic hydrogen is very easily transferred from oxygen to carbon and vice versa, in tautomeric compounds, we seem to be justified in assuming that in nearly or quite all reactions hydrogen atoms separate from carbon in the positive form and the carbon atoms from which they separate must, therefore, be left in the negative form. In this sense that they either cling to or give up easily the pair of electrons which unites them to other atoms, carbon and other atoms in organic compounds are either positive or negative. This point of view is often useful in predicting the course of a reaction. For instance, in the addition of ammonia, hydroxylamine, phenylhydrazine or the Grignard reagent to aldehydes or ketones, the hydrogen or magnesium always adds itself to the oxygen atom, which clings obstinately to the pair of electrons. In the hydrolysis of cyanides, R-C=N, the nitrogen atom clings to the electrons and the hydrogen atoms attach themselves to that, while the negative hydroxyl adds itself to the carbon.

In the separation of two carbon atoms in breaking the double union of the type R—CH:: CH₂, the pair of electrons clings chiefly to the end

carbon atom, which becomes, in that way, negative and the hydrogen adds to that, while the bromine or iodine of hydrobromic or hydriodic acid adds to the second, positive carbon atom. In a similar manner, when nitrogen trichloride adds to the same compound, the positive chlorine adds to the end carbon atom while the negative nitrogen atom of the nitrogen dichloride group adds to the second carbon atom.¹

The theory here presented does not require us to assume that in a molecule of chlorine, Cl: Cl, one of the chlorine atoms is positive and the other negative. It does assume, however, that when the molecule separates into two atoms, in a reaction with some other compound, the pair of electrons usually remains with one of the atoms, which is therefore negative, while the atom which separates without the electrons is positive.

The theory does not require us to suppose, either, that an atom which enters a molecule in a positive form must necessarily leave the molecule in the same form. Thus, in the addition of hypochlorous acid to ethylene the positive chlorine atom is added to one of the carbon atoms and the negative hydroxyl to the other.² But the ethylene chlorohydrin, CH₂Cl—CH₂OH, formed hydrolyzes to glycol, CH₂OH—CH₂OH, and hydrochloric acid. The chlorine adds in the positive form and splits off in the negative. Such a result seems quite natural according to the theory as here presented, but it is rather difficult to account for by the positive-negative theory as it has often been interpreted.

The view here presented is closely related to a suggestion made in the author's address before the St. Louis Congress of Arts and Sciences, namely, that molecules separate into positive and negative ions as they react with each other.³

In the foregoing, no attempt has been made to consider the kinetics of the binding pairs of electrons. The success which has attended the application of the theories of Bohr and Sommerfeld to explain the spectral lines of hydrogen and helium inclines most physicists to the view that the electrons of atoms are rotating in orbits around positive nuclei. At a meeting of the Faraday Society in Cambridge, England, in July, Professor Sidgwick suggested that two atoms may be held together by two electrons rotating about the positive nuclei of the two atoms. A somewhat similar suggestion was made by the author some time ago.⁴ It is possible that some such hypothesis may ultimately be put on a sound basis and connected accurately with experimental facts, but at present it can be considered only as a very wild guess. It is somewhat in line with the theories

¹ G. H. Coleman, private communication.

² For reasons for believing that hypochlorous acid may easily separate into positive chlorine and negative hydroxyl, see Noyes and Wilson, This Journal, 44, 1630 (1922).

of the physicists and it seems quite certain that at some future time our theories of chemical combination must be brought into harmony with the known facts about spectral lines, absorption bands, color and other phenomena of light and radiation.

CAMBRIDGE, ENGLAND Received September 4, 1923

WILLIAM A. NOVES

A Method for Reproducing Graphs in Quantity.—Graphs, etc., are plotted with waterproof india ink on the ordinary graph (or coördinate) paper. This is dipped in a saturated solution of purified, colorless paraffin oil (such as Stanolind-Liquid Paraffin) in chloroform and allowed to stand for  $^{1}/_{2}$  to 1 minute. It is then removed from the solution and allowed to drain as long as convenient. The excess of oil is wiped off and the sheet allowed to dry in the air until ready to use.

Using paper thus prepared, as a negative, photographic copies can be made on any of the bromide or blue print papers by direct printing. The bromide reproductions are particularly satisfactory and resemble photostats.

# THE BEHAVIOR OF MERCURIC SALTS OF ORGANIC ACIDS TOWARD HEAT

By Morris S. Kharasch² and Frederick W. Staveley³ Received October 28, 1922

In a previous communication Kharasch⁴ called attention to the fact that mercuric salts of certain aromatic carboxylic acids when heated split off carbon dioxide and the mercury becomes attached to the carbon originally bound to the carboxyl group. That reaction is applicable only to those aromatic carboxylic acids which split off carbon dioxide at their respective melting points or at slightly higher temperatures. In the case of the mercury salts of aromatic carboxylic acids, which do not split off carbon dioxide

  - ² National Research Fellow in Organic Chemistry.
- ³ The material presented here is used by F. W. Staveley in his dissertation presented in partial fulfilment of the requirements for the Degree of Doctor of Philosophy at the University of Chicago.
  - 4 Kharasch, This Journal, 43, 2238 (1921).

readily, the mercury usually becomes attached to a carbon of the benzene ring.  5 

The extent to which these reactions find their parallel in the aliphatic series has been the subject of an extensive investigation by Kharasch and various collaborators. The present communication deals primarily with the behavior toward heat of various substituted acetic acids. In selecting the compounds for this work, we were guided by the following considerations. We wanted to ascertain, first, the behavior toward heat of mercuric salts of substituted acetic acids not containing a replaceable hydrogen atom on the  $\alpha$  carbon atom; second, whether in phenylated acetic acids the velocity of mercuration of the benzene nucleus is greater than that of the  $\alpha$  carbon atom; third, the behavior of mercuric salts of substituted acetic acids that decompose readily into carbon dioxide and hydrocarbon.

The only work known to the writers which has been carried out on the behavior of mercuric salts of aliphatic acids toward heat is that of Dimroth.^{6,7} This author claims to have obtained a mercurated acetic acid by heating mercuric acetate, the reaction proceeding thus:

$$(H_3C.COO-)_2Hg \xrightarrow{\text{heat}} H_2C \cdot CO+H_3C.COOH$$
. It can also be stated with  $H_2C$ .

a fair degree of certainty that most of the mercury salts of aliphatic acids containing one or more hydrogen atoms on the  $\alpha$  carbon atom would behave in the same way, the mercury replacing one of the hydrogen atoms of the  $\alpha$  carbon atom. However, when the hydrogen atoms on the  $\alpha$  carbon atom are replaced by other groups, the reaction that takes place depends upon the character of the substituting radicals. Thus far, the investigation in this direction with salts of acids which do not split off carbon dioxide readily, has been confined to the study of various substituted acetic acids, namely, trimethyl-, trichloro-, phenyl-, diphenyl- and triphenylacetic acids.

In the case of the mercury salt of trimethylacetic acid, no change takes place when it is heated in a vacuum to 240° for 20 minutes, except that some of the salt distils. Thus, the salt still gives a precipitate of yellow mercuric oxide when treated with sodium hydroxide, and its behavior in other ways

 $^{^{5}}$  It is usually assumed that in substituted benzoic acids the mercury enters ortho to the carboxyl group. (See Whitmore, "Organic Compounds of Mercury," Chemical Catalog Co., 1921, p. 295, for references.) However, this is not rigidly correct. Thus, by heating the mercury salt of p-nitrobenzoic acid the mercury enters not only ortho to the carboxyl group, but also meta to it. This latter product has been overlooked by previous investigators.

⁶ Dimroth, Ber., 35, 2870 (1902).

⁷ The behavior of mercuric cyanide when heated is discussed later in the paper.

⁸ The mercury salts of methyl-, dimethyl- and ethylacetic acids have been found to give products of that type. They will be reported by one of us (Kh.) in connection with another investigation.

resembles that of mercury trimethylacetate. Similarly, when the salt is heated above its melting point in the air, no change can be detected by chemical means.

However, when all three hydrogen atoms of acetic acid are replaced by chlorine atoms, as in the case of trichloro-acetic acid, an entirely different reaction takes place. It must also be stated at the outset that our experience with the mercuric salt of trichloro-acetic acid is not in agreement with that of the previous investigator⁹ of this salt. We could not isolate the mercury salt by dissolving mercuric oxide in a water solution of trichloro-acetic acid, although it must have been formed, since the solution gave a precipitate of mercuric oxide when treated with sodium hydroxide. The solution of the salt, however, was found to be unstable and when heated, or concentrated in a vacuum, or even allowed to stand for any length of time, mercurous chloride separated, and carbon dioxide was evolved. 10,11

If we replace the hydrogen atoms in acetic acid by phenyl groups, instead of methyl or chloro, the decomposition reactions which the mercury salts undergo upon heating are different. Thus, when the mercury salts of phenyl- and diphenylacetic acids are heated slightly above their melting points, the mercury does not replace a hydrogen atom of the  $\alpha$  carbon atom, but one of the benzene ring. In that respect this reaction resembles the mercuration of aromatic acids by the dry heating of the salts of the latter compounds. In the case of triphenylacetic acid the reaction is more complicated; one of the products of the reaction is, however, a nucleus-mercurated triphenylacetic acid.  12  In no case is any product formed which contains the mercury on the  $\alpha$  carbon atom. It appears, thus, that in

⁹ Clermont, Compt. rend., 76, 774 (1874).

¹⁰ The reaction undoubtedly proceeds in two or more stages, the decomposition in the molecule beginning with the mercury oxidizing the carbon, and thus giving rise to

the following products:  $(Cl_3C.COO-)_2Hg \xrightarrow{12.0} 2$   $(Cl_3C.COOHg) + Cl_3C.COOH + (Cl_3C.OH) + CO_2$ . The trichlorocarbinol thus formed decomposed immediately into phosgene and hydrogen chloride. The decomposition of the former product in water then proceeds in the usual manner. The non-formation of chloroform in this reaction precludes the possibility that hexachloro-mercury dimethyl is an intermediate product in this reaction.

¹¹ This behavior of the mercuric salt of trichloro-acetic acid is somewhat similar to that of the mercuric salt of oxalic acid (from the electronic point of view the two acids are similar) since the mercuric salt of the latter acid when treated with ammonium chloride breaks down when warmed, into ammonium oxalate, carbon dioxide and mercurous chloride. [Souchay and Lennsen, Ann., 102, 42 (1857).] The ferric salt of oxalic acid is also known only in solution [Doberiner, Ann., 122, 113 (1862). Lemoine, Compt. rend., 116, 982 (1893)] and it decomposes very readily into ferrous oxalate and carbon dioxide. The behavior of the salts of these easily oxidizable acids is under investigation by one of us.

¹² This is most interesting in view of the fact that in pyridine solution the salt decomposes into triphenylmethyl and metallic mercury. See Ref. 4.

the case of phenylated acetic acids, the velocity of mercuration of the nucleus is much greater than that of the side chain. 13

From the considerations thus far developed it is quite evident what course the decomposition of a mercury salt of a substituted acetic acid of a given type would take. However, there is another factor involved in these decompositions, namely, the ease with which the acid loses carbon dioxide when heated. This is a very important factor, and the relative quantities of the products of the decomposition are largely dependent upon this factor. Of the acids thus far investigated, dimethyl- and diethylaceto-acetic acid and benzoylacetic acid might be mentioned. These acids were all selected because of their similarity, since all are substituted acetic acids, and lose carbon dioxide very readily. As anticipated, the mercuric salts of dimethyl- and diethylaceto-acetic acids when thoroughly dried and heated in a vacuum at 90° split off carbon dioxide, and the mercury became attached to the carbons originally bound to the carboxyl groups. This type of decomposition is illustrated below by that of the mercuric salt of

diethylaceto-acetic acid:  $[CH_3CO.C(C_2H_5)_2.CO_2]_2Hg \xrightarrow{\text{Heat}} 2CO_2 + [CH_3-CO.C(C_2H_5)_2-]_2Hg$ .

In the case of benzoylacetic acid, which contains two labile  $\alpha$  hydrogen atoms, the reaction may be made to go in either of two directions which depend upon the conditions under which the experiment is carried out. When the acid is heated with mercuric oxide in alcohol, carbon dioxide is evolved, and mercury-bis-benzoylmethane is obtained. If the reaction is carried out in chloroform, no carbon dioxide is lost, the mercury going to the  $\alpha$  carbon atom. The two processes may be illustrated by the following equations.

$$(C_6H_5COCH_2CO_2)_2Hg \xrightarrow{\text{heated}} 2CO_2 + (C_6H_5COCH_2)_2Hg$$

$$C_6H_5COCH-CO + C_6H_5COCH_2CO_2H$$

$$C_6H_5COCH-CO + C_6H_5COCH_2CO_2H$$

$$Hg-O$$

In the methylated and ethylated aceto-acetic acids, where the labile  $\alpha$  hydrogen atoms are replaced by alkyl groups, only the tendency to split off carbon dioxide was observed.

In the case of the acids previously mentioned where, upon heating the mercury salts, the mercury takes the place originally held by the carboxyl group, there is also a great tendency for the mercury to split out and link the two carbons. This usually takes place at temperatures slightly higher than those at which the decomposition of the mercury salt into the mercury-bis compound occurs although some compounds such as mercury-

13 The experimental data are not recorded in this paper, for the position of the mercury in the ring has not been definitely established, but will be reported in a later paper.

bis-acetodiethyl methane and the corresponding dimethyl compound lose mercury spontaneously when kept for a few days. Again, in the case of the mercuric salt of phthalide carboxylic acid, we were not able to isolate the intermediate mercury compound, the salt decomposing when heated into carbon dioxide, metallic mercury and dihydrophthalide. 14,15

CH—CO₂ heat 
$$(C_0H_4 O)_2Hg \xrightarrow{heat} Hg + 2CO_2 + C_0H_4 O O C_0H_4$$

Similar linking undoubtedly took place when the mercuric salts of diethyland dimethylaceto-acetic acids were distilled in a vacuum. The isolation of these ketones, and a thorough study of the linking of the carbon to carbon by means of these mercury derivatives will be continued by Kharasch and Mildred W. Grafflin.

Mercury carbon compounds differ very widely in their stability toward various reagents such as sodium hydroxide and ammonium sulfide. If we neglect, for the time being, the aromatic mercuri-organic derivatives, which will be discussed in greater detail in a paper by Kharasch and Chalkley, we may consider the mercury aliphatic compounds to be of the

¹⁴ An exceedingly interesting reaction takes place when the mercuric salt of phthalide carboxylic acid is treated with sodium hydroxide; metallic mercury separates and from the solution two acids can be isolated; phthalide carboxylic acid and its oxidation product phthalonic acid. It appears, thus, that in alkaline solution one-half of the phthalide carboxylic acid is oxidized to phthalonic acid, leading thus to the products isolated.

CH—CO₂

$$(C_6H_4 O )_2Hg + 3NaOH \longrightarrow Hg + 2H_2O + C_6H_4 O + C_6H_4$$

$$CO CO_2Na$$

$$CO CO_2Na$$

This rather striking behavior is very readily comprehended since phthalide carboxylic acid is a  $\gamma$  lactone, which we should expect to be quite susceptible to oxidation.

¹⁵ The chemistry of the decomposition of the keto carboxylic acid when heated will be reported by one of us in connection with the photochemical decomposition of mercuric salts of other keto acids, such as pyruvic acid.

¹⁶ The speed of reaction of bridged mercury compounds with mercuric chloride is also of great significance in regard to the stability of the mercury-carbon union in the bridged compounds. Mercury-bis-acetodiethyl and -dimethyl methane react almost instantly with mercuric chloride, in the following manner:  $[H_3C.CO.C(C_2H_5)_2-]_2$ -Hg + HgCl₂  $\longrightarrow$  H₃C.CO.C(C₂H₅).HgCl. The reaction of mercury-bis-acetodiethyl methane and mercuric chloride is taken for illustration. These compounds constitute the first definite mercury compounds of an alkylated acetone in which it is quite certain that the mercury is attached to a carbon atom. Some of the products of acetone, and substituted acetones, described in the literature are simply mixtures of various compounds, and there is absolutely no ground for assigning to a compound a formula such as the following:  $5(Me)_2CO.8HgSO_4.12HgO$  [Denigès, Ann. chim. phys. [8] 12, 401 (1907)]. It is merely an attempt on the part of the investigator to fit his analytical figures to a formula.

same kind as the inorganic compounds, but differing from them in being less ionized. Naturally, it is the degree of ionization of these derivatives that determines whether a compound will give a test with sodium hydroxide or ammonium sulfide. It is understood, of course, that the degree of ionization of the mercury from the carbon is a function of the constitution of the molecule. Thus, while mercuric chloride, a representative inorganic compound, gives an immediate precipitate of mercuric oxide when treated with sodium hydroxide, mercuric cyanide does not. Ammonium sulfide, however, precipitates mercuric sulfide from both substances, on account of the extraordinary insolubility of mercuric sulfide. Similarly, the mercury derivatives of substituted acetones, the bridged as well as the unbridged, do not give a test for mercuric ions with sodium hydroxide, but ammonium sulfide gives an immediate precipitate of mercuric sulfide. It is noteworthy in this connection that mercuric evanide and the bridged compounds, prepared from substituted acetoacetic acid, react very readily with mercuric chloride. Thus, soon after the solutions were mixed, sodium hydroxide failed in either case to give a test for mercuric ions. The reactions of these aliphatic mercury compounds thus parallel those of mercuric cyanide.

The decomposition of mercuric cyanide into metallic mercury and cyanogen when heated is also of great significance in this connection. It is merely an intramolecular oxidation-reduction reaction between the mercury and the carbon, and is thus quite similar to the decompositions which the aliphatic bridged mercury compounds, previously discussed, undergo when heated. The analogy in chemical behavior of mercuric cyanide and the bridged mercury aliphatic compounds indicates quite strongly that the former has a nitrile and not an isocyanide structure. This view also seems to be in accord with other facts known about mercuric cyanide. The notion certainly deserves consideration, in view of the facts advanced for its support, and will be more thoroughly discussed later.

The investigations along the various lines outlined in the paper are being continued at the University of Maryland.

# Experimental Part

Mercury-bis-benzoylmethane,  $(C_6H_6COCH_2)_2Hg$ .—To 1.3 g. of benzoylacetic acid dissolved in 50 cc. of 95% alcohol, 5 g. of yellow mercuric oxide was added. The whole was then heated to boiling, and filtered. The residue was boiled with 20 cc. of alcohol and filtered. The two filtrates were combined, diluted with water, and cooled in an icebath. A faintly yellow precipitate separated which was washed with water and dried on a porous plate; m. p., 159.5°; yield, 0.8 g.

Analysis.  17  Subs., 0.2624: HgS, 0.1386. Calc. for  $C_{16}H_{14}O_{2}Hg$ : Hg, 45.72. Found: 45.56.

The compound is white. It is soluble in hot alcohol and crystallizes as the solution cools. It is soluble in acetone but insoluble in water or ether.

¹⁷ Unless otherwise indicated all samples for analysis were dried to constant weight in a vacuum over sulfuric acid.

An alcoholic solution of the compound does not give mercuric oxide when treated with sodium hydroxide; however, ammonium sulfide gives an immediate precipitate of mercuric sulfide.

When mercury-bis-benzoylmethane is treated with mercuric chloride it forms the compound described immediately below.

Benzoylmethyl-mercuric Chloride,  $C_6H_5COCH_2HgCl$ .—To 0.32 g. of mercury-bis-benzoylmethane, dissolved in 10 cc. of hot 95% alcohol, 0.2 g. of mercuric chloride was added, and the mixture heated on the water-bath until it no longer gave a test for mercuric ion when sodium hydroxide was added. It was then diluted with water and cooled in ice. The precipitate was collected on a filter, washed with water, and dried on a porous plate; m. p.,  $146^\circ$ ; yield, 0.3 g. The compound thus obtained was found to be identical with that prepared by direct mercuration of acetophenone, the constitution of which has been definitely established as benzoylmethyl-mercuric chloride (phenacylmercuric chloride).

Anhydro- $\alpha$ -hydroxy-mercuribenzoyl Acetic Acid, C₀H₃CO—CH—CO—O—Hg.—

An excess of yellow mercuric oxide was added to 3 g. of benzoyl-acetic acid dissolved in 50 cc. of chloroform. The mixture was kept at the boiling temperature of chloroform for a minute and then filtered. When the filtrate was evaporated to dryness a white solid remained. To remove unchanged benzoylacetic acid, the product obtained above was extracted twice with ether. It was then dried in a vacuum over sulfuric acid; yield, 1.3 g.

Analysis. Subs., 0.4706: HgS, 0.3027. Calc. for  $C_0H_6O_3Hg$ : Hg, 55.32. Found: 55.47.

The compound is white. It is slightly soluble in cold chloroform, very soluble in hot, and insoluble in ether; it is insoluble in water, but readily soluble in sodium hydroxide. The compound decomposes at about 290°. When treated with dil. hydrochloric acid, benzoylacetic acid and mercuric chloride are formed. The compound does not give an immediate violet coloration with an alcoholic ferric chloride solution but, if it is first acidified with hydrochloric acid, an immediate violet coloration characteristic of benzoylacetic acid is obtained.

Mercuric Phthalide-Carboxylate, (CoH4COOCHCOO)2Hg.—To 1 g. of phthalide

carboxylic acid, dissolved in 200 cc. of hot water, 0.89 g. of mercuric acetate, dissolved in a small amount of water, was added. A heavy white precipitate was obtained which was collected on a filter, washed with cold water and then with a small amount of alcohol and ether. It melted, with decomposition, at 195°.

Analyses. Subs., 0.3277, 0.5667, 0.4674: HgS, 0.1380, 0.2336, 0.1942. Calc. for  $C_{18}H_{10}O_{3}Hg$ : Hg, 36.16. Found: 36.32, 35.55, 35.83.

The compound is easily soluble in hot acetone and insoluble in cold alcohol and ether. When it is treated with sodium hydroxide, metallic mercury separates.

## Action of Sodium Hydroxide on the Mercuric Salt of Phthalide Carboxylic Acid

To 5 g. of mercuric phthalide carboxylate 10 cc. of sodium hydroxide (6 N) was added. An immediate precipitation of metallic mercury took place. The mixture was filtered and the filtrate shaken with charcoal, to remove traces of finely divided mercury, and then filtered again. After that, the filtrate did not contain any mercury. It was acidified with dil. sulfuric acid and extracted several times with ether. On evaporation of the ether an oil was obtained which solidified after standing for some time. The compound was easily soluble in water; m. p.,  $100^{\circ}$ ; yield, 1.2 g. The compound thus

obtained was extracted with chloroform and the insoluble portion was treated with a very small amount of water and allowed to crystallize slowly, after which the crystals were again extracted with chloroform. The residue dried on a porous plate, melted at 140°. Phthalonic acid prepared by the oxidation of naphthalene melted at 145°, and a mixture of the phthalonic acid with the above product melted at 140°. Both products gave a red coloration when treated with coned. sulfuric acid and benzene containing thiophene.

The chloroform filtrates were combined, evaporated to dryness, and the solid residue was extracted twice with small amounts of water. The residue was dried on a porous plate. This product melted at 144.5°. Phthalide carboxylic acid prepared by reducing phthalonic acid melted at 151°, and a mixture of the two melted at 150°. This product gave only a faint pink coloration with concd. sulfuric acid and benzene containing thiophene.

When mercuric-phthalide carboxylate is heated to 195°, it melts and decomposes, metallic mercury separates and the compound described immediately below is formed.

## Preparation of Dihydrophthalide from the Mercuric Salt of Phthalide Carboxylic Acid

One g. of the well-dried mercuric salt of phthalide carboxylic acid was heated to 195° when it decomposed with the separation of metallic mercury. When cold the solid was extracted with hot glacial acetic acid. As the filtrate was cooled, a yellow solid separated which was collected on a filter and washed with water. The product was then dried in a vacuum over sulfuric acid; m. p., 250°; yield, 0.36 g.

Pure dihydrophthalide prepared from phthalic anhydride, mixed with this compound was found not to depress the melting point.

Mercurous Benzoylformate,  $C_6H_6CO.CO_2Hg.$ —Benzoylformic acid was dissolved in 175 cc. of 80% alcohol, and 40 g. of yellow mercuric oxide was added. The mixture was boiled for a few minutes and filtered. As the filtrate cooled, a white precipitate separated which was collected on a filter.

Analysis. Subs., 0.1597: HgS, 0.1063. Calc. for C₈H₅O₅Hg: Hg, 57.40. Found: 57.45.

The compound is white. When it is treated with sodium carbonate or sodium hydroxide, metallic mercury separates. The same observation was made when pyridine was used as a solvent for the compound. This is characteristic of mercurous salts. The compound is only slightly soluble in boiling alcohol. When acidified with dil. sulfuric acid and extracted with ether, the ether extract upon evaporation gave a white solid which melted at 57°. Benzoylformic acid melts at 62° and was found not to depress the melting point of this compound. When the substance was heated the odor of benzaldehyde was noticeable.

Mercuric Benzoylformate, (C₆H₅CO.CO₂)₂Hg.—To 12.6 g. of benzoylformic acid dissolved in 500 cc. of water, a solution of 13.4 g. of mercuric acetate in 100 cc. of water was added slowly and the mixture was constantly stirred. A white precipitate was obtained which was collected on a filter and washed with water; m. p., 164°; yield, 15 g.

Analysis. Subs., 0.1779: HgS, 0.0867. Calc. for  $C_{16}H_{10}O_6Hg$ : Hg. 40.23. Found: 42.03.

The compound is white. It is soluble in pyridine and nitrobenzene, but only slightly soluble in water. When it was heated to 180° mercury separated, carbon dioxide was evolved and benzoic acid was formed. After it had been refluxed in nitrobenzene, a solid was obtained which had no definite melting point but decomposed at about 200°, and when treated with sodium hydroxide or pyridine metallic mercury separated from it. This is characteristic of mercurous salts.

Mercuric- $\alpha$ , $\alpha$ -diethyl-aceto-acetate, [CH₃CO.C(C₂H₅)₂.CO₂]₂Hg.—To 8.5 g. of  $\alpha$ , $\alpha$ -diethyl-aceto-acetic acid, dissolved in 50 cc. of 30% alcohol, 9.2 g. of mercuric acetate, dissolved in a small amount of water, was slowly added and the mixture constantly stirred. The precipitate was collected on a filter, washed with water and then with a small amount of alcohol. The product thus obtained melted at 103° with decomposition; yield, 7 g.

Analysis. Subs., 0.1649: HgS, 0.0754. Calc. for  $C_{16}H_{26}O_{6}Hg$ : Hg, 38.97. Found: 39.43.

The compound is easily soluble in pyridine and hot alcohol. It is not very soluble in ether or cold nitrobenzene but dissolves in hot nitrobenzene, metallic mercury separating at the same time. When the compound is heated to its melting point carbon dioxide is evolved and the product described immediately below is formed.

Mercury-bis-aceto-diethylmethane,  $(CH_3CO.C(C_2H_5)_2-)_2Hg$ .—When mercuric- $\alpha$ ,  $\alpha$ -diethyl-aceto-acetate was heated in a vacuum to 85°, the compound melted, carbon dioxide was evolved and later the melt solidified. When the loss in weight corresponded to two molecular equivalents of carbon dioxide, the reaction was considered complete. The solid was then dissolved in acetone and the solution filtered. Upon slow evaporation of the solvent, a white solid separated which was dried on a porous plate. It melted at  $109^{\circ}$  with decomposition. The yield was almost quantitative.

For analysis the compound was dried as quickly as possible in a vacuum over phosphorus pentoxide.

Analysis. Subs., 0.1319: HgS, 0.0736. Calc. for  $C_{14}H_{26}O_2Hg$ : Hg, 47.00. Found: 48.11.

The compound is soluble in acetone, chloroform and benzene, but insoluble in water. It is unstable and decomposes rapidly, with the separation of metallic mercury, into an oil which has an odor somewhat resembling that of camphor. This instability explains the high value obtained for mercury. When an alcoholic solution of the compound was treated with ammonium sulfide a precipitate of mercuric sulfide was formed immediately.

When this substance is treated with mercuric chloride, the compound described immediately below is formed.

Aceto-diethyl-methyl-mercuric Chloride,  $(CH_3CO.C(C_2H_3)_2-)HgCl.-To$  1.75 g. of mercury-bis-aceto-diethylmethane dissolved in 15 cc. of 95% alcohol was added a solution of 1.12 g. of mercuric chloride in 30 cc. of warm alcohol. The solution was cooled in a freezing mixture, and a white solid separated; m. p., 77°; yield, 0.85 g.

Analysis. Subs., 0.3618: HgS, 0.2408. Calc. for  $C_7H_{13}$ OClHg; Hg, 57.44. Found: 57.40.

The compound crystallizes slowly from alcohol. In the above preparation, shortly after the mercuric chloride was added to the mercury-bis-aceto-diethylmethane, no mercuric ions could be detected by the addition of sodium hydroxide. The compound gave, however, an immediate precipitate of mercuric sulfide with ammonium sulfide.

Mercuric Dimethyl-aceto-acetate,  $[CH_2CO.C(CH_8)_2.CO_2]_2Hg.$ —To 40 g. of mercuric acetate dissolved in 150 cc. of water was slowly added 29 g. of  $\alpha,\alpha$ -dimethylaceto-acetic acid, dissolved in 100 cc. of 30% alcohol. A thick paste formed immediately. More water was then added and the mixture was well stirred; the precipitate was collected on a filter and washed well with water. When dried on a porous plate the compound melted at 100°, with decomposition; yield, 15.5 g.

Analysis. Subs., 0.4237: HgS, 0.2206. Calc. for C₁₂H₁₈O₆Hg: Hg, 43.74. Found: 44.80.

The compound is white and is insoluble in water. When heated to 100°, it melts with decomposition, carbon dioxide is evolved and metallic mercury separates. With

sodium hydroxide a yellow precipitate of mercuric oxide is obtained. When it is heated to 90° in a vacuum, the product does not melt but carbon dioxide is evolved and the compound described immediately below is formed.

Mercury-bis-aceto-dimethyl-methane,  $[CH_3CO.C(CH_3)_2-]_2Hg.$ —When mercuric  $\alpha,\alpha$ -dimethyl-aceto-acetate was heated in a vacuum at 90° it lost two molecular equivalents of carbon dioxide as indicated by an equivalent loss in weight. The solid was then extracted with acetone at room temperature and the acetone evaporated in a vacuum over sulfuric acid. A white solid remained which melted at 120° with decomposition. The yield was almost quantitative.

For analysis the compound was dried as rapidly as possible in a vacuum over phosphorus pentoxide.

Analysis. Subs., 0.3355: HgS, 0.2094. Calc. for  $C_{10}H_{18}O_2Hg$ : Hg, 54.11. Found: 53.83.

The compound is soluble in acetone and alcohol, and very slightly soluble in ether. It may be crystallized from toluene or xylene. No mercuric oxide formed upon the addition of sodium hydroxide, but upon the addition of ammonium sulfide an immediate precipitate of mercuric sulfide was obtained. The compound is unstable and rapidly decomposes with the separation of metallic mercury. When the compound (5 g.) was distilled in a vacuum at 90°, 1.3 g. of an oil was obtained which gave only a faint test for mercury and had an odor resembling that of camphor.

When mercury-bis-aceto-dimethyl-methane is treated with mercuric chloride the product described below is formed.

Aceto-dimethyl-methyl-mercuric Chloride, CH₃CO.C(CH₃)₂—HgCl.—A solution of 1.4 g. of mercuric chloride dissolved in 30 cc. of 95% alcohol was added to 1.8 g. of mercury-bis-aceto-dimethyl-methane in 15 cc. of alcohol. The mixture was refluxed for five minutes. As it cooled, beautiful white crystals with a metallic luster separated; m. p., 124.5°; yield, 1.1 g.

Analyses. Subs., 0.3127, 0.2934: HgS, 0.2229, 0.2116. Calc. for  $C_6H_9OClHg$ : Hg, 62.49. Found: 61.48, 62.20.

The compound is soluble in hot alcohol. When treated with sodium hydroxide it does not give a precipitate of mercuric oxide, but ammonium sulfide gives an immediate precipitate of mercuric sulfide.

Mercuric Trimethylacetate, [(CH₃)₃C.CO₂]₂Hg.—Trimethylacetic acid was dissolved in sodium hydroxide and the calculated amount of mercuric nitrate was added. A yellow product separated which was purified by crystallization from hot chloroform. Long, beautiful white needles were thus obtained which melted at 235°. The yield was good.

Analysis. Subs., 0.2855: HgS, 0.1629. Calc. for  $C_{10}H_{18}O_4Hg$ : HgS, 49.81. Found: 49.21.

The compound is soluble in hot chloroform and pyridine, but is very slightly soluble in carbon tetrachloride. When it was boiled in nitrobenzene, the color of the solution gradually became darker and metallic mercury separated. When it was heated to 240° in a vacuum, there was no evolution of carbon dioxide.

#### The Action of Mercuric Oxide on Trichloro-acetic Acid

1. Freshly distilled trichloro-acetic acid was dissolved in water and treated with an excess of yellow mercuric oxide and the solution filtered. When the filtrate was allowed to stand at room temperature (or concentrated in a vacuum) a mercurous salt was formed, as proved by the fact that it gave a precipitate of metallic mercury when treated with sodium hydroxide or pyridine. This mercurous salt is mercurous chloride, as is shown by the following analysis.

Analysis. Subs., 0.6908: HgS, 0.6647. Calc. for HgCl: Hg, 84.96. Found: 82.99.

When the filtrate from trichloro-acetic acid and mercuric oxide was heated to  $60-65^{\circ}$ , mercurous chloride precipitated and the acidity of the solution increased and reached a constant value after 30 minutes; at the end of that time all of the mercuric salt originally present had been converted into mercurous chloride.

2. A chloroform solution of freshly distilled trichloro-acetic acid was treated with yellow mercuric oxide containing a little water and the insoluble portion collected on a filter. The filtrate upon evaporation gave a white solid which was identified as mercuric chloride. Mercurous chloride was identified as part of the insoluble portion.

### Summary and Conclusions

- 1. The behavior of mercury salts of various aliphatic carboxylic acids which do not lose carbon dioxide when heated has been studied. In cases where there is a replaceable hydrogen on the  $\alpha$  carbon atom, the mercury usually takes that position, giving an inner anhydride.
- 2. The abnormal behavior of the mercury salt of trichloro-acetic acid has been pointed out.
- 3. In the case of the mercury salts of phenylated acetic acids the velocity of mercuration in the benzene nucleus was found to be greater than that of the  $\alpha$  carbon atom—so that in working with 15- or 20g. lots, no side chain substitution products could be isolated.
- 4. In the case of mercury salts of substituted aliphatic acids which split off carbon dioxide readily, the mercury usually takes the place previously occupied by the carboxyl groups, thus linking the two molecules. (See the behavior of benzoylacetic acid for the possibilities of side reactions.)
- 5. The substituted mercury acetone derivatives, the bridged as well as unbridged, do not react with sodium hydroxide, but give an immediate precipitate of mercuric sulfide when treated with ammonium sulfide. Their behavior is similar to that of mercuric cyanide.
- 6. It is pointed out that the evidence is more in favor of a nitrile structure for mercuric cyanide than an isocyanide structure.
- 7. The linking of carbon to carbon through the intermediate mercuribis compounds is discussed, and the formation of dihydrophthalide from mercuric-phthalide-carboxylate is considered in the light that it is merely a case of intramolecular oxidation-reduction in which the mercury acts as the oxidizing agent.
- 8. The oxidation of a  $\gamma$  lactone to a ketonic acid by the use of mercuric oxide in alkaline solution has been observed.
- 9. The preparation of the following new compounds is described: mercury-bis-benzoylmethane; anhydro- $\alpha$ -hydroxymercuri-benzoyl-acetic acid; mercuric phthalide-carboxylate; mercurous benzoylformate; mercuric benzoylformate; mercuric  $\alpha,\alpha$ -diethyl-aceto-acetate; mercury-bis-aceto-diethylmethane; aceto-diethyl-methyl-mercuric chloride; mercuric  $\alpha,\alpha$ -

dimethyl-aceto-acetate; mercury-bis-aceto-dimethylmethane; aceto-dimethyl-methyl-mercuric chloride; mercuric trimethylacetate.

# NEW METHODS OF SPLITTING PYRIMIDINES. II. THE DECOMPOSITION OF PYRIMIDINES BY MEANS OF FERROUS SALTS

By Mimosa Hortense Pfaltz¹ and Oskar Baudisch Received February 1, 1923

The reactions which we have used in splitting pyrimidines take place under conditions resembling as closely as possible natural conditions in the metabolism of plants and animals. Two methods have been studied intensively, namely, the system, ferrous sulfate plus sodium bicarbonate plus air, and the system, sodium pentacyano-aquo-ferroate,  2  [Fe  $^{\rm II}(\rm CN)_5\rm OH_2$ ]Na3, plus oxygen or air. In both cases the reactions were carried out at room temperature (primary process), while the complete hydrolysis of the intermediate products (secondary process) was brought about at blood-temperature or at the temperature of the water-bath.

These methods, which were introduced by Baudisch,³ will be applied to other types of compounds. The use of the system, ferrous sulfate plus sodium bicarbonate plus air, in a very sensitive test for thymine has already been described.⁴

Ferrous salts, which have been used previously only as reducing agents, under suitable conditions exert a strong hydrolyzing and oxidizing action on certain types of compounds. The reactions in the cases which have already been studied are quite similar to the hydrolytic changes brought about by life processes or by light energy. Under mild conditions it is possible to cause a partial hydrolysis of the stable pyrimidine ring with the formation of substances which are completely hydrolyzed by sodium bicarbonate at temperatures between 37° and 80°.

# The Action of Ferrous Sulfate Plus Sodium Bicarbonate Plus Air on Pyrimidines

When ferrous sulfate is added to an aqueous solution of uracil containing an excess of sodium bicarbonate, a green ferrous carbonate peroxide is precipitated. When the reaction mixture is shaken with air, the ferrous compound is oxidized gradually to ferric hydroxide, while the pyrimidine

- ¹ This paper is constructed from a dissertation presented by Mimosa Hortense Pfaltz to the Faculty of the Graduate School of Yale University in candidacy for the degree of Doctor of Philosophy. (O. B.)

  - ³ Baudisch, Ber., 54, 406 (1921).

Johnson and Baudisch, This Journal, 43, 2670 (1921); Ber., 55, 18 (1922).

suffers a partial hydrolysis with the formation of an intermediate compound. When the filtered solution, which contains excess sodium bicarbonate, is warmed this intermediate compound is completely hydrolyzed to urea and other products. When thymine is used instead of uracil, we obtain urea, acetol and pyruvic acid.

The amount of bicarbonate in the solution affects the extent of the hydrolysis.

# Table I Influence of Bicarbonate and Evaporation

In each experiment 2.0 g. of uracil, 30 g. of FeSO₄.7 $\rm H_2O$ , and 700 cc. of distilled water were used. The reaction mixture, after the addition of solid NaHCO₂, was shaken with air in a flask.

Weight of NaHCOs		% Urea formed		
G.	Molecular equivalents	Without evaporation	With evaporation

54	6		$7.43^{a}$	
108	12 .	traces	12.1	

^a The numerical values for urea do not take into account the slight hydrolysis produced by the distillation with sodium bicarbonate.

# The Action of Sodium Pentacyano-aquo-ferroate Plus Oxygen or Air on Pyrimidines

The system, sodium pentacyano-aquo-ferroate² ("aquo salt")⁵ plus oxygen or air, also brings about a partial hydrolysis of the pyrimidine ring. Four-tenths g. of uracil and 1.00 g. of the complex salt were dissolved in distilled water and a stream of oxygen gas was passed through the solution for 16 hours. Urea could not be detected in the reaction mixture, even after it was warmed on the water-bath. However, after the addition of sodium bicarbonate and evaporation, a quantity of urea was found which corresponded to a split of 6.43%.

The quantity of uracil split can be increased by shaking the dark green solution of uracil and aquo salt with oxygen under a pressure slightly greater than one atmosphere.

Table II

Influence of "Activation" and Oxygen Pressure
In each experiment 0.200 g, of uracil and 0.60 g, of aquo salt were used.

No.	Conditions	Urea formed
1	Uracil with stream of oxygen for 22 hours	18.3
2	"Activated uracil" with stream of oxygen for 22 hours	15.5
3	"Activated uracil" shaken with oxygen under pressure for 10	
	hours	53.0

Evidence will be submitted below for the assumption that a loose compound is formed by uracil and aquo salt, the presence of this compound

^{5 &}quot;Aquo salt" is used for convenience as an abbreviation for sodium pentacyanoaquo-ferroate.

being indicated by a strong green color; when present in this compound, uracil may be said to be activated. In Expt. 3, oxygen displaces the uracil more readily from the compound because of the greater pressure. This oxygen enters the inner sphere of the complex salt and thus becomes activated with the result that it is able to react with activated uracil.

The largest splits are obtained when a freshly prepared solution of aquo salt and uracil is shaken with oxygen under slight pressure. Under these conditions amounts of urea up to 57% of that calculated were found.

It should be emphasized that the presence of ferrous salts is necessary to bring about a decomposition of pyrimidines by the action of molecular oxygen under ordinary conditions. This fact was proved by experiments in which oxygen was passed through aqueous solutions of uracil and thymine for 22 hours. Solid sodium bicarbonate was then added and the solutions were evaporated to dryness. By careful tests with xanthydrol it was impossible to detect any trace of urea.

## The Action of Ferrous Sulfate Plus Oxygen and of Ferrous Sulfate Plus Hydrogen Peroxide on Pyrimidines

If oxygen is passed through a solution of uracil or thymine containing ferrous sulfate, only a small split results. The extent of the split is slightly greater if hydrogen peroxide is substituted for oxygen. As stated above, the presence of a ferrous salt is necessary for the decomposition when molecular oxygen is used.

#### TABLE III

Comparison of Activation of Oxygen by Simple and Complex Iron Salts

In each experiment 0.200 g. of pyrimidine and an equimolecular quantity of the ferrous salt were used. The uracil solutions were shaken 11.5 hours with oxygen under pressure and the thymine solutions 24 hours.

Reagent	Urea formed	Urea formed
Oxygen	. 0	0
Aquo salt + oxygen	. 40.9	13.1
$FeSO_4.7H_2O + H_2O_2$	. 4.3	3.5
FeSO _{4.7H₂O + oxygen}	. 2.9	2.0

# Evidence of Compound Formation between Complex Ferrous Ions and Pyrimidines

An explanation of the action of aquo salt as a catalyst in the reactions which have been discussed can best be given by considering the process in the light of Werner's Coördination Theory.

- ⁶ An aqueous solution of aquo salt is light yellow in color, while an aqueous solution of uracil is colorless.
- ⁷ It has been shown by Bass, however, that oxygen is able to split thymine to some extent under the influence of light, even in the absence of ferrous salts. L. W. Bass, This Journal, 1924.

It has been shown that sodium pentacyano-aquo-ferroate can form compounds in which aquo (water molecule) has been replaced by whole organic molecules, such as pyridine, nitrosobenzene, p-nitrosodimethylaniline, etc.

Most of these "penetration compounds" are characterized by their striking colors. For example, in the reaction given above the light yellow color of the aquo salt changes to deep violet. The nitrosobenzene can be displaced from this violet compound by other substances which have a stronger affinity for the iron nucleus, such as sodium nitrite, sodium cyanide and carbon monoxide. In other words, we have to do with a competition for the auxiliary valences of the complex nucleus.

By analogy we are led to the conclusion that the pyrimidines, also, in the reaction with aquo salt primarily become linked to the central iron atom by displacing the water molecule. This conclusion is justified by the striking color changes which take place when a pyrimidine is allowed to react with aquo salt in the absence of air. Uracil and thymine form dark green compounds, while cytosine yields a deep red compound.

As a result of this compound formation the pyrimidine becomes "activated" and is therefore more susceptible to hydrolysis and oxidation. Similarly, oxygen becomes "activated" by other molecules of the complex salt.

While we have definite evidence, in the case which has just been discussed, of the dependence of the reaction upon the auxiliary valences of the iron nucleus, we have no conclusive proof that penetration compounds containing pyrimidines are formed by ferrous carbonate or its peroxide. In this case, however, it was proved indirectly that addition of the pyrimidine to ferrous ion precedes the reaction; hence, we believe that this reaction also is dependent upon the action of auxiliary valences.

If caustic alkali is used in place of the weakly alkaline bicarbonate, the freshly precipitated ferrous hydroxide is able to absorb and activate atmospheric oxygen, but the pyrimidine present is not split under these conditions because the sensitive auxiliary valences of the ferrous ions are already occupied by sodium hydroxide molecules which the pyrimidine is unable to displace. If more alkali is used, even the absorption of oxygen

⁸ Manchot and Woringer, Ber., 46, 3519 (1913).

⁹ Ref. 3, p. 414.

¹⁰ Schwarz-Bass, "The Chemistry of the Inorganic Complex Compounds," John Wiley and Sons, New York, 1923, p. 30.

is prevented,¹¹ that is, the precipitate of ferrous hydroxide remains white even when oxygen is passed through the reaction mixture.

Additional proof of the assumption that the reaction depends upon the action of auxiliary valences has been brought forward by Bass, 12 who has shown that the catalytic decomposition of pyrimidines by the system, ferrous sulfate plus sodium bicarbonate plus air, may be poisoned by adding small quantities of arsenic trioxide, potassium nitrite, or ammonia to the reaction mixture.

#### Methods of Retarding the Reaction

The hydrolytic split of pyrimidines by aquo salt plus oxygen can be retarded in two ways. First, substances can be added to the reaction mixture which have a strong affinity for iron and which, therefore, occupy the auxiliary valences of the iron nucleus (poisoning). Second, the pyrimidine ring can be transformed into a more saturated condition, thus retarding or even preventing the formation of a complex compound with the ferrous salt.

In the first case the reaction may be retarded by adding potassium cyanide to the reaction mixture in an amount equivalent to the aquo salt and by allowing the solution to stand for a few minutes before passing in oxygen. When a solution of 0.200 g. of uracil and 0.60 g. of aquo salt was treated with oxygen for 22 hours, a quantity of urea equivalent to a split of 18.3% was obtained. In a duplicate experiment with an equimolecular quantity of potassium cyanide (0.155 g.), only 2.05% of urea was formed. Ammonia may be used in place of potassium cyanide. In an experiment with sodium pentacyano-ammine-ferroate, [Fe^{II}(CN)₅NH₃]-Na₃, uracil was not attacked, while a duplicate experiment with aquo salt gave a split of 9.7%.

When uracil, in complete absence of air, is shaken with aquo salt, we obtain the deep green solution mentioned previously, which has been shown to contain a complex compound of uracil and aquo salt. If oxygen is passed through this solution, only a small quantity of urea is formed, a fact which indicates that oxygen is not activated by the complex compound.

The second method of retarding the reaction, saturation of the pyrimidine ring, is best illustrated by comparing the extent of the split in uracil and hydro-uracil. In each experiment we used  $0.200~\rm g$ . of pyrimidine with an equimolecular quantity of aquo salt, the solution being shaken with oxygen under pressure for 9 hours. Under these conditions uracil gave 31.9% of urea and hydro-uracil 12.3%. From these results it is seen that saturation of the double bond in uracil decreases the extent of the split.

¹¹ Baudisch and Mayer, Biochem. Z., 107, 1 (1920).

¹² Bass, unpublished researches.

# The Influence of the Methyl Group on the Stability of the Pyrimidine Ring

The influence of the methyl group on the stability of the pyrimidine ring under the conditions which we have described is illustrated by the following results. In experiments using 0.200 g. of pyrimidine, an equimolecular quantity of aquo salt, and oxygen under pressure, the following splits were obtained: uracil, 31.9%; thymine, 14.7%; and 4-methyluracil, 55.6%.

It has been shown by Biltz¹³ that in alkaline solution carbon atom 5 of alloxan has a strong affinity for one of the nitrogen atoms of the urea residue and that under suitable conditions alloxanic acid is formed.

This property can undoubtedly be shared by other pyrimidines and explains the fact that thymine is more stable than uracil or 4-methyluracil. In thymine a methyl group is linked to the sensitive carbon atom in Position 5, with the result that any reactions attacking this carbon will be hindered. In 4-methyluracil, on the other hand, the methyl group is attached to a carbon atom which does not have a direct influence on the reaction.

#### Experimental Part

Apparatus.—For the precipitation of ferrous hydroxide in the absence of air an 800cc. Kjeldahl flask was used which was provided with a ground-glass stopper fused to a glass tube ending in a glass stopcock. The same type of flask was used in experiments which were conducted by shaking the reaction mixtures with oxygen under pressure. In experiments which employed a stream of oxygen, small gas wash bottles of about 300 cc. capacity were used.

### Analytical Methods

Urea Determination.—Urea determinations were made in the filtered solutions obtained by dissolving with water the dry residues resulting from the evaporation of the reaction mixtures with sodium bicarbonate. The urea was precipitated according to Fosse's directions for solutions containing from 0.1 g. to 1.0 g. of urea per liter. The proportions are 1 volume of solution, 2 volumes of glacial acetic acid, and 1/20 volume of a 10% solution of xanthydrol in methyl alcohol.

To insure complete precipitation, the solutions were usually allowed to stand overnight. The precipitate was filtered in a Gooch crucible and was washed first with alcohol to remove excess of xanthydrol and then with water until free from acid. After the addition of glacial acetic acid the solutions always turned green when pentacyano salts had been used. This Prussian blue was removed from the precipitates by washing them

¹³ Biltz, Heyne and Bergius, Ann., 413, 68 (1916). Biltz, Ber., 54, 1809 (1921).

¹⁴ Fosse, Ann. chim., [9] 6, 13 (1916).

first with water and then with alcohol. The crucibles were dried at 120° and the dixanthylurea was identified by its melting point (257°).

Acetol Test.—Acetol tests were made on the clear distillates obtained from reaction mixtures of thymine. The test depends upon the formation of 3-hydroxy-quinaldine when acetol is treated with o-aminobenzaldehyde in alkaline solution.¹⁵ This compound shows a strong blue fluorescence, a phenomenon which makes the test very delicate.

The heated distillate from the reaction mixture was treated with 0.01 g. of o-amino-benzaldehyde in alcohol and 5 cc. of sodium hydroxide. Two-thirds of this solution was evaporated by boiling. After cooling, it was acidified with hydrochloric acid and then made alkaline with an excess of solid sodium bicarbonate. A blue fluorescence proved the presence of acetol. If the test obtained was so slight as to be doubtful, some of the solution was poured into a quartz test-tube and illuminated by ultraviolet light from an iron arc. By this means a test was often obtained when the blue fluorescence was not visible in daylight.

Pyruvic Acid Test.—This test was applied to the residues obtained by evaporating thymine reaction mixtures to dryness. It depends upon the formation of indigo when pyruvic acid in alkaline solution is treated with o-nitrobenzaldehyde. 16

After evaporation of the reaction mixture the residue was taken up with water and evaporated again almost to dryness. To this solution were added an aqueous emulsion of o-nitrobenzaldehyde and a small quantity of potassium hydroxide solution.

The mixture was then shaken with chloroform. A deep blue color in the chloroform layer proved the presence of pyruvic acid in the sample.

#### Experiments with Ferrous Carbonate Peroxide

The discussion of the experimental work with ferrous carbonate peroxide will be confined to a complete description of one typical experiment.

Two g. of uracil (Expt. 2, Table I) were dissolved with 54 g. of sodium bicarbonate in 700 cc. of boiling water. This solution was boiled for at least one hour in an 800cc. Kjeldahl flask (as described above) to remove all oxygen dissolved in the water. A test-tube containing 30 g. of powdered ferrous sulfate (FeSO₄.7H₂O) was lowered into the flask and the contents were boiled for 10 minutes longer. The ground-glass stopper, with the stopcock open, was fitted into the neck. When steam began to come out of the open end of the stopper the flame was removed and the stopcock was closed. After the reaction mixture had been cooled to room temperature the flask was inverted so that the alkaline uracil solution came into contact with the ferrous sulfate. A grayish-white precipitate of ferrous carbonate was formed, which slowly hydrolyzed to ferrous hydroxide.

When all of the ferrous sulfate had dissolved, the stopcock was opened to admit air. The precipitate of ferrous hydroxide immediately darkened and then turned green rapidly as the flask was shaken because of the formation of ferrous carbonate (or hydroxide) peroxide. The contents of the flask were then poured into a 2-liter round-bottom flask fitted with a rubber stopper containing a bent glass tube. This flask was shaken by hand until all the ferrous hydroxide peroxide had become oxidized to ferric hydroxide, a process which required about  $1^1/2$  hours.

When the oxidation was completed the reaction mixture was poured into a 1-liter graduated cylinder to allow the precipitate to settle. The clear supernatant liquid began to turn deep red, the color appearing first at the surface and spreading slowly downward through the liquid. After the liquid had stood overnight, the color varied

¹⁵ Baudisch, Biochem. Z., 89, 279 (1918). Compare Ref. 4.

¹⁶ Baeyer, Ber., 15, 2856 (1882). Compare Ref. 4.

from light to dark red, being darkest at the surface. This fact indicated that an absorption of oxygen had taken place, probably by the complex iron salts which exist in the solution.¹⁷

The volume was then made up to 650 cc. and two portions of 50 cc. each were removed by a pipet for determination of urea. One of these portions was evaporated to dryness before the analysis. (For results see Table I.)

#### Experiments with Sodium Pentacyano-aquo-ferroate

In this case, also, only one typical experiment will be described in detail.

One g. of uracil was dissolved in about 400 cc. of boiling water and the solution was then cooled to room temperature and diluted to 500 cc. One hundred cc. of this solution was transferred with a pipet to a Kjeldahl flask (as described above) and diluted with 100 cc. of water. Five-tenths g. of aquo salt (containing 0.08 g. of iron) was then added in the solid form and the flask was evacuated with a suction pump until the golden-brown liquid boiled at room temperature. The stopcock was closed and the flask was connected by means of pressure tubing to a gasometer filled with oxygen under a pressure slightly greater than one atmosphere. The stopcock was opened and the flask was shaken with oxygen for  $7^1/2$  hours. At the end of this time the color had changed to dark reddish-brown.

The reaction mixture was poured into a large evaporating dish and after the addition of 2 g. of sodium bicarbonate was evaporated to dryness on a water-bath. During the evaporation the solution became decolorized and ferric hydroxide was formed. The dry residue was dissolved with water, the solution filtered and diluted to 100 cc. A urea determination was made on half of this solution.

The effect of potassium cyanide is discussed on p. 2976. The reactions were carried out by passing oxygen (from a cylinder) through the solutions instead of shaking them with oxygen under pressure.

In Table II the effect of "activated" uracil is shown. Uracil was activated by boiling it for an hour in a Kjeldahl flask (as described above) with about 700 cc. of water and then lowering the required amount of solid aquo salt into the boiling solution by means of a test-tube. After the solution had boiled for 10 minutes longer the ground-glass stopper, with the stopcock open, was fitted into the flask and boiling was continued until steam came out of the open end of the tube. The burner was then removed and the stopcock closed. After cooling to room temperature the contents of the flask and test-tube were mixed by shaking. In Expt. 2 the reaction mixture was allowed to stand for 43 hours after mixing and in Expt. 3, for 24 hours.

# Experiments with Ferrous Sulfate Plus Oxygen or Hydrogen Peroxide

The experiments with ferrous sulfate plus oxygen were carried out in the same manner as those with aquo salt and oxygen under pressure. When hydrogen peroxide was used instead of oxygen, it was added to the solution last and the flask was shaken with the stopcock open.

On evaporation with sodium bicarbonate, the iron was precipitated as ferroferric oxide, Fe₃O₄, instead of ferric hydroxide. Before evaporation with sodium bicarbonate the iron was already precipitated to some extent as a red ferric salt; the solution itself, however, remained colorless.

The writers wish to acknowledge the helpful suggestions and criticisms of Professor Treat B. Johnson during the progress of this work.

17 Chandra, Dissertation, Berlin, 1913.

#### Summary

- 1. The action of ferrous salts on pyrimidines is described under conditions similar to those found in biological processes.
- 2. The reagents used were: (a) FeSO_{4.7}H₂O + NaHCO₃ + air; (b) [Fe(CN)₅OH₂]Na₃ + O₂ or air; (c) FeSO_{4.7}H₂O + O₂; (d) FeSO_{4.7}H₂O + H₂O₂.
- 3. The cleavage may be considered to take place in two steps: (a) partial hydrolysis and oxidation with the formation of intermediate compounds; (b) complete hydrolysis of the intermediate compounds.

The extent of cleavage is determined by a quantitative estimation of the urea formed. In the case of thymine, acetol and pyruvic acid could be identified as reaction products, a fact which confirms the work of Johnson and Baudisch.⁴

- 4. It was shown experimentally that the reactions described are brought about by means of auxiliary valences of the ferrous compounds and pyrimidines. The proof was obtained by: (a) occupation (poisoning) of the auxiliary valences of the iron nucleus by sodium hydroxide, potassium cyanide, ammonia or pyrimidines; this poisoning in most cases was indicated by accompanying color reactions; (b) hydrogenation of the pyrimidine ring; (c) stabilization of the pyrimidine ring by a methyl group in Position 5.
- 5. The relatively greater efficiency of the complex ferrous salt as compared with an ordinary ferrous salt (FeSO_{4.7}H₂O) has been shown.

### THE OXIDATION OF URIC ACID WITH FERROUS SALTS. I

By Mimosa Hortense Pfai,tz Received February 1, 1923

Introduction.—It was desired to determine the behavior of complex iron salts in the presence of oxygen toward uric acid, the most important member of the purine group. Like the pyrimidines, this compound is of great biological significance, being a product of nuclear metabolism, as well as being further oxidized in the animal body. This oxidation, whatever its nature, takes place under mild conditions (weak alkali and body temperature) and if uric acid could be oxidized in the laboratory under similar conditions, the identification of the products of oxidation might throw some light on the mechanism of uric acid metabolism. With this idea in mind the present investigations were undertaken.

As it has already been shown that pyrimidines can be broken down in the presence of these same complex salts, these investigations were carried out in a manner analogous to those on the pyrimidines.

¹ Pfaltz and Baudisch, This Journal, 45, 2972 (1923).

The Action of Ferrous Sulfate Plus Sodium Bicarbonate Plus Air on Uric Acid.—The system, ferrous sulfate plus sodium bicarbonate plus air, effects a partial decomposition of the purine molecule and it was found as with pyrimidines¹ that it is necessary to heat the oxidized solution on the water-bath before the formation of urea takes place. To a solution of 0.5 g. uric acid in 1000 cc. of water containing 36 g. of sodium bicarbonate (12 molecular equivalents) was added 10 g. of ferrous sulfate and the reaction mixture shaken until the ferrous carbonate peroxide was oxidized to ferric hydroxide. A determination of urea directly after oxidation gave no trace of urea, but after the heating on the water-bath, 29% of urea was formed.

The Action of Sodium Pentacyano-aquo-ferroate Plus Oxygen or Air on Uric Acid.—The experiments for determining the action of the system sodium pentacyano-aquo-ferroate plus oxygen or air were carried out in exactly the same way as those with pyrimidines, with the exception that the uric acid was added to the oxidation mixture as a solid instead of as a solution. As the oxidation proceeds the solution of aquo salt gradually turns red, thereby indicating that a loose combination is formed between the auto-oxidizing agent and the uric acid. This shows that an activation of uric acid takes place, and as it has been shown already that activated oxygen is present in a solution of aquo salt, it is safe to assume here also, that the oxidation is brought about by the interaction of activated oxygen and activated uric acid.

At the same time it was observed that the ammine salt brings about a greater cleavage of uric acid than the aquo salt when both are used under the same conditions. The reason undoubtedly is that the liberated ammonia reacts with the suspended uric acid to form an ammonium salt of uric acid, thereby increasing the concentration of uric acid in solution, thus accelerating the oxidation. These results are indicated by the fact that when 0.100 g. of uric acid and 0.30 g. of auto-oxidizing agent were used, and the solutions oxidized by means of a stream of oxygen for 21 hours, the aquo salt gave a break of 57.7% and an ammine salt of 60.6%.

Very little speculation can be made concerning the mechanism of the reaction between the aquo or ammine salt and uric acid, except the supposition that again an intermediate product is formed before cleavage to urea takes place. However, this intermediate compound is considerably more unstable than the corresponding intermediate product formed when uracil or thymine are oxidized. This is shown by the fact that evaporation of the neutral oxidized mixture brings already a cleavage with a yield of about 50% of urea, while heating after the addition of sodium hydrogen carbonate brings about a yield of urea which is in the neighborhood of 75%.

When 0.100 g. of uric acid and 0.30 g. of aquo salt were subjected to a

² Baudisch, Ber., 54, 413 (1921).

stream of oxygen for 86 hours, direct evaporation of the water gave 46.9% of urea and evaporation in presence of sodium bicarbonate gave 71.5% of urea.

The great susceptibility of the uric acid molecule to the influence of the aquo and ammine salts is shown in two ways. First, uric acid can be extensively oxidized by atmospheric oxygen alone, provided the aquo or ammine salts are used as the auto-oxidizing agents and second, the large yields of urea obtained indicate that the uric acid molecule was more completely decomposed than was the case with the pyrimidines. However, the exact role of the ammine and aquo salt is not known, since the yields of urea are in no way proportional to the amount of salt used.

When 0.75 molecular equivalent of aquo salt is used per equivalent of uric acid (namely 0.30 g. of aquo salt per 0.10 g. of uric acid) all of the uric acid ultimately goes into solution during oxidation, and a yield of approximately 75% of urea is obtained. By increasing the relative amount of auto-oxidizing agent, or by increasing the time of oxidation, it was hoped that the yields of urea could be increased. However, by neither of these means was this possible; in fact, it was observed that a great excess of aquo salt tends to decrease the yield of urea.

In each experiment 0.100 g. of uric acid and 200 cc. of water were used and the solutions oxidized by shaking with oxygen under pressure.

#### TABLE I

	Percentage Decomposition with	Different	Amounts	of Aguo	SALT
	Aquo salt, g	0.30	0.40	0.50	1.00
	Time of oxidation	23 h.	48 h.	7.5 h.	44.5 h.
•	Urea formed, %	73.3	75.9	75.1	53.3

These results indicate that the reaction may be catalytic in nature. In this case very much smaller amounts of aquo salt should bring about a relatively large cleavage of uric acid, and this is indeed found to be the case. When amounts of aquo salt are used which correspond to  $^{1}/_{4}$  and  $^{1}/_{40}$  the amount necessary for a reaction taking place molecule per molecule, values of urea are obtained which are much greater than can result from a reaction taking place in equimolecular proportions. In fact, no stoichiometric relationship whatsoever can be seen between the amounts of aquo salt used and the urea formed.

Nevertheless, all of the uric acid cannot be brought into solution by these small amounts of aquo salt, and thus the completion of reaction is still dependent to some extent on the amounts of auto-oxidizing agent used.

These results find no analogy in the behavior of pyrimidines. For instance, if uracil is oxidized with amounts of aquo salt which correspond to  $^1/_6$  and  $^1/_{60}$  the amount necessary for a reaction taking place in equimolecular proportions, the respective amounts of urea obtained are considerably less than  $^1/_6$  and  $^1/_{60}$  of the calculated yield.

#### TABLE II

Comparison of Oxidation of Uric Acid and Uracil with Small Quantities of Aquo Salt

In each experiment 0.200 g. of uracil or 0.100 g. of uric acid and 200 cc. of water were used and the solutions oxidized by shaking with oxygen under pressure for 21.5 hours.

	1	2	3	4
Material used	0.2 g. uracil	0.2 g. uracil	0.1 g. uric acid	0.1 g. uric acid
Amt. of aquo salt, g	0.10	0.01	0.10	0.01
Frac. of cale. amt		1/60	1/4	1/40
Urea formed, %	6.4	0.28	47.3	16.7

The behavior of uric acid and aquo salt indicates the possibility that we are dealing with a case of true catalysis, that is, a molecule of aquo salt is able to function more than once in the activation of oxygen and uric acid. Ultimately, however, the delicate aquo salt molecule must break down under the strong oxidizing influence of pure oxygen under pressure, thus preventing its catalytic effect from continuing.

The Action of the System, Ferrous Sulfate Plus Oxygen.—It was found that the system, ferrous sulfate plus oxygen, is not able to bring about a cleavage of the uric acid molecule.

#### Experimental Part

Apparatus.—The same types of apparatus were used as have been previously described.¹

Analytical Methods.—The urea was determined quantitatively by the method of Fosse³ using the precautions mentioned in a preceding article.¹ Calculations are based on the assumption that each molecule of uric acid can break down to form two molecules of urea.

Experiments with Ferrous Carbonate Peroxide.—The uric acid was dissolved in aqueous sodium bicarbonate solution, to which was then added solid ferrous sulfate. No attempts were made to precipitate the ferrous carbonate in the absence of air. Urea determinations were made on aliquot portions of the clear solution.

Experiments with Sodium Pentacyano-aquo-ferroate.—A weighed portion of uric acid was added to an aqueous solution of the complex salt and the resulting suspension oxidized either by a stream of oxygen or by oxygen under a pressure slightly greater than one atmosphere. When oxidation was discontinued the suspended uric acid had always completely dissolved with the exception of Expts. 3 and 4, Table II.

Experiments with Ferrous Sulfate Plus Oxygen.—A weighed amount of uric acid was added to an aqueous solution of ferrous sulfate containing two molecular equivalents of ferrous sulfate per equivalent of uric acid. Oxidation was attempted by using oxygen under a pressure slightly greater than one atmosphere.

³ Fosse, Ann. chim., [9] 6, 13 (1916).

The author wishes to express her appreciation to Professor Treat B. Johnson and to Dr. Oskar Baudisch for their suggestions and criticisms during the progress of this work.

# Summary

- 1. The mild conditions under which uric acid is oxidized are emphasized.
- 2. The extent of cleavage of uric acid by means of complex iron salts is shown.
- 3. No mechanism is suggested, but it is demonstrated that an intermediate compound must be formed because the very sensitive xanthydrol test is obtained only after the oxidation mixture has been heated on the water-bath.
- 4. Experiments show that the oxidation of uric acid by means of [Fe(CN)₅H₂O]Na₃ may be catalytic in nature, and brought about by means of auxiliary valences. The latter is proved by the formation of a brilliant red solution during oxidation.

# CONDENSATIONS OF ALDEHYDES WITH RESORCINOL AND SOME OTHER AROMATIC HYDROXY COMPOUNDS

By Rajendra Nath Sen and Nripendra Nath Sinha

RECEIVED APRIL 20, 1923

The condensation of aldehydes with various aromatic hydroxy compounds has been previously studied by several investigators. A close study of these condensations brings out certain facts of great importance, as follows.

- 1. Though the modes in which these various condensations took place and the natures of the resulting products were different in many cases, yet in a few cases only two molecules of hydroxy compounds reacted with one molecule of the aldehyde, forming the pyrone ring with the elimination of water by the interaction of two hydroxyl groups in the *ortho* position to the reacting hydrogen atoms. The mode in which these condensations were carried out by the previous workers may be generally represented either as Type 1^{1f} or Type 2^{1e} (R is a phenyl residue).

2. Even in those few cases where such pyrone-ring formation took place, the xanthenes were first isolated and then oxidized by different oxidizing agents to the corresponding fluorones. For instance, in Möhlau and Koch's work^{1m} formaldehyde was first condensed with resorcinol by means of dil. sulfuric acid to form the xanthene; this xanthene was then isolated and in turn oxidized to fluorone by heating with concd. sulfuric acid, the reactions being represented thus,

HO OH HO OH dilute 
$$H_2SO_4$$
 HO OH HO OH  $H_2SO_4$   $H_1$   $H_2SO_4$   $H_1$   $H_2SO_4$   $H_1$   $H_2SO_4$   $H_1$   $H_2SO_4$   $H_1$   $H_2SO_4$   $H_1$   $H_1$ 

3. The condensing agents used in the previous work were alcohol, sodium hydroxide, moderately concd. sulfuric acid, or alcoholic sulfuric acid, which could not bring about pyrone-ring formation and oxidation in one stage.

The present investigation has been taken up with two objects in view. The first is to study whether any such pyrone ring giving rise to xanthene can be formed and whether such leuco compounds can be oxidized to the corresponding fluorones in one stage by using the same condensing agent, thereby opening up new possibilities of the preparation of benzeins.

The second object has its origin in the fact that the majority of the compounds prepared during the course of this investigation are fluorescent, the fluorescence depending on the nature and position of certain groups.

It is therefore of considerable interest to study the influence of the number and position of hydroxyl and carboxyl groups on the existence and intensity of fluoresence, and also the influence of temperature and nature of the solvent.

Attention was first directed to find out a suitable condensing agent for bringing about the desired condensation as indicated before. With this object in view, sulfuric acid, d. 1.750, was first used as the condensing agent, but with this acid a product was obtained at 100° the alkaline solution of which was not fluorescent, which was insoluble in cold water and had no dyeing property, that is, it did not exhibit the characteristic properties of a benzein. Consequently, the temperature was raised to 200°, but at that high temperature ofly tarry product was obtained.

Next, acid of d. 1.840 was used and the condensation was effected by heating the reacting substances on the water-bath for about an hour; sulfur dioxide was evolved. It was found by testing the product that the desired result was obtained, that is, the product was insoluble in cold water, the alkaline solution was fluorescent and it possessed all the characteristic properties of a benzein.

Most of the compounds described in this paper have been obtained by condensing aldehydes with some aromatic hydroxy compounds by using the same condensing agent.

In order to study whether the reaction is of general application, different aldehydes have been used such as (1) chloral hydrate and paraldehyde from the aliphatic series, (2) benzaldehyde and substituted benzaldehydes from the aromatic series, (3) furfurole from the heterocyclic group and (4) phenetole-azo-benzaldehyde-sulfonic acid, which is a complex aldehydic compound with an azo group.

The mechanism of the reaction is explained as follows. The reaction takes place in several stages: (1) the two hydrogen atoms of the hydroxy compound in *ortho* position to one hydroxyl group and in *para* position to the other, interact with aldehydic oxygen; (2) then the two hydroxyl groups interact with the elimination of one molecule of water, giving rise to xanthenes; (3) these in turn are oxidized to fluorones at the expense of sulfuric acid, as is evident by the evolution of sulfur dioxide, the formation of which was indicated by development of a blue color on starch-iodide paper and the odor; (4) these oxidized products then assume the quinonoid structure by the elimination of another molecule of water. These various steps are indicated on the next page.

This constitution as given in the case of resorcinol-benzein is supported by the following facts: (1) analytical results show that its molecular formula is  $C_{19}H_{12}O_3$ ; (2) analysis shows the formation of a monopotassium salt, and therefore indicates the presence of only one hydroxyl group; (3) analysis shows the formation of a monobenzoyl derivative, indicating

thereby the presence of one hydroxyl group; (4) the physical properties, such as fluorescence, intensity of color, affinity for wool and silk, etc., are also in agreement with the suggested constitution.

Most of the compounds prepared during the course of this investigation dye wool and silk from an acid bath in yellow, orange or brown shades depending on the number, position and nature of the substituting groups, bromo compounds producing red and bluish-red shades. This may be illustrated by the following examples.

Dye	Shade of original compound	Shade of bromo compound	Remarks
1. Resorcinol- benzein	Yellow	Red	
2. Resorcinol- hydroxy- benzein	More orange than 1	Deeper than 1	Influence of one more OH group
3. Resorcinol- dihydroxy- benzein	More orange than 1	More bluish than 1	Influence of two OH groups
4. Resorcinol- phenetole- azo-benzein- sulfonic acid	Brown	More bluish than 1	Influence of additional azo group

These compounds resemble the fluoresceins in constitution and properties. Taking resorcinol-benzein as the typical compound of this series and fluorescein to be the typical compound of the fluoresceins, a comparison of their properties is of interest. Both compounds are precipitated from their solutions in sodium hydroxide as yellowish-red powders; both dissolve in alcohol with yellow-red color and green fluorescence, the intensity of which is greater in the case of fluorescein; both dissolve in sodium hydroxide giving dark red concd. solutions, but on dilution fluorescein gives an orange-green fluorescence and resorcinol-benzein gives a red-green fluorescence fluorescence.

orescence; both compounds can be brominated to tetrabromo compounds which dye wool and silk beautiful red shades. One very interesting fact about these compounds is that resorcinol-benzein is quinonoid in all its tautomeric forms,

while fluorescein is not quinonoid in all its tautomeric forms.

According to Watson's rule² a dye which is quinonoid in all its tautomeric forms should produce a deep shade (violet, blue or green). Resorcinol-benzein is, however, not of such a deep color, although it produces a deeper, more orange shade than fluorescein.

The second object of the present investigation is to study (1) the influence of the number and positions of hydroxyl and carboxyl groups, and (2) the influence of the temperature and the nature of the solvent on the existence and the intensity of fluorescence of these compounds.

Taking fluorescein to be the typical fluorescent substance, a comparison between this compound and other compounds with different groups in different positions is interesting.

Resorcinol-benzein (I) (or the sodium salt) which differs from fluorescein (II) by the absence of one carboxyl group in the phenyl residue in *ortho* ² Watson, J. Chem. Soc., 105, 759 (1914).

position to the central methane carbon atom is less fluorescent than fluorescein. That the intensity of fluorescence of these compounds is much less than that of the fluoresceins appears to be due to the fact that the intermediate phase is not strictly symmetrical.³

To study the effect of an hydroxyl group in *ortho* and *para* positions to the central methane carbon atom, resorcinol-o-hydroxybenzein and resorcinol-p-hydroxybenzein have been prepared. Both compounds are fluorescent in sodium hydroxide solution, the *ortho* compound showing a bluish fluorescence and the *para* compound exhibiting a greenish fluorescence of slightly greater intensity.

The effect of an additional methoxy group in the *meta* position to the central methane carbon atom is not very marked as shown by resorcinol-p-hydroxy-m-methoxybenzein, whereas resorcinol-p-methoxybenzein exhibiting bluish fluorescence shows the effect of a methoxy group in the para position, resorcinol-benzein as well as resorcinol-p-hydroxybenzein exhibiting green fluorescence.

Resorcinol-*m*-carboxy-*p*-hydroxybenzein, the condensation product of 5-aldehydo-salicylic acid and resorcinol, showed the influence of the carboxyl group in the *meta* position to the central methane carbon atom. This compound is feebly fluorescent. It has been shown that the presence of an hydroxyl group in the *para* position to the central carbon atom produces fluorescence. Now, as this compound, which contains one hydroxyl group in the *para* position and one carboxyl group in the *meta* position to the central carbon atom, is feebly fluorescent, it is logical to conclude that its feebly fluorescent character is due to the presence of the carboxyl group in the *meta* position. Here it is interesting to note the marked effect on fluorescence of a carboxyl group when in different positions in the phenyl residue.

 $\beta$ -Resorcylic-acid-benzein and gallic-acid-benzein show the influence of substituents in the benzene nuclei associated with pyrone oxygen. The former, having one carboxyl group in Position 2 and another in Position 7, is fluorescent while the latter, having one carboxyl group in Position 1 and another in Position 8, is not. Non-fluorescence of the latter in sodium hydroxide is due to (1) the presence of hydroxyl groups in the 4 and 5 positions and (2) the unsymmetrical intermediate phase,

³ Hewitt's Theory of Double Symmetrical Tautomerism, *Proc. Chem. Soc.*, 16, 3 (1900).

One interesting fact about gallic-acid-benzein is that it is not fluorescent in alkaline solution, while its solution in coned. sulfuric acid is fluorescent. Instances of this type are already known; fluoran, for example, fluoresces in coned. sulfuric acid solution but not in alcoholic solution.

In pyrogallic-acid-benzein there are two hydroxyl groups in Positions 4 and 5, and also one in 6. This substance is not fluorescent. Its non-fluorescent character is most probably due to the presence of hydroxyl groups occupying positions *ortho* to pyrone oxygen, that is, the 4 and 5 positions. Such instances are also known in the case of fluorane derivatives.

Resorcinol-ethein, having a methyl group in place of the phenyl residue, is also fluorescent. Resorcinol-phenetole-azo-benzein-sulfonic acid is not fluorescent. This may be due to the presence of azo and sulfonic acid groups.

It is a curious fact that tetrabromo compounds of resorcinol-benzein, resorcinol-o-hydroxy-benzein, resorcinol-p-methoxy-benzein are non-fluorescent in sodium hydroxide, pyridine, and sulfuric acid solutions but are fluorescent in alcoholic solution, this fluorescence disappearing on dilution.

The effect of the influence of temperature on the intensity of fluorescence has been noted in a few cases. The fluorescence of certain substances, such as resorcinol-benzein, disappears at a higher temperature but reappears on cooling. This phenomenon has not yet received any satisfactory explanation. It may be due to the change of velocity of electrons and the consequent change in the period of vibration.

To study the influence of the nature of the solvent on the intensity and existence of fluorescence the following solvents were used: dil. aqueous sodium hydroxide, concd. sulfuric acid, redistilled ethyl alcohol, ether, glacial acetic acid, benzene, nitrobenzene, pyridine, acetone and in some cases methyl alcohol. From the observations recorded in the experimental part it may be concluded that the majority of compounds are fluorescent in sodium hydroxide and alcoholic solutions, and a few in pyridine and in sulfuric acid solutions. The majority of the substances, being insoluble in glacial acetic acid, benzene and ether, do not exhibit fluorescence in these liquids.

In consideration of the fact that the relation between chemical constitution and fluorescence has been very little investigated the results obtained during the course of this work have considerable theoretical interest.

# Experimental Part

1. Resorcinol-benzein  $C_{19}H_{12}O_3$  (I).—To a solution of 4.6 g, of dried resorcinol in 5 cc. of warm concd. sulfuric acid (d., 1.840) in a 300cc. conical flask fitted with an air condenser was added 2.2 cc. of dry benzaldehyde drop by drop and the mixture stirred constantly. Great heat was generated and an intense yellow color developed in the course of two or three minutes. When all of the benzaldehyde had been added, the flask with the contents was heated on the water-bath for about 45 minutes, when the odor of benzaldehyde was no longer perceptible. During the course of heating sulfur dioxide was evolved, as was evidenced by its odor and by the development of a blue color on starch-iodide paper.

When the mass became solid it was cooled, treated with ice-cold water, filtered and washed with cold water. The precipitate was dissolved in a solution of sodium hydroxide which was filtered and the original compound was reprecipitated with dil. hydrochloric acid, after which solution and precipitation were repeated. The product was finally crystallized from ethyl alcohol, when a microcrystalline yellow powder was obtained, and dried at 100°; yield, 3.8 g., or 74%. It is insoluble in cold water, ether, benzene, or glacial acetic acid, and is soluble in hot water (giving a yellow solution), in sodium hydroxide (a red solution), in coned. sulfuric acid (an orange solution), in acetone (a yellow solution), and in alcohol (a reddish-yellow solution). It imparts a redgreen fluorescence to sodium hydroxide solution and pyridine solution, and an orange-green fluorescence to sulfuric acid and alcoholic solutions. Its solution in sodium hydroxide becomes colorless when heated with zinc dust, and again becomes colored by oxidation on exposure to air. It does not melt below 290°. On heating the substance on a nickel spatula over the flame it decomposes without melting. It dyes wool and silk a yellow shade.

Analyses. Subs., 0.1520, 0.1600: CO₂, 0.4402, 0.4640;  $H_2O$ , 0.0564, 0.0593. Calc. for  $C_{19}H_{12}O_3$ : C, 79.16; H, 4.16. Found: C, 78.98, 79.09; H, 4.12, 4.11.

Potassium Salt.—Four g. of purified resorcinol-benzein was just neutralized with potassium hydroxide solution. The resulting salt solution was then filtered, the filtrate evaporated to a small bulk, and the neutral monopotassium salt was precipitated by alcohol. It was filtered off and finally crystallized from hot dil. alcohol as red crystals, which dissolve in water to give a red solution with red-green fluorescence.

Analysis. Subs., 0.1300:  $K_2SO_4$ , 0.0344. Calc. for  $C_{19}H_{11}O_3K$ : K, 11.99. Found: 11.8.

The Benzoate.—Five g. of pure resorcinol-benzein was benzoylated by the Schotten-Baumann process. There was thus obtained a light yellow powder which was purified by crystallization from alcohol. It melted at 141–142°.

Analyses. Subs., 0.1500, 0.1520:  $CO_2$ , 0.4373, 0.4430;  $H_2O$ , 0.0550, 0.0560. Calc. for  $C_{26}H_{16}O_4$ : C, 79.59; H, 4.08. Found: C, 79.44, 79.48; H, 4.07, 4.06.

2,3,5,7-Tetrabromo Derivative.—Five g. of the compound was brominated in alcohol by the slow addition of the calculated amount of liquid bromine. The product was crystallized from alcohol and was obtained as a red microcrystalline powder. It is soluble in sodium hydroxide solution (orange color, no fluorescence), in alcohol (orange color, feeble orange-green fluorescence), and insoluble in benzene or acetone. It dyes wool and silk a reddish-orange shade from an acid bath. It decomposes at about 200°.

Analysis. Subs., 0.1500: AgBr, 0.1866. Calc. for C₁₉H₈O₅Br₄: Br, 52.98. Found (Piria and Schiff's method): 52.93.

Resorcinol-benzein has been prepared previously by two other methods: (1) benzo-trichloride was condensed with resorcinol by heating the mixture on the paraffin-bath at 180° to 190° for five or six hours with zinc chloride; (2) benzoic acid was similarly condensed with resorcinol. The present method is simpler and more advantageous than the previous ones, as in this method less time and less energy (reaction temperature being the temperature of the water-bath) are required. The difficulty of the preparation of resorcinol-benzein by the earlier methods probably accounts for the fact that this substance did not gain so much importance as fluorescein.

2. Resorcinol-1'-hydroxybenzein.—A mixture of 4.6 g. of dried resorcinol, 2.4 cc. of salicylic aldehyde and 10 cc. of concd. sulfuric acid was heated on an oil-bath to 110° for 1¹/₂ hours. The product was then treated and purified in the same manner as described in the case of resorcinol-benzein. It is soluble in sodium hydroxide solution (orange color, red-blue fluorescence), in alcohol (yellowish-red color, no fluorescence), in

acetone (yellow color, no fluorescence), in nitrobenzene (yellow color, no fluorescence) or in pyridine (deep red color, dull green fluorescence), and is insoluble in glacial acetic acid, benzene or ether. It does not melt below 260°. It dyes wool and silk a yellow-ish-orange shade from an acid bath.

Analyses. Subs., 0.1450, 0.1420:  $CO_2$ , 0.3982, 0.3886;  $H_2O$ , 0.0508, 0.0508. Calc. for  $C_{19}H_{12}O_4$ : C, 75.00; H, 3.94. Found: C, 74.89, 74.63; H, 3.80, 3.98.

Tetrabromo Derivative.—Five g. of the substance was brominated by the slow addition of liquid bromine (1.5 cc.) to the alcoholic solution. The bromo compound was crystallized from alcohol and was obtained as red crystals; yield, 5.6 g. It is soluble in sodium hydroxide (red color, no fluorescence), in alcohol (orange-yellow color, feeble yellowish-green fluorescence), in coned. sulfuric acid (yellow solution, no fluorescence) or in pyridine (orange solution, no fluorescence). It decomposes at about 210° with change of color. It dyes wool and silk a red shade.

Analysis. Subs., 0.1512: AgBr, 0.1830. Calc. for  $C_{10}H_8O_4Br_4$ : Br, 51.58. Found: 51.52.

3. Resorcinol-2'-methoxy-3'-hydroxybenzein (III).—An intimate mixture of 6.6 g. of dried resorcinol with 4.6 g. of dried vanillin was added little by little to 10 cc. of coned. sulfuric acid (d., 1.840) in a conical flask with an air condenser, and the flask was heated on the oil-bath at 110–115° for about an hour. The subsequent process of purification was the same as in the case of the resorcinol-benzein. When crystallized from ethyl alcohol it formed a grayish-black, microcrystalline powder; yield, 5 g. It dissolves in sodium hydroxide solution (reddish-violet color, green fluorescence) and in coned. sulfuric acid (pink color, green fluorescence). It is insoluble in ether or benzene. It forms a bromo compound on treatment with liquid bromine, and dyes wool and silk from an acid bath with a yellowish-orange shade. It does not melt below 295°.

Analyses. Subs., 0.1600, 0.1301:  $CO_2$ , 0.4200, 0.3446;  $H_2O$ , 0.0599, 0.0487. Calc. for  $C_{20}H_{14}O_5$ : C, 71.80; H, 4.15. Found: C, 71.59; 71.74; H, 4.16, 4.17.

4. Gallic-acid-benzein (IV).—Six and eight-tenths g. of well-dried gallic acid was condensed with 2.1 cc. of dried benzaldehyde in the same manner as in the case of the resorcinol-benzein, except that in this case the reacting substances were heated on an oilbath to 120–125° for two hours. The substance was dissolved in sodium hydroxide and was reprecipitated by addition of dil. hydrochloric acid. It was then dissolved in 75% alcohol and the alcoholic solution was poured into hot water, when a precipitate was formed. The precipitate was again crystallized from hot alcohol, and a greenish microcrystalline powder was obtained; yield, 4 g. It dissolves in sodium hydroxide (deep red color, no fluorescence, and in coned. sulfuric acid (brownish-red color, red-green fluorescence). That the substance does not undergo any change in the sulfuric acid solution is proved by the fact that when the sulfuric acid solution is diluted with water the original substance is reprecipitated. It dissolves in acetone (yellowish-green color, no fluorescence), in alcohol (greenish color, no fluorescence), in pyridine (yellow color, no fluorescence), in alcohol (greenish color, no fluorescence), in pyridine (yellow color, no fluorescence)

cence), and in nitrobenzene (greenish solution); it is insoluble in glacial acetic acid in the cold but dissolves slightly when heated, and is insoluble in benzene and ether. It is a mordant dye, giving a brown shade in chrome-mordanted wool. It softens at 198°.

Analyses. Subs., 0.1300, 0.1640:  $CO_2$ , 0.2941, 0.3712;  $H_2O$ , 0.0345, 0.0439. Calc. for  $C_{21}H_{12}O_9$ : C, 61.76; H, 2.94. Found: C, 61.69, 61.73; H, 2.95, 2.97.

5. Condensation of Chloral Hydrate and Resorcinol (V).-To the solution of dried resorcinol in sulfuric acid was added 4.95 g. of dried chloral hydrate. The first action of sulfuric acid was to liberate the aldehyde chloral which acts on resorcinol. The reaction mixture was heated on the water-bath, when there was much frothing and copious fumes of hydrogen chloride (detected by the formation of ammonium chloride) and sulfur dioxide (detected by starch-iodide paper) escaped. The heating was continued for four to five hours. The cold mass was treated with ice-cold water. As the substance is soluble in cold water, the least quantity of water, containing a little hydrochloric acid, was used in washing. The same method of purification was adopted as in the case of the first compound; yield, 2 g. It dissolves in sodium hydroxide solution (red color, red-green fluorescence) and in sulfuric acid (yellow color, no fluorescence). One peculiarity of this substance is that the red color of the alkaline solution changes to orange on dilution. It is insoluble in glacial acetic acid, benzene, ether or acetone. The substance did not give any test for halogen. It dissolves in sodium carbonate solution with evolution of carbon dioxide. It dyes wool and silk a very light yellow. It does not melt below 295°.

Analyses. Subs., 0.1400, 0.1200: CO₂, 0.3362, 0.2877; H₂O, 0.0390, 0.0335. Calc. for C₁₄H₈O₅: C, 65.62; H, 3.12. Found: C, 65.49, 65.38; H, 3.09, 3.10.

6. Resorcinol-ethein (VI).—Four and four-tenths g. of dried resorcinol was condensed with 1.76 cc. of paraldehyde in the usual manner. Ice-cold water was poured into the solid mass, the precipitate thus formed was dissolved in sodium hydroxide solution, the compound reprecipitated by dil. hydrochloric acid, the solution filtered, and the substance dried, washed with benzene and finally crystallized from 75% alcohol. It was obtained as a black, microcrystalline powder. It does not melt or decompose below 290°. It dissolves in sodium hydroxide solution (red color, red-green fluorescence, the intensity of which is almost equal to that of resorcinol-benzein). It is soluble in alcohol (orange color) and is insoluble in ether, benzene or nitrobenzene. It dyes wool and silk a yellowish-orange shade.

Analyses. Subs., 0.1200, 0.1350:  $CO_2$ , 0.3264, 0.3665;  $H_2O$ , 0.0476, 0.0534. Calc. for  $C_{14}H_{19}O_3$ : C, 74.34; H, 4.40. Found: C, 74.18, 74.04; H, 4.40, 4.39.

7. Resorcinol-phenetole-azo-benzein-sulfonic Acid (VII).—A thorough mixture of 6.8 g. of recrystallized azo-aldehyde⁴ with 4.4 g. of resorcinol in a mortar was added, little

⁴ Green and Sen, J. Chem. Soc., 97, 2243 (1910).

by little, to 10 cc. of sulfuric acid. A deep red color developed and great heat was generated. The mixture was thoroughly stirred and heated on an oil-bath at 130–140° for three hours. Sulfur dioxide was evolved. The solid mass was treated with ice-cold water. A portion was tested to prove the absence of azo-aldehyde, by means of phenylhydrazine acetate. The usual method of purification was followed; yield, 3 g. It dissolves in sodium hydroxide solution (brown color), in alcohol (brownish-yellow color) and in sulfuric acid (brown-red color). It is insoluble in nitrobenzene or ether. It does not fluoresce in any of the solvents, perhaps owing to the presence of sulfonic acid and azo groups. It dyes wool and silk from an acid bath a brownish-yellow shade.

Analyses. Subs., 0.1679: 8.5 cc. of  $N_2$  (30°, 760 mm.). Calc. for  $C_{27}H_{20}O_7N_2S$ : N, 5.5; S, 6.20. Found: N, 5.50; S, 6.00.

8. Resorcinol-furfurein (VIII).—To a solution of 6.6 g. of resorcinol in 10 cc. of sulfuric acid in a flask surrounded by freezing mixture was added 2.6 cc. of furfurole drop by drop while the mixture was constantly stirred. The substance assumed first a blue, then a reddish-violet and finally a blue-black color. After all of the furfurole had been added the flask was heated on the water-bath for half an hour, when sulfur dioxide was evolved. The substance is highly soluble in water. Therefore sulfuric acid was removed as barium sulfate by the addition of barium carbonate. The solution was filtered, the filtrate was evaporated to a small bulk and coned. hydrochloric acid was added. The solution was filtered and the precipitate was collected and finally crystallized from alcohol; yield, 3 g. It is soluble in sodium hydroxide solution (red color, red-green fluorescence), in coned. sulfuric acid (reddish-yellow color) and is insoluble in benzene or ether. It does not melt below 280°.

Analyses. Subs., 0.1200, 0.1110:  $CO_2$ , 0.3225, 0.2985;  $H_2O$ , 0.0394, 0.0361. Calc. for  $C_{17}H_{19}O_4$ : C, 73.40; H, 3.60. Found: C, 73.30, 73.34;  $H_2O$ , 3.65, 3.61.

9. Resorcinol-p-hydroxy-m-carboxybenzein (IX).—A mixture of 5 g. of the 5-aldehydo-salicylic acid (prepared by Cohen's modification of Reimer and Tieman's method⁵) with 8.8 g. of resorcinol was added to 20 cc. of sulfuric acid in a conical flask while it was constantly stirred. The mixture was heated on the water-bath for about an hour. At the end of the reaction the product was treated with ice-cold water, purified in the usual manner and obtained as a yellow powder; yield, 3 g. It dissolves in sodium hydroxide solution (red color, red-green fluorescence), in sulfuric acid (yellow color, no fluorescence), in alcohol (yellow color, no fluorescence) and in pyridine (reddish-yellow color, no fluorescence), and is insoluble in nitrobenzene, ether or benzene. It dyes wool and silk a bright yellow shade. It does not melt below 295°.

Analyses. Subs., 0.1300, 0.1350:  $CO_2$ , 0.3241, 0.3385;  $H_2O$ , 0.0409, 0.0428. Cale for  $C_{20}H_{12}O_6$ : C, 68.96; H, 3.44. Found: C, 67.99, 68.38; H, 3.49, 3.52.

10.  $\beta$ -Resorcylic-acid-benzein (X).—Five and six-tenths g. of  $\beta$ -resorcylic acid was condensed with 2.2 cc. of benzaldehyde in the same manner as in the case of re-

⁵ Wayne and Cohen, J. Chem. Soc., 121, 1022 (1922).

sorcinol-benzein. The usual method of purification was adopted, giving a yellow powder; yield, 2.5 g. It is soluble in sodium hydroxide solution (orange color, green fluorescence), in sulfuric acid (yellow color, no fluorescence) and in alcohol (orange-yellow color, no fluorescence).

Analyses. Subs., 0.1200, 0.1220:  $CO_2$ , 0.2944, 0.2997;  $H_2O$ , 0.0346, 0.0343. Calc. for  $C_{21}H_{12}O_7$ : C, 67.02; H, 3.19. Found: C, 66.91, 66.99; H, 3.20, 3.12.

11. Resorcinol-3-methoxybenzein.—A mixture of 4.4 g. of resorcinol, 2.5 cc. of anisaldehyde and 10 cc. of sulfuric acid was heated to 110–115° on an oil-bath for about an hour. The usual method of purification was adopted and the substance was obtained as a yellow powder. It does not melt or decompose below 285°. It dissolves in sodium hydroxide solution (red color, bluish fluorescence), in alcohol (yellow color, no fluorescence), in sulfuric acid (dark red color, no fluorescence) and in pyridine (light yellow color, no fluorescence), and is insoluble in ether or benzene. It dyes wool and silk from an acid bath a bright yellow shade.

Analyses. Subs., 0.1220, 0.1200:  $CO_2$ , 0.3367, 0.3308;  $H_2O$ , 0.0485, 0.0475. Calc. for  $C_{20}H_{14}O_4$ : C, 75.40; H, 4.40. Found: C, 75.27, 75.18; H, 4.41, 4.39.

Tetrabromo Derivative.—Five g. of the pure substance was brominated in the usual manner by the slow addition of 2.5 cc. of liquid bromine. The red precipitate thus obtained was crystallized from alcohol as a red powder. It is soluble in sodium hydroxide solution (deep red color, no fluorescence), in alcohol (reddish-orange color, greenish-orange fluorescence) and in concd. sulfuric acid (reddish-yellow color, no fluorescence). It does not melt, but decomposes at 200°, and dyes wool and silk a red shade.

Analysis. Subs., 0.1200: AgBr, 0.1421. Calc. for  $C_{20}H_{10}O_4Br_4$ : Br, 50.46. Found: 50.30.

12. Pyrogallol-benzein (XI).—A solution of 7.5 g. of pyrogallic acid in 20 cc. of concd. sulfuric acid was condensed with 3.15 cc. of benzaldehyde in the usual manner, and the product, purified as described above, obtained as a brown powder; yield, 2.5 g. It dissolves in sodium hydroxide (yellow solution, no fluorescence), in sulfuric acid (brownish-red solution, no fluorescence), in pyridine (red solution, no fluorescence), in nitrobenzene (red solution, no fluorescence). It does not melt below 295°.

Analyses. Subs., 0.1350, 0.1310:  $CO_2$ , 0.3516, 0.3419;  $H_2O$ , 0.0450, 0.0433. Calc. for  $C_{12}H_{12}O_4$ : C, 71.25; H, 3.75. Found: C, 71.03, 71.17: H, 3.70, 3.67.

# Summary

- 1. Compounds of the type of benzeins have been obtained in good yields by the condensation of various aldehydes with resorcinol and other hydroxy compounds in the presence of concd. sulfuric acid at temperatures varying from 100° to 130°.
- 2. These compounds are more or less fluorescent, the intensity of fluorescence in sodium hydroxide solution varying with the number and the position of hydroxyl and carboxyl groups. Thus, (1) in the phenyl residue R, the ortho position to the central carbon atom is most favorable and the meta position is most unfavorable for the carboxyl group to excite fluorescence; (2a) in the phenyl residue R, the ortho and para positions to the central carbon atom are also favorable for the hydroxyl group, although the effect is not so marked as in the case of carboxyl groups; (2b) in the benzene nuclei associated with the pyrone ring, Position 6 or 3 is

most favorable and 4 and 5 positions are most unfavorable for hydroxyl groups; (3) the influence of hydroxyl groups on fluorescence is greater when they occur in the benzene nuclei than when they occur in the phenyl residue, whereas the influence of carboxyl groups is greater in the phenyl residue than in the benzene nuclei.

3. Bromo derivatives of these compounds which have been studied do not fluoresce in any other ordinary solvents except alcohol.

#### SOME CACODYL DERIVATIVES

By Frank A. Lee, Curtis Thing and William M. Dehn Received June 9, 1923

#### General

The classical investigations of Robert Bunsen in the cacodyl series have remained substantially free from revision¹ since their publication (1837–1843). This paper develops some new compounds of this series and also concerns itself with reinvestigations of some of Bunsen's compounds, for the purposes both of fixing their formulas and of improving their yields. Though some have been obtained through substitution and oxidation, most of the new compounds herein described are additive or are hydrolytic products of such additive compounds. It is of special interest to note that one chlorine atom of the pentavalent arsenic compounds is characteristically susceptible to hydrolysis.

# **Experimental Part**

Cacodyl was prepared in large quantities by the usual method² and was then converted into cacodyl chloride³ by the use of mercuric chloride. It boiled⁴ at 109°.

Preparation of Cacodyl Bromide. Molecular quantities of potassium bromide and cacodyl chloride with 3 to 4 volumes of absolute alcohol were heated for 4 to 5 hours on a water-bath under a return condenser. Practical exclusion of air is advisable to avoid formation of the hydrated oxybromide. The reaction mixture was distilled from a sand bath as long as any distillate was obtained. The latter was treated with 5 to 10 volumes of water to precipitate the cacodyl bromide, which was then separated, dried with calcium chloride and fractionated. The yield of the bromide, boiling at 130°, was nearly quantitative.

Ostwald's "Klassiker der Exakten Wissenschaften," No. 27, pp. 138-148. Baeyer recalculated some of Bunsen's data with revised atomic weights and proposed some alternate formulas.

² (a) Bunsen, Ann., 37, 6 (1841); (b) 107, 257 (1858). This Journal, 35, 2 (1906).

³ (a) Ref. 2a, p. 30; (b) Ann., 42, 22 (1842).

⁴ Bunsen gave the boiling point as "over 100°."

⁵ Ref. 2a, p. 33. Bunsen prepared this compound in accordance with the reaction,  $[(CH_3)_2As]_2O + 2HgCl_2 + 2HBr \longrightarrow 2(CH_3)_2AsBr + 2HgCl_2 + H_2O.$ 

Cacodyl Iodide.  6 —This was prepared in an analogous manner in nearly quantitative yields. It boiled at 155–160  $^\circ$ .

Cacodyl Cyanide.8—This was prepared from cacodyl chloride and potassium cyanide in an analogous manner. Satisfactory yields of oil boiling at 138° were obtained. Since the cyanide was not found to be excessively poisonous, it probably has the cyanide and not the isocyanide structure. This compound will be studied further.

Cacodyl Chloride and Metallic Sodium.—Equimolecular quantities of the two materials in absolute ether slowly yielded cacodyl and sodium chloride.  $2(CH_3)_2AsCl + 2Na \longrightarrow [(CH_3)_2As]_2 + 2NaCl$ .

Bunsen's "Basic Cacodyl Superchloride."—Cacodyl chloride was found to be oxidized when in contact with moist air, giving rise to odorless, glistening, transparent, prismatic needles. The compound is best prepared by drawing moist air through an ether solution of cacodyl chloride. Dry air gives no crystals.

Analyses. Calc. for (CH₃)₂As(OH)₂Cl: C, 13.75; Cl, 20.32. Found: C, 13.66; Cl, 20.10.

The substance melts at 85°, is soluble in water and alcohol, and is insoluble in ether, chloroform and carbon disulfide. When dissolved in alcohol and reprecipitated by ether it melted at 92° and then contained only 18.00% of chlorine. Bunsen prepared this compound by the action of coned. hydrochloric acid on cacodylic acid: (CH₃)₂AsO.-OH + HCl  $\longrightarrow$  (CH₃)₂As(OH)₂.Cl. Our method of preparation led to the same compound:  $2(\text{CH}_3)_2\text{AsCl} + O_2 + 2\text{H}_2\text{O} \longrightarrow 2(\text{CH}_3)_2\text{As}(\text{OH})_2\text{Cl}$ . A better name for it is hydrated cacodyl oxychloride or simply basic cacodyl chloride.

# Reactions of Cacodyl Chloride with Metallic Chlorides

Mercurous Chloride.—Equimolecular quantities of the two compounds under water slowly yielded a white powdery additive compound. This mixture when boiled yielded cacodyl chloride, mercury, hydrochloric acid and cacodylic acid.  10  (CH₃)₂AsCl + 2 HgCl + 2H₂O  $\longrightarrow$  (CH₃)₂AsO.OH + 3HCl + 2Hg.

Mercuric Chloride.—Equimolecular quantities of the compounds quickly yielded an odorless, white, solid additive compound. When this was heated with water it yielded mercury, mercurous chloride, hydrochloric and cacodylic acids. The hot aqueous filtrate gave odorless glistening white rhombic leaflets, which were decomposed but not melted at 210°.

Analysis. Calc. for (CH₂)₂AsCl(OH)HgCl: Cl, 18.02. Found: 17.98.

Mol. wt. Calc. 393. Found (ebullioscopic method with water): 320.

This compound develops with hydrochloric acid the odor of cacodyl chloride. It is easily decomposed by hot aqueous solutions of alkalies and alkali carbonates. Its formation is explained by the equations,  $(CH_3)_2AsCl + HgCl_2 \longrightarrow (CH_2)_2AsCl_2.HgCl$ ;  $2(CH_3)_2AsCl_2.HgCl + 3H_2O \longrightarrow (CH_3)_2AsCl(OH)HgCl + (CH_3)_2AsO_2H + 3HCl + HgCl$ . Obviously the substance is an additive compound of mercuric chloride and

⁶ Ref. 2a, p. 32. Prepared by Bunsen like the bromide.

⁷ Ann., 92, 364 (1854).

⁸ Ref. 2a, p. 23. Bunsen distilled mixtures of cacodyl and mercuric cyanide and obtained a very poisonous product melting at 33° and boiling at 140°.

⁹ Bunsen's "hydrated cacodyl chloride," (CH₃)₂As₂O.2HCl, is closely related. Bunsen's "basic chlorcacodyl" and "cacodyl superchloride" were shown by Baeyer to be, respectively, a mixture of cacodyl oxide with cacodyl chloride, and (CH₃)₂As(OH)Cl₂.

¹⁰ Compare this reaction with that of mercurous chloride and dimethylarsine. Am. Chem. J., 35, 35 (1906).

cacodyl hydroxide.¹¹ Its solubility in water and easy decomposition by acids and alkalies suggests its possible usefulness in therapeutics. The yield when the substance was prepared above was about 20%. When 1 g. of magnesium oxide was added to 20 g. of the initial additive compound in 400 cc. of water, a 42% yield was obtained. With 2 g. of magnesium oxide, however, no yield at all was obtained. When the 1 g. of magnesium oxide was replaced by 2.5 g. of calcium carbonate, a 61% yield was recovered, but with 5 g. of calcium carbonate no yield was obtained. These experiments show that one molecular equivalent of alkali leads to a maximum yield, but two molecular equivalents destroy it.

Cuprous Chloride.—When 1.5 g. of anhydrous cuprous chloride and 2.4 g. of cacodyl chloride were brought together under petroleum ether, the mixture shaken and permitted to stand, a white additive compound was formed. It was filtered, washed with petroleum ether and dried in a vacuum.

Analysis. Calc. for (CH₃)₂AsCl.2CuCl: Cl, 31.42. Found: 31.79.

Cupric Chloride.—When equal weights of anhydrous cupric chloride and cacodyl chloride were brought together in petroleum ether, a dark gray-green, additive compound was formed.

Analysis. Calc. for (CH₃)₂AsCl.CuCl₂: Cl, 38.69. Found: 39.19.

The substitution of ordinary ether for the petroleum ether in this preparation yielded a white hydrolytic product. 12 

Analysis. Calc. for (CH₃)₂AsOH.CuCl₂: Cl, 27.64. Found: 27.70.

When the anhydrous cupric chloride and cacodyl chloride were brought together in absolute ether, the gray product first formed changed to tan and finally to white. Ethyl chloride was found in the reaction ether.

Analysis. Calc. for [(CH₃)₂As]₂O.2CuCl₂: Cl, 28.65. Found: 28.66.

Ferric Chloride.—A mixture of equimolecular quantities of cacodyl chloride and ferric chloride was allowed to stand for months in absolute ether. Green crystals of ferrous chloride were deposited. That the ether contained (CH₃)₂AsCl₃, was proved by its hydrolysis of the latter to caeodylic acid.

# Summary

Methods are described for the preparation of the bromide, iodide and cyanide of cacodyl and of basic cacodyl chloride, from the chloride. Bunsen's work on "Mercuric chloride cacodyl oxide" has been reinvestigated and the new data are presented. Four new compounds of cacodyl chloride and the copper chlorides are described.

SEATTLE, WASHINGTON

This formula, however, is disproved by the molecular weight and by Bunsen's own analytical data.

Analyses. Calc. for  $(CH_3)_2AsCI(OH)HgCl$ : C, 6.09; H, 1.80; Cl, 18.02; Hg, 50.97. Calc. for  $[(CH_3)_2As]_2O.2HgCl_2$ : C, 6.24; H, 1.57; Cl, 18.44; Hg, 50.17. Found (by Bunsen): C, 6.25; H, 10.76; Cl, 18.01; Hg, 50.76.

It is formed by hydrolysis of the initial additive compound of Bunsen. See Am. Chem. J., 40, 127 (1908).

¹² See Ostwald, Ref. 1, p. 77, for the instability of Bunsen's compound prepared from cacodyl oxide, hydrochloric acid and cuprous chloride.

¹¹ This compound agrees in all of its properties with the "Mercuric chloride cacodyl oxide" prepared by Bunsen:  $[(CH_3)_2As]_2O + 2HgCl_2 \longrightarrow [(CH_3)_2As]_2O.2HgCl_2$ .

A FURTHER STUDY OF THE NEUTRAL AMMONIUM SALTS OF
SOME ORGANIC ACIDS AND THEIR SUBSTITUTED
DERIVATIVES

Eighth Communication¹

By LeRoy McMaster and Paul K. Pratte Received July 2, 1923

This work is a continuation of the investigation which has been in progress in this Laboratory on the preparation and properties of the neutral ammonium salts of organic acids and their substituted derivatives. The salts described in this paper were, with slight modifications in several instances, prepared by the same general method as was used in the previous investigations, that is, by passing dry ammonia into solutions of the acids in those anhydrous organic solvents in which their salts were found to be insoluble. When it was found that an acid and its ammonium salt were both soluble in a certain solvent, the solution of the ammonium salt was poured into an excess of another solvent in which the salt was insoluble. In several cases it was necessary to evaporate the solutions nearly to dryness before the salts crystallized. In the case of acetyl m-aminobenzoic acid, it is insoluble in all the common organic solvents that do not react with ammonia and its solubility in water is very slight. It is soluble in concd. ammonium hydroxide. The neutral ammonium salt was thus prepared by dissolving the acid in coned. ammonium hydroxide, evaporating the solution to dryness, and then passing ammonia into an alcoholic suspension of the residue.

Of the neutral salts described in this paper none has been previously prepared except those of phenoxyacetic acid² and 2,5-dichlorobenzene sulfonic acid.³ They were prepared by neutralizing an aqueous solution of the acid with ammonium hydroxide. The ammonium 1,2,4-dinitro benzoate was described in a previous paper,⁴ but we have determined its solubilities and recorded them in this work.

Solubility determinations were made of only the stable salts by the analytical method. By this method the salt, in excess, was stirred with the solvent at a definite temperature until equilibrium was reached. The excess of salt was allowed to settle and the clear liquid decanted off into a weighed evaporating dish and immediately weighed. When the solvent had completely evaporated the evaporating dish was again weighed. From the differences in weight the amount of salt soluble in the solvent at the given temperature could be calculated. All the solubility determinations.

nations were carried out at  $20^{\circ}$ , which temperature was maintained in an automatic water thermostat. A large test-tube was used to hold the solubility mixture and was fitted at the top with a mercury seal to prevent the absorption of water vapor from the air by the solvent. This seal was constructed by sinking a piece of glass tubing (a 25mm, section of a large test-tube) into a cork containing a glass bearing for the stirrer. The space between the tube and the bearing was then filled with mercury. A second tube, smaller than the first, was then tightly fastened to the stirring rod by means of a cork so that when the stirrer extended to the bottom of the test-tube, the second tube fitted within the bearing and the large tube at the same time dipped below the surface of the mercury. In this manner the contents of the test-tube could be sealed against contact with air and at the same time the solution thoroughly stirred at about 200 r.p.m. It was found by experiment that 20 minutes was sufficient to bring the

#### REDUCTION OF SEMICARBAZONES

By E. J. Poth and J. R. Bailey Received August 8, 1923

#### Introduction

The Skita method of reduction with colloidal platinum as catalyst, as shown in a previous communication from this Laboratory, is of service in converting semicarbazones to the corresponding semicarbazides where other methods of reduction have produced only negative results. Certain semicarbazones, such as glyoxylic acid semicarbazone and benzal semicarbazone, are readily reduced with sodium amalgam without molecular cleavage, but it has been quite definitely determined that reduction in the desired way with sodium amalgam succeeds only when an electronegative radical is joined to the carbon of the C—N complex. From the experiments described in this paper it appears probable that catalytic reduction with colloidal platinum is of general application in the conversion of semicarbazones to the corresponding semicarbazides.

Conditions have been established for obtaining excellent yields of semicarbazides with a minimum amount of platinum; for example, carvone semicarbazone and hexanone semicarbazone can be reduced with a yield of 80% where the semicarbazone and 10% platinic chloride solution are employed in the ratio of  $10~\rm g$ . to  $1~\rm cc$ . It is necessary in the case of camphor and fenchone, terpene ketones of similar structure, to employ for the reduction of their semicarbazones a much larger amount of platinic chloride. Camphor

- ¹ Neighbors, Foster, Clark, Miller and Bailey, This Journal, 44, 1557 (1922).
- ² Rupe and Oestreicher, Ber., 45, 30 (1912).
- ³ Darapsky and Prabhakar, Ber., 45, 2625 (1912). Bailey and Read, This Journal, 36, 1751 (1914).
  - 4 Kessler and Rupe, Ber., 45, 26 (1912).

semicarbazone and platinic chloride are employed in the ratio of  $1\,\mathrm{g}$ . to  $1\,\mathrm{cc}$ , while in the case of fenchone semicarbazone the ratio is  $1\,\mathrm{g}$ . to  $4\,\mathrm{cc}$ .

It has been found in the catalytic reduction of the C-N complex to form basic products that the reduction is greatly facilitated by the presence of an acid for salification, but the reductions described on different semicarbazones, as shown in the experimental part of this article, give maximum yields with great variations in the amount of hydrochloric acid present. In the reduction of hexanone semicarbazone the hydrochloric acid, liberated from the platinic chloride used, suffices for a completion of the reaction, although this represents only a small fraction of the acid required for converting the hexahydrophenyl semicarbazide formed to its hydrochloride. With carvone, camphor and menthone semicarbazones maximum vields are obtained when only half of the calculated amount of hydrochloric acid is present, whereas in the case of acctone and fenchone semicarbazones it is necessary to employ the calculated amount of hydrochloric acid. The advantage of using a minimum amount of hydrochloric acid, in the case of the semicarbazones that readily hydrolyze, is apparent but, on the other hand, where the semicarbazide is difficultly, and its hydrochloride readily, soluble, a sufficiency of the mineral acid has the advantage of effecting clear solution at the end of the reduction. In order to keep down the acid concentration, it will frequently be found advisable to add the hydrochloric acid gradually at different stages of the reduction. Of the semicarbazones investigated, the velocity of hydrogenation is greatest in the case of those of hexanone, carvone and acetone, and slowest in that of fenchone, while camphor and menthone semicarbazones, in the order named, follow fenchone semicarbazone in their slowness of reduction. The effect of temperature here has not been studied, but it is quite evident that at higher temperatures there would be danger of increased hydrolvsis of the semicarbazones.

The reduction of carvone semicarbazone is of interest because it contains two double bonds between carbons and a third between a carbon and a nitrogen. It is certain that the reduction of the C=N complex does not precede that of the C=C complexes, because, with one-third of the calculated hydrogen consumed, there remains, even with one molecular equivalent of hydrochloric acid present, a large amount of insoluble semicarbazone. The indications are that the difference in velocities of the reduction of the unsaturated complexes is not sufficient to allow of isolation of partial reduction products of carvone semicarbazone, at least with satisfactory yields. However, no experiments were made in this direction.

The aliphatic and hydro-aromatic semicarbazides, in contrast to the aryl

⁵ Compare A. Skita, *Ber.*, **52**, 1521 (1919). Lochte, Bailey and Noyes, This Journal, **43**, 2599 (1921).

semicarbazides, form stable salts that do not lose hydrochloric acid on standing. However, the hydrochlorides in aqueous solution react acid to methyl orange. All semicarbazides add a molecule of phenyl isocyanate and with acid chlorides yield acyl derivatives which with caustic alkalies lose a molecule of water to form triazoles.6 They apparently react with phenyl mustard oil, but the products could not be made to crystallize. The hydro-aromatic semicarbazides react with nitrous acid, but crystalline nitroso compounds were not isolated. On oxidation this type of semicarbazides yields azo compounds that cannot be isolated because of the ease with which they invariably transpose to the isomeric, colorless semicarbazones.7 All of the hydro-aromatic semicarbazides investigated give waterinsoluble condensation products with formaldehyde8 which possess various solubilities in organic solvents and are neutral to both acids and alkalies. In no instance was a way of recrystallizing these substances found. Experiments aimed at acid and alkali hydrolysis of the hydro-aromatic semicarbazides to the corresponding hydrazino compounds did not produce the desired results. The decomposition of hexahydrophenyl semicarbazide at elevated temperatures is discussed in the succeeding article.

# Experimental Part

General Conditions for Reduction of Semicarbazones.-In the case of most semicarbazones, it is advisable to prepare the colloidal platinum solution before the addition of the substance to be reduced. To a mixture of 200 cc. of water, 100 cc. of methyl alcohol, 5 cc. of 10% chloroplatinic acid and a few drops of seeding solution is added 0.4 g. of gum arabic, and the mixture is shaken in the usual way with hydrogen under pressure until a deep black color develops. A grayish, colloidal solution at this stage indicates a catalyst of poor efficiency and should not be used, since the physical state of the colloid has a pronounced effect on the rate of hydrogenation and the yield of semicarbazide. The semicarbazone is next added to the platinum solution, followed by the requisite amount of hydrochloric acid, and the reduction carried out with agitation in the usual way with an initial pressure of hydrogen registering  $2^{1}/_{3}$  atmospheres (35 lbs.). is advisable to hydrogenate semicarbazones with a pressure never lower than  $1^2/_3$  atmospheres (25 lbs.). In the reductions described, 33% alcohol was employed as solvent with the ratio of solvent to platinic chloride of 60 cc. to 1 cc. In all cases except that of benzal semicarbazone 1 g. of semicarbazone was reduced in 6 cc. of the colloidal solution. As a rule, semicar-

bazones and, unless present as hydrochlorides, many semicarbazides are not completely soluble in this concentration of alcohol. A higher concentration is objectionable because, frequently, it breaks the colloid and in any event has a tendency to inactivate the catalyst.

The general method of procedure in carrying out the reduction of semicarbazones and the isolation of the semicarbazide formed is given under the preparation of fenchyl semicarbazide. The additional data in the following table are self-explanatory.

TABLE I
HYDROGENATION EXPERIMENTS

Semicarbazide formed	Semicar- bazone G.	Methyl alcohol Cc.	Water Ce.	HC1a	Pt sol. Cc.	Time Hours	Yield %
Fenchyl	10	50	10	calc.	43	24	100
Carvomenthyl	50	100	200	$^{1}/_{2}$ calc.	5	5	80
Hexahydrophenyl	50	100	200	trace	5	3	80
Menthyl	50	100	200	$^{1}/_{2}$ calc.	5	2.75	80
isoPropyl	50	100	200	cale.b	5	6	76
Benzyl	25	100	200	cale.	5	2.5	50
Bornyi	10	20	40	$^{1}/_{2}$ calc.	10	20	100

^a Coned, hydrochloric acid was used so as to keep the volume of solution a minimum.

In all the reduction experiments 0.4 g. of gum arabic was used as a protective colloid for each 300 cc. of colloidal solution.

Fenchyl Semicarbazide.—To 43 cc. of 10% chloroplatinic acid, in a pressure bottle, are added 0.5 g. of gum arabic in 10 cc. of water, a few drops of seeding colloid, 50 cc. of methyl alcohol, 1 cc. of hydrochloric acid (d., 1.2) and 10 g. of fenchone semicarbazone, and the mixture is then shaken at over 2 atmospheres' pressure until the theoretical amount of hydrogen is absorbed. Finally, the colloid is broken with acetone, the filtered solution evaporated in a vacuum on a water-bath, and the fenchyl semicarbazide precipitated with ammonium hydroxide. Conditions have not been established for isolating salts of fenchyl semicarbazide which, so far as examined, do not possess good crystallizing properties. Fenchyl semicarbazide is practically insoluble in water, ether and petroleum ether, readily soluble in dilute mineral acids, chloroform and ethyl alcohol, slightly soluble in benzene and moderately soluble in acetic ether. It dissolves in glacial acetic acid but precipitates on dilution. For purification, it can be recrystallized from ethyl acetate in short needles, melting at 181° with decomposition.

Analyses. Calc. for  $C_{11}H_{21}ON_3$ : C, 62.56; H, 9.95; N, 19.91. Found: C, 62.51; H, 10.25; N, 20.02.

Benzoyl-fenchyl Semicarbazide,  $C_{10}H_{17}N(COC_6H_5)NHCONH_2$ .—To 5 g. of fenchyl semicarbazide, dissolved in 300 cc. of dry benzene, are added 4 cc. of benzoyl chloride and 5.3 g. of sodium bicarbonate. After the mixture has been refluxed for four hours on a

^b The acid was added in three equal portions, one at the beginning and the other two when the hydrogen absorbed equalled  $^{1}/_{3}$  and  $^{2}/_{3}$ , respectively, of the amount required.

^c This semicarbazone was not isolated, but benzaldehyde and semicarbazide hydrochloride, in calculated amounts, were added to the reduction mixture.

⁹ Wallach, Ann., 353, 211 (1907).

boiling water-bath, the benzoyl derivative separates as a gelatinous mass. The solvent is then distilled and the residue extracted with 95% alcohol. From the alcoholic solution, the benzoyl derivative is precipitated on dilution. On recrystallization from glacial acetic acid containing a few drops of water, it is obtained as a fine, crystalline powder which softens at 223° and decomposes at 226°. Like the other benzoyl derivatives described in this paper, it has neither acidic nor basic properties. An analysis of a sample, dried at  $106^{\circ}$ , indicates that the product obtained was not pure.

Analyses. Calc. for  $C_{18}H_{25}O_2N_3$ : C, 68.57; H, 7.94; N, 13.33. Found: C, 68.02; H, 8.39; N, 13.31, 13.36.

3-Hydroxy-1-fenchyl-5-phenyltriazole.—When 2.85 g. of benzoyl-fenchyl semicarbazide is boiled for one-half hour with 40 cc. of 30% potassium hydroxide, the triazole in the form of its potassium salt separates as an oil and redissolves on dilution. The triazole is liberated with hydrochloric acid and extracted with ether. It is readily soluble in water, alcohol or glacial acetic acid, slightly soluble in acetic ether or benzene, and insoluble in the other common solvents. Recrystallized from 95% ethyl alcohol, the triazole forms thick, triangular plates, which soften at 230° and melt at 234° to a clear, light brown liquid.

Analyses. Calc. for  $C_{18}H_{23}ON_3$ : C, 72.73; H, 7.74; N, 14.14. Found: C, 72.57, 72.79, 72.60; H, 8.00, 8.06, 7.67; N, 14.36, 14.38.

 $\alpha$ -Phenylcarbamyl-fenchyl Semicarbazide,  $C_{10}H_{17}N(CONHC_6H_6)$ —NHCONH2.—A solution of 4 g. of fenchyl semicarbazide and 2.4 cc. of phenyl isocyanate in 80 cc. of dry benzene is refluxed on a water-bath for one hour. The urethan separates and is recrystallized from 95% ethyl alcohol in the form of thin, shaft-like plates with arched end-faces, melting to a clear liquid at 192°. Like the other carbamyl derivatives described in this paper, it has neither acidic nor basic properties.

Analyses. Calc. for  $C_{18}H_{26}O_2N_4$ : C, 65.45; H, 7.88; N, 16.97. Found: C, 65.33; H, 7.93; N, 17.23.

Carvomenthyl Semicarbazide.—This semicarbazide prepared from carvone semicarbazone, ¹⁰ is readily soluble in the common solvents with the exception of water, ether, and petroleum ether. It separates from ethyl acetate in thin plates melting with slow gas evolution at 126°.

Analyses. Calc. for C₁₁H₂₃ON₃: C, 61.97; H, 10.79; N, 19.72. Found: C, 62.06; H, 11.02; N, 19.98.

Carvone semicarbazone is obtained in a yield of 73% by adding 7 cc. of carvone in 25 cc. of ethyl alcohol to a solution of 5 g. of semicarbazide hydrochloride and 5 g. of anhydrous sodium acetate in 10 cc. of water. After 12 hours the semicarbazone is filtered off and washed with water, alcohol, and ether.

Carvomenthyl Semicarbazide Hydrochloride.—The hydrochloride separates from the reduction mixture of carvone semicarbazone on concentration. Recrystallized from 95% alcohol, it is obtained in the form of short needles that decompose at 186°. This salt is readily soluble in alcohol and water, and very difficultly soluble in the other common solvents.

Analyses. Calc. for C₁₁H₂₄ON₃Cl: N, 16.83; Cl, 14.23. Found: N, 17.13; Cl, 13.99.

Benzoyl-carvomenthyl Semicarbazide.—The procedure here is the same as in the case of the corresponding fenchyl compound, except that only 70 cc. of benzene is employed to 5 g. of the semicarbazide. When the reaction is completed, one-half of the solvent is distilled, and after the addition of 200 cc. of petroleum ether the mixture is

¹⁰ Rupe and Dorschky, Ber., 39, 2113 (1906).

refluxed for one hour. In this way the benzoyl compound is obtained in a suitable state for filtering. Recrystallized from glacial acetic acid containing a few drops of water, it melts to a clear liquid at 235°. It is either difficultly soluble or insoluble in the common solvents.

Analyses. Calc. for  $C_8H_{27}O_2N_3$ : C, 68.14; H, 8.51; N, 13.25. Found: C, 67.82; H, 8.70; N, 13.35.

3-Hydroxy-1-carvomenthyl-5-phenyltriazole.—This triazole, prepared in the usual way, can be isolated, in the form of an oil, by means of extraction with chloroform. When this oil is taken up in alcohol and diluted with water, the triazole separates in a crystalline form by allowing the solution to evaporate at room temperature. It has solubilities similar to those of the corresponding fenchyl triazole, and crystallizes from absolute alcohol in thin plates that begin to soften at 180°, and melt completely at 187°.

Analyses. Calc. for  $C_{18}H_{25}ON_3$ : C, 72.24; H, 8.36; N, 14.05. Found: C, 72.14; H, 8.63; N, 14.27.

 $\alpha$ -Phenylcarbamyl-carvomenthyl Semicarbazide, prepared in benzene solution under the same conditions as the corresponding fenchyl derivative is, after removal of the greater part of the solvent, refluxed with petroleum ether, filtered off, and recrystallized from acetic acid containing a few drops of water. It is thus obtained in clusters of radiating needles that begin to soften at 202°, and melt at 205° with gas evolution. This derivative is readily soluble in glacial acetic acid and difficultly soluble in other common solvents.

Analyses. Calc. for  $C_{18}H_{28}O_{2}N_{4}$ : C, 65.06; H, 8.43; N, 16.87. Found: C, 65.21; H, 8.79; N, 17.05.

The Action of Formaldehyde on Carvomenthyl Semicarbazide Hydrochloride.—When an aqueous solution of carvomenthyl semicarbazide is treated with an excess of formalin, a white crystalline product separates immediately that is very soluble in the common organic solvents with the exception of petroleum ether. Since no method of purifying this substance by recrystallization was found, the sample for analysis was thoroughly washed with water and dried at room temperature in a vacuum. It begins to decompose with evolution of ammonia at about 125° and melts with further decomposition at 150°. The analysis indicates that in the above reaction a molecule of water is split out between one molecule of formaldehyde and two molecules of the semicarbazide. A probable structure of this substance is, therefore,  $CH_2(N(NHCONH_2)C_{10}H_{19})_2$ ,

Analyses. Calc. for  $C_{23}H_{46}O_2N_6$ : C, 63.01; H, 10.50; N, 19.18. Found: C, 62.79; H, 10.21; N, 18.41.

Hexahydrophenyl Semicarbazide.—After the solution obtained in the reduction of hexanone semicarbazone has been concentrated and chilled, it hexahydrophenyl semicarbazide hydrochloride separates as large acicular crystals, or the free base may be precipitated with ammonia. The base is readily soluble in alcohol, slightly soluble in ethyl acetate or benzene, and difficultly soluble in the other common solvents. Recrystallized from 95% ethyl alcohol, as fine needles, it softens at 183° and decomposes at 185° with evolution of gas.

Analyses. Calc. for  $C_7H_{15}ON_3$ : C, 53.50; H, 9.55; N, 26.75. Found: C, 53.46; H, 9.85; N, 26.87.

The hydrochloride recrystallizes from alcohol in long, slender needles melting at 176° to 178°.

Analyses. Calc. for C₇H₁₆ON₃Cl: N, 21.70; Cl, 18.35. Found: N, 21.85; Cl, 18.53.

¹¹ Zelinsky, Ber., 30, 1541 (1897).

Benzoyl-hexahydrophenyl Semicarbazide.—The conditions employed in the preparation and isolation of benzoyl-carvomenthyl semicarbazide are followed in this preparation. This benzoyl derivative is readily soluble in glacial acetic acid, moderately soluble in alcohol, chloroform or acetone, and difficultly soluble in the other common solvents. It can be recrystallized from 95% acetic acid in the form of fine needles, which begin to soften at 260°, and melt with slow evolution of gas at 267°.

Analyses. Calc. for  $C_{14}H_{19}O_2N_3$ : C, 64.33; H, 7.33; N, 16.08. Found: C, 64.30; H, 7.61; N, 16.28.

3-Hydroxy-1-hexahydrophenyl-5-phenyltriazole.—This triazole is prepared and isolated as was the corresponding carvomenthyl compound. It is very soluble in chloroform, less soluble in alcohol, slightly soluble in ethyl acetate, and very difficultly soluble in the other common solvents. It separates from alcohol in radiating clusters of slender prisms with pyramidal end-faces, and melts to a light brown liquid at 232–234°.

Analyses. Calc. for  $C_{14}H_{17}ON_3$ : C, 69.13; H, 7.00; N, 17.28. Found: C, 69.15; H, 7.33; N, 17.23.

 $\alpha$ -Phenylcarbamyl-hexahydrophenyl Semicarbazide, prepared in benzene solution under conditions analogous to those for the corresponding carvomenthyl derivative, is recrystallized from 95% alcohol as short microscopic needles, which decompose with vigorous gas evolution at 236°. It is slightly soluble in ethyl acetate, chloroform, and acetone.

Analyses. Calc. for  $C_{14}H_{20}O_2N_4$ : C, 60.87; H, 7.25; N, 20.29. Found: C, 60.80; H, 7.55; N, 20.53.

Benzyl Semicarbazide.—Benzyl semicarbazide was originally prepared by Kessler and Rupe by reducing benzal semicarbazone with sodium amalgam.  12  It can be made in a simple way by catalytic reduction of a mixture of semicarbazide hydrochloride and benzaldehyde in molecular proportions. However, the yield under the conditions employed is only 50% of that calculated.

# isoPropyl, Bornyl, and Menthyl Semicarbazides13

Under the conditions given above for reducing acetone semicarbazone, only  $^{1}/_{30}$  as much platinum is required as recommended by Neighbors and Bailey, with a slight increase in yield of iso-propyl semicarbazide. In the isolation of this semicarbazide with chloroform, continuous extraction is recommended. Our method of reducing camphor semicarbazone gives a quantitative yield of bornyl semicarbazide and employs only one-third of the amount of platinum used by Miller and Bailey. In reducing menthone semicarbazone,  $^{1}/_{27}$  of the platinum employed by Clark and Bailey is used, and the time consumed in the process is appreciably shortened. Attention is directed to the fact that menthyl semicarbazide hydrochloride is difficultly soluble in the common solvents. It is, therefore, advisable at the end of the reduction to filter off the hydrochloride before breaking the colloid. Any dissolved menthyl semicarbazide is recovered in the usual way.

Benzoyl Menthyl Semicarbazide.—This benzoyl derivative has poor crystallizing properties. For analysis it was purified by precipitation from its alcoholic solution with ethyl acetate as a crystalline powder melting with gas evolution at 216°.

Analysis. Calc. for C₁₈H₂₇O₂N₈: N, 13.25. Found: N, 13.50.

 $\alpha$ -Phenylcarbamyl-menthyl Semicarbazide, prepared like the corresponding carvomenthyl compound, crystallizes from alcohol in clusters of radiating needles, which decompose at 184°.

¹² Ref. 4, p. 26.

¹⁸ Ref. 1, pp. 1559, 1563.

Analyses. Calc. for  $C_{18}H_{28}O_2N_4$ : C, 65.06; H, 8.43; N, 16.87. Found: C, 65.09; H, 8.55; N, 17.21.

# Summary

- 1. Conditions are given for obtaining good yields of hydro-aromatic semicarbazides by catalytic reduction of the corresponding semicarbazones.
- 2. The catalytic reduction of acetone semicarbazone to *iso*-propyl semicarbazide has been simplified.
- 3. It is made probable that for the first time a method of general application has been found in catalytic reduction for the conversion of semicarbazones to the corresponding semicarbazides.
- 4. Terpene semicarbazides being now readily available, a pharmacological study of the heterocyclic compounds that can be made from these should prove of interest.

# THE BEHAVIOR OF SEMICARBAZIDES AT ELEVATED TEMPERATURES

By E. J. Poth and J. R. Bailey Received August 8, 1923

#### Introduction

Hexahydrophenyl semicarbazide, described in the preceding article decomposes at elevated temperatures, forming dihexahydrophenyl carbazide (I), hexahydrophenyl urazole (II), and dihexahydrophenyl urazine (III),

substances described in the experimental part of this paper. It is evident that in the formation of I, a molecule of urea is split out between two molecules of the semicarbazide, and that II results from the interaction of this urea with a third molecule of the semicarbazide, while if the structure of our urazine is correctly interpreted by Formula III, its formation is entirely independent of the reactions involved in connection with I and II.

Pinner¹ studied the effect of heat on phenyl semicarbazide and reported that at a temperature of 160–170° there are given off carbon dioxide, carbon monoxide and benzene, while the nonvolatile residue consists of unchanged phenyl semicarbazide, phenyl urazole, and diphenyl urazine. In repeating the experiment of Pinner, we find that ammonia, nitrogen and carbon dioxide, but not carbon monoxide, are evolved. What is more important

¹ Pinner, Ber., 21, 1224 (1888).

is the proof that diphenyl carbazide2 is also formed, although its isolation and analysis here were not effected. Through the remarkable color reactions of this substance reported by Cazeneuve3 it can now be identified in the minutest traces and, furthermore, as observed by Skinner and Ruhemann, this carbazide imparts through atmospheric oxidation to ammonium hydroxide solution within a short time a deep red color due to the formation of the so-called diphenyl carbazone, 4 C₆H₅N=NCONHNH- $C_6H_5$ . We find that phenyl semicarbazide, on the other hand, imparts to ammonium hydroxide solution a vellow color and gives none of the Cazeneuve color reaction of the carbazide. That diphenyl carbazide is formed at least in small amount, even on fusion of phenyl semicarbazide, can be demonstrated in a simple way by heating a very small sample of the latter substance in an ordinary melting-point tube to liquefaction, then immediately removing the tube from the bath, and carrying out the color tests referred to above. As is evident from the following equations, the formation of diphenyl carbazide, as a decomposition product of phenyl semicarbazide, clears up the mechanism of the simultaneous formation here of phenyl urazole.

$$2 C_{6}H_{5}NHNHCONH_{2} + \delta = (C_{6}H_{6}NHNH)_{2}CO + CO(NH_{2})_{2}$$

$$N-C_{6}H_{5}$$

$$C_{6}H_{5}NHNHCONH_{2} + CO(NH_{2})_{2} = CO NH + 2NH_{3}$$
(2)

The structure of Pinner's so-called diphenyl urazine was first correctly interpreted by  $Heller^5$  as  $C_6H_5-N$ —NH-CO and this formula has

been confirmed by the work of other investigators.6

As might be expected, dihexahydrophenyl carbazide does not give color reactions analogous to diphenyl carbazide. An explanation of this difference in behavior of the two carbazides is evident from the following considerations. All the color reactions of diphenyl carbazide depend primarily on the oxidation of this hydrazo body to a mixed hydrazo-azo compound containing the group, —N=N—CO—NHNH—. In the hydrazo complex of this group the imido hydrogens are replaceable by metals with the formation of colored salts that possess the unusual property of being soluble in organic solvents. On the other hand, dihexahydrophenyl carbazide contains the group CO(NHNHCH=)2, and it is well known that the stable oxidation product expected here would be of hydrazono and not azo structure.

It is probable that the system, 2 mols. of semicarbazide  $\stackrel{\frown}{}$  1 mol. of carbazide + 1 mol. of urea, represents a reversible reaction. In conformity with this view is the observation of Skinner and Ruhemann⁸ that phenyl semicarbazide is formed on heating a mixture of diphenyl carbazide and urea. In the case of the phenyl compounds the equilibrium shifts to the left, while with hexahydrophenyl compounds it shifts to the right, so that in the latter case conditions have been established for obtaining a fairly good yield of carbazide by heating the semicarbazide.

The very unexpected observation was made that hexahydrophenyl semicarbazide on heating with urethan forms the carbazide in good yield. Apparently, the action of the urethane is either catalytic or, what is more probable, the urethan simply exerts a solvent action, causing a liquefaction of the semicarbazide at a temperature lower than its melting point. This latter view is in accordance with our observation that protracted heating of the semicarbazide melt or the urethan-semicarbazide melt has a marked influence in decreasing the yield of carbazide, due probably to its gradual decomposition at elevated temperatures. This method of preparing dihexahydrophenyl carbazide, applied to *i*-propyl and phenyl semicarbazides, showed that here urethan has no effect on the carbazide formation, at least under the conditions of our experiments.

# Experimental Part

The Decomposition of Hexahydrophenyl Semicarbazide at Elevated Temperatures.—The semicarbazide, heated for 11/2 hours at 180-185°, decomposes, giving a strong odor of ammonia and an aromatic odor resembling cyclohexanol. The melt, of a slightly yellow color, is extracted with 50 cc. of boiling water and filtered. From the filtrate there separates a white crystalline product, which is filtered off, and the filtrate is again used for extracting the residue. In all, three extractions are made with the same solution. The water-soluble material is leached out with a little chloroform to remove carbazide and urazine present only in small amounts, the residue dissolved in ammonia, and the urazole precipitated from the filtered solution with acetic acid. For further purification it is recrystallized from water. The yield of urazole is about 13.8% of that calculated theoretically. The water-insoluble product obtained above dissolves in ammonia, thus showing the absence of unchanged semicarbazide, and reprecipitates with acetic acid. It is purified by recrystallization from alcohol. The yield of urazine is about 34%. The carbazide, which under the above conditions is formed in very small amount, is dissolved in acetic acid and reprecipitated with ammonia with subsequent recrystallizations from water and acetic ether. Complete analyses of the above products agree closely in each case with the formula assigned.

⁸ Skinner and Ruhemann, Ber., 20, 3373 (1887).

If the semicarbazide is quickly heated up to  $200^{\circ}$ , 12 minutes being consumed in the operation, all the water-soluble material dissolves in dil. hydrochloric acid, thus showing the absence of urazole, and the carbazide is obtained from the acid solution by precipitation with ammonia in a yield of 41%. As the water-insoluble material is completely soluble in acid, it contains no urazine, but is unchanged semicarbazide. The amount recovered amounted to 19.5% of that originally used in the experiment.

Dihexahydrophenyl Carbazide.—The carbazide is readily soluble in cold chloroform or alcohol. Recrystallized from water, it is obtained in plates that melt at 187°. Acetic ether is also well adapted for recrystallizing the carbazide, which is difficultly soluble in benzene and sparingly soluble in ether. This substance acts as a strong reducing agent.

Analyses. Calc. for  $C_{13}H_{26}ON_4$ : C, 61.42; H, 10.23; N, 22.05. Found: C, 61.38; H, 10.34; N, 22.19.

Dihexahydrophenyl carbazide hydrochloride separates on dissolving the carbazide in methyl alcoholic hydrochloric acid in the form of thin plates, melting with gas evolution at 217°.

Analyses. Calc. for C₁₃H₂₈ON₄Cl₂: N, 17.12; Cl, 21.47. Found: N, 17.18; Cl, 21.76.

The most satisfactory method of preparing dihexahydrophenyl carbazide from the corresponding semicarbazide is to heat the latter mixed with 1/2 its weight of urethan at 160° until liquefaction ensues and then maintain a temperature of 150° for 15 minutes. In this way an almost completely water-soluble melt is obtained which, worked up in the way described, gives a yield of 73% of carbazide. In an experiment where the mixture of semicarbazide and urethan was heated at 165° for  $1^1/2$  hours, only a 20% yield of carbazide was obtained.

Phenyl semicarbazide and i-propyl semicarbazide, heated with urethan under conditions similar to those employed in the case of hexahydrophenyl semicarbazide do not give the corresponding carbazides.

Hexahydrophenyl Urazole, or 3,5-Dihydroxy-1-Hexahydrophenyl Triazole.—The urazole is readily soluble in hot water and crystallizes on cooling in characteristic, thin, prismatic plates which melt at 271°. It is readily soluble in alcohol and sparingly soluble in the other common organic solvents. It does not give a color reaction with ferric chloride, shows an acid reaction to litmus, and acts as a strong reducing agent.

Analyses. Calc. for  $C_8H_{18}O_2N_3$ : C, 52.46; H, 7.10; N, 22.95. Found: C, 52.71; H, 7.25; N, 23.12.

The urazole is obtained in a yield of 74.5% by heating hexahydrophenyl semicarbazide and urea in molecular proportions. The mixture in a glycerol bath at 200° quickly liquefies with vigorous evolution of gas with the melt at a temperature of 150°. After 10 minutes the melt at a temperature of 190° becomes solid only to liquefy again after a few minutes. Toward the end of the operation, which consumes ½ hour in all, the reaction mixture again becomes solid. During the entire operation the mixture is stirred. The urazole prepared in this way acquires its ready solubility in hot water only after it has been dissolved in ammonium hydroxide and reprecipitated with acetic acid. The above method of preparing urazoles was originally used by Pinner⁹ in the preparation of the corresponding phenyl urazole from phenyl semicarbazide.

Dihexahydrophenyl Urazine or 3,6-Dihydroxy-1,4-dihexahydrophenyl-1,2,4,5-Tetrazine.—The urazine is very soluble in chloroform or alcohol, more difficultly soluble

⁹ Ref. 1, p. 1220.

in water, acetic ether, or benzene, and very difficultly soluble in ether. It can be recrystallized from acetic ether in the form of a network of fine needles, or from alcohol in slender prisms, which begin to soften at 187° and melt at 197°. Compared with the corresponding urazole, the urazine is less soluble in water and alcohol and more soluble in chloroform, benzene, and acetic ether. It acts as a strong reducing agent and gives no color reaction with ferric chloride.

Analyses. Calc. for  $C_{14}H_{24}O_2N_4$ : C, 60.00; H, 8.57; N, 20.00. Found: C, 60.32; H, 8.81; N, 20.03.

Dihexahydrophenyl carbazide and urea, heated in molecular proportions at 180° for 30 minutes, do not yield urazine, at least not in an amount sufficient for identification. This is in conformity with the structural formulas assigned here.

The most satisfactory method of preparing dihexahydrophenyl urazine is through the decomposition of the hydrochloride of the corresponding semicarbazide. When this salt is heated for  $^{1}/_{2}$  hour at 200–210°, there is very little evolution of gas and the product without liquefying becomes viscous. For isolation of the urazine, the ammonium chloride, along with a small amount of carbazide, is leached out with boiling water, the residue dissolved in ammonium hydroxide, the solution filtered from tarry matter, and the urazine precipitated with acetic acid. This method of preparation gives a 70% yield of urazine.

The Gaseous Products Evolved on Heating Phenyl Semicarbazide.—As stated above, Pinner found among the decomposition products of phenyl semicarbazide, ammonia, carbon dioxide and carbon monoxide. In testing for carbon dioxide, it should be observed that this combines with the ammonia given off to form ammonium carbamate. To determine whether carbon monoxide is formed in the decomposition of the semicarbazide, 5 g. was heated at 109° for 5 hours in an atmosphere of carbon dioxide. The gas, collected in the usual way over 30% sodium hydroxide, measured 21.5 cc. at 26° and 746 mm. No reduction of this volume was effected by scrubbing the gas with cuprous chloride, which proves quite conclusively that nitrogen and not carbon monoxide was the gas under investigation.

# Summary

- 1. Diphenyl carbazide is formed together with phenyl urazole and diphenyl urazine when phenyl semicarbazide is heated. The carbazide was identified by its characteristic color reactions.
- 2. Hexahydrophenyl semicarbazide, like phenyl semicarbazide, decomposes when heated with the formation of the corresponding carbazide, urazole and urazine. These were all isolated and analyzed.
- 3. Special methods are given in each case for the preparation in good yields of hexahydrophenyl urazole, dihexahydrophenyl carbazide and dihexahydrophenyl urazine from hexahydrophenyl semicarbazide.

AUSTIN, TEXAS

$$RAs(ONa)_2 + CICH_2COONa \longrightarrow RAs = O + NaCl^9$$
 (4)

led to the supposition that it would react with sodium arsenite as well. It has now been found that sodium chloro-acetate can be converted quantitatively into arsono-acetic acid merely by allowing it to react in aqueous solution for two hours with a 100% excess of sodium arsenite. On account of the extreme solubility of the product, it is best isolated as the barium salt.

To prepare arseno-acetic acid, barium arsono-acetate is stirred with hot aqueous sodium sulfate, barium sulfate filtered off, and the cold filtrate treated with sulfuric acid and sodium hypophosphite. On long standing in the cold there results an excellent yield of arseno compound. If the reaction mixture is heated even at a temperature as low as 50°, there is decomposition with formation of inorganic arsenic and the product is badly contaminated with polyarsenide as a result. When pure, arseno-acetic acid consists of yellow needles, which decompose above 200° without melting, and are insoluble in water and common organic solvents, but readily soluble in pyridine and in dilute aqueous alkali hydroxides and carbonates.

Aromatic polyarsenides have been prepared by the simultaneous reduction of aromatic arsonic acids and arsenious acid. ¹⁰ In a similar manner reduction of one molecular equivalent of arsenic trioxide and two of arsonoacetic acid leads to the formation of the bright vermilion-red polyarsenide, tetra-arseno-acetic acid:

OAs 
$$H_2O_3As \cdot CH_2 \cdot COOH$$
 As=As·CH₂·COOH  
OAs  $H_2O_3As \cdot CH_2 \cdot COOH$   $+ 7 H_3PO_2 \rightarrow \Big|$   $+ 7 H_3PO_3 + 2 H_2O$  (5)  
OAs  $H_2O_3As \cdot CH_2 \cdot COOH$ 

In solubility and in behavior toward heat this compound closely resembles arseno-acetic acid.

The sodium salts of arseno-acetic and tetra-arseno-acetic acids are precipitated from aqueous solution by addition of alcohol. Pharmacological tests on these salts are being performed by Professor H. G. Barbour of the University of Louisville, who will publish the results elsewhere.

The preparation of homologs and derivatives of the substances described in this communication, including aliphatic-aromatic arseno compounds, is now in progress. A similar series derived from the chlorohydrins will also be made.

# Experimental Part

Arsono-acetic Acid, ¹¹ H₂O₃As CH₂ COOH.—The second reference contains a description of the preparation of arsono-acetic acid from sodium arsenite and sodium chloro-acetate. Using the reagents in the proportion stated in this patent only one-third of the chloro-acetic acid and one-half of the arsenic trioxide are converted into calcium arsono-acetate. The melting point of the free acid is given as 152°, and of the ethyl ester as 94–95°.

The author of the present paper performed his original experiment with sodium arsenite and sodium chloro-acetate in September, 1920, and this method of synthesis was indicated in an application filed with the Research Fellowship Board, National Research Council, in February, 1921.

A solution of 99 g. of arsenic trioxide and 160 g. of sodium hydroxide in 300 cc. of water is cooled to room temperature; of this a lcc. portion is then titrated with iodine according to the common volumetric method for the determination of arsenic. In the sodium arsenite solution is dissolved 47.25 g. of chloro-acetic acid (50% of the calculated quantity) and the strongly exothermic reaction begins. At the end of two hours a second lcc. portion of the reaction mixture is removed and titrated. The result indicates that approximately one-half of the sodium arsenite has disappeared. The solution is acidified with glacial acetic acid, avoiding an excess, and cooled. Most of the remaining arsenic trioxide precipitates and is filtered off. The filtrate is poured into a solution containing 185 g. of crystallized barium chloride in 500 cc. of warm water. Barium arsono-acetate, Ba(OOC.CH₂.AsO₃Ba)₂.6¹/₂H₂O, immediately forms as a white, finely divided precipitate. It is filtered on a 15cm. Büchner funnel, washed thoroughly with water and dried on plates. The precipitated product is quite pure, but it can be recrystallized from a large volume of boiling water, in which it is sparingly soluble, as fine, feathery, colorless needles. The yield is almost quantitative (between 220 and 230 g.).

Analyses. Subs., 0.1542, 0.3587: loss at  $110^{\circ}$ , 0.0203, 0.0464. Calc. for  $C_4H_4O_{16}-As_2Ba_5.6^{1}/_2H_2O$ :  $H_2O$ , 13.13. Found: 13.16, 12.93.

Dried subs., 0.2789, 0.1410: 18.5, 9.3 cc. iodine (1 cc. = 0.00293 g. As). Dried subs., 0.2151, 0.3594: BaSO₄, 0.1922, 0.3226. Calc. for  $C_4H_4O_{10}As_2Ba_3$ : As, 19.38; Ba, 53.23. Found: As, 19.43, 19.32; Ba, 52.59, 52.82.

The necessity for using an excess of sodium arsenite is shown by an experiment with reagents as indicated theoretically in Equation 1. After the reaction mixture had stood for 4 hours it was demonstrated by iodine titration that 49% of the original sodium arsenite remained. No change was produced by 18 hours' refluxing. At this point one additional molecular equivalent of chloro-acetic acid and of sodium hydroxide were dissolved in the solution. After 4 additional hours of refluxing, 46% of the sodium arsenite had still failed to react.

Sodium arsono-acetate is prepared by adding 89.1 g. of barium arsono-acetate to a solution of 42.5 g. of anhydrous sodium sulfate in 200 cc. of hot water. The mixture is digested for 1 hour at 100° and frequently stirred. The barium sulfate is then filtered off and the filtrate concentrated on the steam-bath. Sodium arsono-acetate is obtained in several fractions having a combined weight of 47.8 g. (calc., 50.0 g.). This product contains a slight impurity of sodium sulfate, from which it is completely freed by one or two recrystallizations. In final form sodium arsono-acetate is a white, microcrystalline

¹¹ Ref. 8. Huisman, Callsen and Grüttefien, U. S. pat. 1,445,685, Feb. 20, 1923;

IV. 721.

powder that readily dissolves in cold water to give a solution which reacts alkaline to litmus.

Analyses. Subs., 0.5544: loss at 110°, 0.0000. Subs., 0.1913, 0.1389: 19.3, 14.0 cc. iodine (1 cc. = 0.00293 g. As). Subs., 0.1729, 0.1729: Na₂SO₄, 0.1455, 0.1491. Calc. for C₂H₂O₅AsNa₃: As, 30.00; Na, 27.60. Found: As, 29.56, 29.53; Na, 27.24, 27.92.

Isolation of free arsono-acetic acid from the original reaction mixture after precipitation of the excess of arsenic trioxide is not very satisfactory, since the acid is separated from the various inorganic by-products of the reaction only by a long and inefficient process of fractional crystallization in which the solvent is gradually changed from water to alcohol. The acid is more readily obtained from the barium salt. A mixture of 22.5 g. of powdered barium arsono-acetate and 100 cc. of water containing 5 cc. of sulfuric acid (d., 1.84) is mechanically stirred at room temperature for several hours. Barium sulfate is removed by filtration and the filtrate concentrated in a vacuum over sulfuric acid in the cold. At very small volume crystallization commences. Twentyfive cc. of absolute alcohol is stirred with the mixture of crystals and viscous liquor and the insoluble, inorganic, arsenic containing material filtered off. To the filtrate 25 cc. of ligroin is added and the mixture concentrated at room temperature as before. Arsono-acetic acid now crystallizes, is filtered off, washed with ligroin and dried on a tile. The product consists of colorless, shining plates; m. p., 152° (loss of gas). It is very soluble in water and alcohol, sparingly soluble in hot glacial acetic acid, practically insoluble in ligroin, benzene, acetone, chloroform or ethyl acetate.

Analyses. Subs., 0.1778, 0.1475: 24.5, 20.3 cc. iodine (1 cc. = 0.00293 g. As). Calc. for  $C_2H_5O_5As$ : As, 40.76. Found: 40.37, 40.32.

Heating during the preparation of arsono-acetic acid as outlined above is inadvisable. Apparently the arsono group is split off very easily when arsono-acetic acid is in hot mineral acid solution and, unless heating is avoided, the isolation of the acid becomes difficult or impossible.

Arseno-acetic Acid, HOOC·CH₂·As=As·CH₂·COOH.—A solution of 12.5 g. of sodium arsono-acetate and 30 g. of sodium hypophosphite (NaH₂PO₂·H₂O) in 150 cc. of 15% sulfuric acid is allowed to stand in the cold. After two days the yellow precipitate is filtered off, washed several times with water and dried in a vacuum over sulfuric acid. When dried in air the product darkens slightly, due undoubtedly to oxidation. The filtrate is allowed to stand as before and, after two additional two-day periods, the reaction is practically complete; total yield, 6.2 g. (calc., 6.7 g.). Arseno-acetic acid forms minute yellow needles which begin to decompose at about 205°, but do not melt below 260°. It is insoluble in water and common organic solvents, but readily soluble in pyridine, dil. sodium hydroxide, and dil. sodium carbonate solutions. Usually at least one of the fractions will be found to be analytically pure and the rest nearly so.

Analyses. Subs., 0.1023, 0.1444: 19.5, 27.5 cc. iodine (1 cc. = 0.00293 g. As). Calc. for  $C_4H_6O_4As_2$ : As, 55.96. Found: 55.86, 55.80.

For the preparation of arseno-acetic acid on a larger scale it is convenient to warm the wet, freshly filtered barium arsono-acetate prepared as described above with sodium sulfate solution and to treat the filtrate from barium sulfate with sulfuric acid and sodium hypophosphite in the cold. Yields of 80–90% calculated from the chloro-acetic acid are obtained. In one run the reaction mixture was heated at 50–55° and the reduction completed in 8 hours. The orange-colored product was found to contain over 70% of arsenic. Evidently the decomposition already noted had taken place and simultaneous reduction of the arsonic acid with an inorganic arsenic compound gave a mixture composed principally of polyarsenide. In the cold this formation of inorganic arsenic is

largely prevented, but even at this low temperature later fractions of material may contain a small quantity of tetra-arseno-acetic acid.

A solution of 3.35 g. of arseno-acetic acid in 25 cc. of 5% sodium hydroxide is filtered and 75 cc. of 95% alcohol added. A yellow oil precipitates which, after several hours' standing, crystallizes in rosets composed of very fine needles. These are filtered off, washed repeatedly with 95% alcohol and dried in a vacuum over sulfuric acid; weight, 3.7 g. The salt is then in the form of a light yellow-brown powder which retains some solvent, probably alcohol, and must be dried to constant weight at  $110^\circ$  before analysis. Disodium arseno-acetate is readily soluble in water, giving a clear yellow solution which reacts slightly alkaline to litmus.

Analyses. Subs., 0.1257, 0.2081: 20.5, 34.0 cc. iodine (1 cc. = 0.00293 g. As). Subs., 0.1665, 0.2201: Na₂SO₄, 0.0768, 0.1045. Calc. for C₄H₄O₄As₂Na₂: As, 48.08, Na, 14.74. Found: As, 47.78, 47.87; Na, 14.93, 15.37.

Tetra-arseno-acetic Acid, HOOC·CH₂·As=As-As=As·CH₂·COOH,—Arsonoacetic acid is prepared from sodium arsenite and sodium chloro-acetate in a run just half the size of that described above. As soon as the reaction is complete, 150 g. of sulfuric acid (d., 1.84) and 100 g. of sodium hypophosphite are dissolved in the solution. After three hours a mixture of arsenic trioxide and sodium sulfate containing a little highlycolored organic arsenic compound is filtered off, and the filtrate is allowed to stand in the cold. A bright red precipitate gradually forms, which is filtered off at 3- to 4-day intervals, washed several times with water and dried in a vacuum over sulfuric acid. Drying in air causes the exposed surface to blacken. Altogether, five fractions are obtained, most of which are fairly pure; total yield, 25.6 g. Heating increases the rate of reaction but tends to produce an impure product. Tetra-arseno-acetic acid is a bright vermilion-red, microcrystalline powder, which begins to decompose at about 180°, but does not melt below 250°. The solubilities are closely similar to those of arseno-acetic acid.

Analyses. Subs., 0.1360, 0.1926: 33.1, 46.9 cc. iodine (1 cc. = 0.00293 g. As). Calc. for  $C_4H_6O_4As_4$ : As, 71.77. Found: 71.31, 71.37.

Seven g. of tetra-arseno-acetic acid is dissolved in 50 cc. of 5% sodium hydroxide solution. On addition of 50 cc. of 95% alcohol, a thick, dark oil is precipitated. The dilute alcohol is decanted, the residue redissolved in 50 cc. of water and an equal volume of 95% alcohol added. The precipitate can now usually be obtained crystalline. It is filtered off, washed with 50% alcohol and dried in a vacuum over sulfuric acid; weight, 6.4 g. Monosodium tetra-arseno-acetate is a red-brown powder which is considerably less soluble in water than disodium arseno-acetate. The solution is dark colored and reacts practically neutral to litmus, with possibly a slight tendency toward alkalinity. It is noteworthy that a monosodium salt is formed in spite of use of an excess of sodium hydroxide.

Analyses. Subs., 0.1090, 0.1232: 25.4, 28.8 cc. iodine (1 cc. = 0.00293 g. As). Subs., 0.1784, 0.1578: Na₂SO₄, 0.0312, 0.0286. Calc. for C₄H₅O₄As₄Na: As, 68.18; Na, 5.23. Found: As, 68.28, 68.49; Na, 5.66, 5.87.

# Summary

- 1. Action of a 100% excess of sodium arsenite on sodium chloro-acetate gives a quantitative yield of arsono-acetic acid.
- 2. Reduction of arsono-acetic acid with hypophosphorous acid produces arseno-acetic acid.
  - 3. By simultaneous reduction of one molecular equivalent of arsenic

trioxide and two of arsono-acetic acid the polyarsenide, tetra-arseno-acetic acid. is obtained.

- 4. Water-soluble sodium salts of the above acids are readily prepared.
- 5. Analogous series derived from various halogen acids and halohydrins are now being synthesized in this Laboratory.

# THE USE OF PLATINUM OXIDE AS A CATALYST IN THE REDUCTION OF ORGANIC COMPOUNDS. IV. REDUCTION OF FURFURAL AND ITS DERIVATIVES:

By W. E. Kaufmann² with Roger Adams Received August 15, 1923

The commercial development of furfural during recent years and its remarkable cheapness has led to many investigations for new uses. This communication describes the results obtained on the catalytic reduction of furfural and a number of its simple derivatives. The reduction is of interest not only because the products might be of practical importance, but also because there has been very little work done on the reduction of compounds of the furane series. Moreover, furfural itself is a different type of aldehyde from those which have thus far been reduced with the use of platinum oxide³ as a catalyst and ferrous chloride as an activating agent.

The first work on the reduction of furfural was published in 1906 by Padoa and Ponti⁴ who passed the vapors of furfural with hydrogen over a nickel catalyst at 190°. The primary product of the reduction was furyl alcohol. Further reduction always took place and from the mixture of reaction products it was possible to isolate methyl-2-furane, methyl-2-tetrahydrofurane and pentanol-2. It may thus be seen that rupture of the ring took place during reduction, though to only a very slight extent. The same authors reported that when they used a temperature of 270° the decomposition yielded in addition furane and carbon monoxide.

Law⁵ studied the electrolytic reduction of furfural in the presence of alkali and acid but, with the exception of a small amount of furyl alcohol when the acid solution was used, only resins were obtained.

Pringsheim and Noth⁶ reduced furfural by passing the vapors with hydrogen over

¹ Part of the chloroplatinic acid used in this investigation was purchased with the aid of a grant from the Bache Fund of the National Academy of Sciences. For this aid the authors are greatly indebted.

² This communication is an abstract of a thesis submitted by W. E. Kaufmann in partial fulfilment of the requirements for the Degree of Doctor of Philosophy in Chemistry at the University of Illinois.

⁶ Pringsheim and Noth, Ber., 53, 114 (1920).

iron as a catalyst at 200°. They observed the formation of the same products reported by Padoa and Ponti when nickel was used and in addition, furane and dihydrofurane. They concluded that in the reduction of furfural (1) the aldehyde group can be reduced to a methyl, (2) the aldehyde group may be eliminated entirely with the formation of furane or hydrogenated furanes, and finally (3) the ring is ruptured and the resulting products are hydrogenated.

More recently, the reduction of furfural has been undertaken by Wienhaus, using charcoal impregnated with palladium chloride solution as a catalyst and reducing with hydrogen at ordinary temperatures and one atmosphere pressure. The reduction was carried out in the presence of water as well as without any solvent. There was thus obtained as a chief product tetrahydrofuryl alcohol, but in addition high-boiling products which the author supposed to be bimolecular compounds similar to those reported by Skita in the reduction of citral. These, however, were not investigated. The reaction was apparently quite unsatisfactory since it required 285 hours' time with 10 additions of fresh catalyst for the reduction of 48 g. of furfural. By the reduction of furyl alcohol the same author obtained a reaction mixture similar to that from furfural itself, thus indicating that furyl alcohol was the primary reduction product.

The reduction of furane and other derivatives besides furfural has been less extensively studied. Bourgignon's reported the reduction of furane with hydrogen and a nickel catalyst at 170°. A large portion of the furane was recovered unchanged and, in addition, a small amount of tetrahydrofurane and n-butyl alcohol.

Douris's reduced furyl ethyl carbinol with hydrogen and nickel catalyst at 175° and obtained as the chief product ethyl tetrahydrofuryl carbinol. As by-products were formed propyl-2-tetrahydrofurane, propyl-butyl ether, propyl-butadienyl ether, dipropyl ketone and a sirup which was not purified but which the author believed to be a glycol.

Yoder and Tollens¹⁰ showed that by the action of sodium amalgam, pyromucic acid was not reduced. On the other hand, with this same reagent Hill and Wheeler¹¹ reduced furane-2,5-dicarboxylic acid readily to the tetrahydro derivative.

 $\beta\textsc{-Furyl-acrylic}$  acid has been reduced by Markwald with phosphorus and hydriodic acid to pimelic acid.  12 

Semler¹³ reduced fural-acetophenone with sodium and alcohol to furyl-phenyl-propane. Apparently no reduction of the furane ring took place in this reaction.

Catalytic reduction with platinum or palladium catalyst has been used on a number of furfural derivatives. Wienhaus and Sorge¹⁴ reduced pyromucic acid in the presence of platinum chloride and gum arabic to a product which they identified as tetrahydropyromucic acid. The reduction, just as with furfural itself, took place only very slowly and no yield was reported. Asahina and Shibata, ¹⁵ by means of hydrogen and platinum black in acetic acid, reduced methyl  $\beta$ -furyl-propionate to methyl  $\beta$ -tetrahydrofuryl-propionate. Windaus and Dalmer, ¹⁶ using hydrogen and platinum black, reduced  $\beta$ -furyl acrylic acid to  $\beta$ -tetrahydrofuryl-propionic acid. Finally, Bargellini and Marte-

giani¹⁷ reduced fural-acetophenone with hydrogen and platinum or palladium black. They reported that only the ethylene double bond in the side chain was hydrogenated. Since quite different results were obtained in this investigation it may be mentioned that the method of these authors consisted merely in bubbling the hydrogen through a warm solution of the substance in alcohol without using pressure.

In this investigation the reduction of furfural, fural-acetone, fural-acetophenone, furoin, pyromucic acid, ethyl pyromucate and  $\beta$ -furyl-acrylic acid was studied. Alcohol was used as a solvent, and the catalyst employed was the platinum oxide³ recently described and shown to be so active for the reduction of various types of organic compounds.

No difficulty was observed in the reduction of furfural when the proper conditions were used. The first experiments in this investigation consisted in determining the nature of the product obtained by the absorption of 1 molecular equivalent of hydrogen. It was found that a quantitative yield of furyl alcohol resulted, thus establishing without question that the initial point of attack of the hydrogen was the aldehyde group and that no other part of the molecule reacted until after the aldehyde group was completely reduced.

The other experiments were carried out to determine the nature of the products of reduction when as much hydrogen was absorbed as would be taken up. Instead of the absorption of three molecular equivalents of hydrogen, as would be expected if merely the aldehyde and the two double bonds of the furane ring were reduced, it was always found that more was absorbed, 3.2 to 4.3 molecular equivalents, the amount depending generally upon the type of catalyst used, the mode of reactivation and the length of time the reactions were allowed to proceed at the very end of the absorption. The reaction mixture obtained by the complete reduction of 12 runs of 50 g. each of furfural was worked up at one time. After distillation of the alcohol a brown oil resulted which weighed approximately 600 g., showing that no very volatile materials had been produced. The mixture was first carefully fractionated a number of times under diminished pressure until it separated into four main fractions, each boiling within a few degrees. These fractions were then redistilled independently and constant boiling products isolated. The first substance boiled at 137-139° at 751 mm. and proved by analysis and by its physical constants to be n-amyl alcohol. The second substance boiled at 176-177° at 751 mm. and was pure tetrahydrofuryl alcohol. Its constants agreed exactly with those described in the literature for this substance. The third substance boiled at 210.5-211.5° at 751 mm. By analysis and its formation of a diacetate it was shown to be a pentane glycol. It undoubtedly was pentanediol-1,2, a substance which has not been previously described. The fourth substance boiled at 239-241° at 751 mm. and was shown to be pentanediol-1,5. By analysis and by a comparison of its physical constants and those of its diacetate with

17 Bargellini and Martegiani, Gazz. chim. ital., 42, [2] 417, 427 (1912).

the constants given in the literature for these substances, the compound was identified. Practically no residue was obtained. The four main fractions, from the lowest to the highest boiling weighed, respectively, 60 g., 222 g., 131 g. and 51 g. These figures do not represent the weight of pure materials obtained, but give some idea of the approximate proportion of each compound present in the mixture for one set of runs. The mechanism for the formation of these various products is best illustrated in the following chart.

Since the first molecular equivalent of hydrogen absorbed by the furfural gave a quantitative yield of furyl alcohol (I), it is obvious that the reduction of furyl alcohol itself must take place in a number of different ways. The main reaction is obviously simple hydrogenation of the double bonds in the furane ring with the formation of the tetrahydrofuryl alcohol (II). On the other hand, part of the reduction takes place between the oxygen of the furane and one or the other of the two carbons to which it is attached. By

the reduction at Point A in Formula I, an intermediate substance is obtained which would immediately be reduced to pentanediol-1,2 (III). If the reduction took place at Point B in Formula I, an intermediate product would be formed which would reduce immediately to pentanediol-1,5 (IV). The *n*-amyl alcohol (V) may be formed either by the subsequent reduction of one of the glycols, possibly the pentanediol-1,2 or more probably by the direct reduction and elimination of oxygen from the furane ring of the furyl alcohol with immediate reduction of the intermediate product. The formation of the glycols or *n*-amyl alcohol certainly does not take place through the tetrahydrofuryl alcohol as an intermediate, since pure tetrahydrofuryl alcohol could not be reduced to the slightest extent under the conditions used for the reduction of furfural.

A comparison of the rupture of the furane ring by this reduction method and those previously employed is of interest. The opening of the furane

ring at ordinary temperatures, as found in this investigation, is apparently much greater in amount than that which takes place by the use of other catalytic methods where high temperatures are employed. Moreover, the high temperature catalytic reductions gave a larger number of products and the number apparently varied with slight changes in conditions. Only the same four products of reaction were ever obtained in this work.

The character of the catalyst had a marked effect upon the speed of the reduction of the furfural. The results of the different experiments were of such general interest that a detailed discussion of the catalyst is necessary. In the previous paper it was shown that the platinum oxide made from spectroscopically pure chloroplatinic acid was a very inefficient catalyst toward the reduction of benzaldehyde. This same thing has been observed in the reduction of furfural; only by reactivation of the catalyst could the reduction be carried out at all, and then only very slowly. The presence of small amounts of ferrous chloride, however, caused the same marked increase in the activity of the catalyst as was shown in the case of benzaldehyde and heptaldehyde. In standard experiments on the reduction of these latter compounds, an increase in the amount of ferrous chloride, without changing the quantities of the other reagents, had practically no effect upon the speed of reduction after a certain minimum quantity had been added. In the reduction of furfural, however, this was not the case. With increasing amounts of ferrous chloride the speed of reduction increased to a point beyond which it decreased rapidly. No explanation of this fact has yet been found and a further study of the effect of ferrous chloride is necessary.

In the experiments to determine these facts, 25 g. of furfural, 75 cc. of alcohol and 0.5 g. of catalyst (sp. p.)18 were used with various quantities of ferrous chloride. The most effective amount tried was 1.2 cc. of 0.1 M ferrous chloride. The results obtained using twice these amounts of reagents, namely 50 g. of furfural, 150 cc. of alcohol and 1 g. of platinum oxide with various amounts of ferrous chloride, were surprising. It was expected that for such a run as this, 2.4 cc. of 0.1 M ferrous chloride would activate the platinum so as to cause the reduction of this larger quantity to take place with the same speed as shown in the smaller run. This, however, was not the case. With 2.4 cc. of ferrous chloride, the reduction of the furfural did not take place as rapidly as in the smaller runs. On the other hand, if only 1.2 cc. of ferrous chloride was used, the same as in the smaller runs, the reduction proceeded just as rapidly. These results indicate that a certain amount of ferrous chloride can just as effectively activate small or large amounts of platinum catalyst. Further study of this relationship with other aldehydes is being made.

With these data available, it is not surprising that in a series of runs of

^{18 &}quot;Sp. p." is an abbreviation indicating that the catalyst was prepared from spectroscopically pure chloroplatinic acid.

25 g. of furfural, 75 cc. of alcohol, 0.5 g. of catalyst (sp. p.) and 1.2 cc. of 0.1 M ferrous chloride, it was found that when, after complete reduction of the furfural, the liquid was decanted and fresh quantities of furfural and alcohol were added, the addition of more ferrous chloride in the second run was unnecessary. In fact, when ferrous chloride was added, the reduction of the second portion of aldehyde was slower than the reduction of the first; without addition of ferrous chloride to the second run, the reduction was just as rapid as in the first run. The same conditions held true with the third run, using the same platinum catalyst. When ferrous chloride was added in the first run, also in the second and still again in the third, the reduction was much slower in the third than in the second run and it was quite obvious that the catalyst was being gradually rendered ineffective by further additions of ferrous chloride. On the other hand, with no further addition of ferrous chloride after the first run, the platinum catalyst proved to be practically as effective in the second, third, fourth and fifth runs. In all these experiments the amount of activity restored to the catalyst after reactivation with air or oxygen was proportional to that activity held initially by the catalyst in the presence of any given quantity of ferrous chlorahi

It is noticeable that in these series of reductions where further addition of ferrous chloride tended to cause a diminution in the speed of reduction, the diminution in speed of absorption of the first two hydrogens to reduce the aldehyde group was much less than the diminution in speed of absorption of the succeeding two to three molecular equivalents of hydrogen. The larger amount of ferrous chloride, at the same time as it acts as a protection for the platinum catalyst from de-oxygenation, poisons the catalyst more readily in its activity toward the reduction of the ethylene double bonds than it does toward the reduction of the aldehyde group.

From these results it may be concluded that in the reduction of furfural, as soon as a sufficient amount of ferrous chloride has been added to activate the platinum catalyst, no more is necessary and this catalyst then remains exceedingly active in the reduction experiments, only an occasional reactivation with air or oxygen being necessary in order to reduce run after run of furfural without changing the catalyst. No attempt was made to find out how many portions of furfural could be reduced with the same catalyst under the conditions mentioned before the catalyst might become appreciably affected.

Many of the experiments in this investigation were carried out with platinum catalyst prepared from spectroscopically pure chloroplatinic acid. For the average laboratory, it would be a tedious matter to bring all the platinum to this state of purity before using it. Experiments were, therefore, conducted to determine whether similar results to those described above could not be obtained by using platinum oxide from the c. p. chloro-

platinic acid of commerce. Such platinum oxide, without the addition of ferrous chloride, proved to be a more effective catalyst in the reduction of furfural than the oxide from spectroscopically pure chloroplatinic acid but the activity did not approach that obtained when a little ferrous chloride was present. The difference in the activity of the oxide from the two grades of chloroplatinic acid may be attributed to the presence of traces of iron or other effective impurities in the c. p. chloroplatinic acid of commerce. The results of several experiments show that by the addition of the proper amount of ferrous chloride to the platinum oxide from c. p. chloroplatinic acid of commerce, results could be obtained almost identical with those described by the use of platinum oxide from purest raw material.

It was pointed out in previous papers that the catalyst from the c. p. chloroplatinic acid of commerce, after it had been reworked 19 several times, gradually accumulated sufficient impurities so that it became quite active as a catalyst in the reduction of aldehydes without the necessity of adding ferrous chloride. Moreover, the effectiveness of such a catalyst obtained by frequent reworking remained constant after a maximum activity had been reached. Such a catalyst was used for the reduction of a large amount of furfural. Using 50 g. of furfural, 150 cc. of alcohol and 1 g. of such platinum oxide, it was possible to complete the reduction (3.3 to 3.6 molecular equivalents) within a reasonable time with about six reactivations of the catalyst with air with each 50 g. of furfural. As many as six successive runs of 50 g. each of furfural were made with the same catalyst and only a slight diminution in the speed of reduction was noted. The speed of this reduction was less than half that which was obtained by the use of platinum oxide with the addition of the proper amount of ferrous chloride. Although no similar experiments were carried out with this catalyst in which oxygen was used for reactivation, it is probable that the time of reduction could be cut in half by such a procedure, as indicated by the results discussed in the following paragraph.

The importance and usefulness of reactivating the platinum catalyst during reduction experiments have been emphasized by a number of investigators, as well as in the previous papers on the use of platinum oxide as a catalyst. The procedure, as usually carrried out, is merely to shake the catalyst with air for a few minutes. The advantage of using oxygen in place of air for the reactivation has not been sufficiently emphasized. Standard experiments with exactly the same quantities of reagents were carried out, the only difference being in the mode of reactivation of the catalyst. By the use of oxygen, the time for reduction was much less than when air was used.

¹⁸ The term "reworked" has been applied to that platinum oxide which was made from chloroplatinic acid formed after a number of cycles as follows: chloroplatinic acid to platinum black→use of the platinum black as a catalyst→solution of the platinum black to give chloroplatinic acid.

From the variety of reduction experiments which have been completed, the best results were obtained as follows. A mixture of 50 g. of furfural in 150 cc. of alcohol, 1 g. of catalyst (either from c. p. or sp. p. chloroplatinic acid) and 1.2 cc. of 0.1 M ferrous chloride was treated with hydrogen under 1 to 2 atmospheres' pressure (Table I). One molecular equivalent of hydrogen was absorbed in about an hour, and the reduction ran to completion with the absorption of about 3.3 to 4.3 molecular equivalents of hydrogen in about 4 hours. During the reduction the catalyst was thrice reactivated with oxygen. When the reduction was complete the solution was decanted from the platinum, the catalyst reactivated with oxygen and then 50 g. of furfural in 150 cc. of alcohol was added. The reduction proceeded in practically the same time as for the first 50 g. A third run was carried out in a similar manner and gave the same results without showing any appreciable devitalization of the catalyst. Unquestionably, still additional portions of 50 g. of furfural could have been reduced with the same catalyst without appreciable diminution in the speed of reduction.

Furfural is a different type of aldehyde than those studied in a previous paper by Carothers and Adams, in that it contains additional reducible groups. In the reduction of furfural a difference in the speed of absorption of the first molecular equivalent of hydrogen to convert the aldehyde group to the alcohol was observed as compared with the reduction of the ethylene double bonds in the furane ring. This was particularly noticeable in those experiments where the reduction was not too rapid, illustrated especially well in the series of runs where reworked platinum catalyst was used without the addition of ferrous chloride and where air was employed for reactivating the catalyst. The first portion of hydrogen was invariably absorbed rapidly, but usually one whole molecular equivalent was not absorbed before reactivation of the catalyst was desirable. It was especially noticeable that the last fraction of the first molecular equivalent of hydrogen was slowly absorbed, and that as soon as one molecular equivalent was completely absorbed a second reactivation was desirable. As soon as the absorption of the second molecular equivalent of hydrogen had started with the reactivated catalyst, the reduction proceeded again very rapidly. The significant point in these experiments is that just as long as any aldehyde is present the platinum catalyst is rapidly rendered inactive, but just as soon as all the aldehyde is reduced, the platinum catalyst is not devitalized and the reduction continues to proceed rapidly. It frequently happened in these experiments that after all but 5 to 10% of the first molecular equivalent of hydrogen had been absorbed, the last 5 to 10% could not be absorbed even over a long period of time, unless the catalyst was reactivated. After reactivation the absorption of this last small amount did proceed fairly rapidly, but during the process, devitalized the catalyst considerably so that reduction, after the first molecular equivalent of hydrogen had been absorbed, went more slowly than it should. When, however, the catalyst was always reactivated just after the complete absorption of the first molecular equivalent of hydrogen, regardless of when the previous reactivation had been made, the reduction of the ethylene linkages in the furane ring went very rapidly.

In all of the experiments described above no attempt was made to control the temperature. It was noted, however, that whenever the hydrogen was absorbed rapidly, there was a marked increase in the temperature of the reaction mixture. If the reduction slowed down appreciably, the reaction mixture might cool off but become warm again as soon as the platinum catalyst was reactivated. In the experiments in which the oxygen was used for reactivation and the maximum activity was obtained by using ferrous chloride, the reaction mixture remained at a temperature of  $50\text{--}60^{\circ}$  during the whole period of reduction, merely due to the heat of reaction.

A few experiments were carried out in order to determine whether furfural might be reduced without using a solvent, or using only a small amount of solvent. It was found that furfural alone with the catalyst was not reduced. Neither was it reduced in the presence of water sufficient in amount not to cause the formation of two layers. On the other hand, satisfactory results were obtained by dissolving the furfural in twice its volume of 50% alcohol. Since the preliminary experiments showed that the furfural in three volumes of 95% alcohol reduced very satisfactorily, this proportion was arbitrarily adopted.

In previous papers it has been mentioned that the brown platinum oxide could either be added to the reaction mixture and the reduction started, or the platinum oxide could first be added to the solvent, reduced to platinum black and then the reagents added and the reduction started. In all of the work with furfural the platinum oxide was reduced first to platinum black before the other reagents were added.

The reduction of furfural derivatives was carried out with platinum oxide obtained from chloroplatinic acid which had been reworked several times. The reactivation of the catalyst was carried out with air. All of the experiments were made before the study of furfural itself was completed, so that perhaps the best conditions were not used in every case. Nevertheless, the reductions took place in most cases with surprising ease. Apparently, the devitalizing of the catalyst which occurred in the reduction of furfural did not occur in the reduction of the majority of derivatives. Although the speed of reduction for each of these substances is given in the Experimental Part, it is not particularly significant, since the probability is that by varying the conditions somewhat according to those used for furfural, it could be increased markedly.

Pyromucic acid was reduced with the formation of tetrahydro-pyromucic acid as a chief product. Lower- and higher-boiling fractions were formed,

however, the contents of which have not yet been determined. From analogy to the reduction of furfural it might be concluded that these fractions contain valerianic acid,  $\alpha$ -hydroxy- and  $\delta$ -hydroxy-valerianic acids.

The reduction of ethyl pyromucate took place only very slowly with the formation of a satisfactory yield of ethyl tetrahydro-pyromucate. It was obvious that very little decomposition of the ring took place as compared with the reduction of pyromucic acid.

The reduction of  $\beta$ -furyl-acrylic acid proceeded very rapidly with the absorption of three molecular equivalents of hydrogen to form  $\beta$ -tetrahydrofuryl-propionic acid. The by-product obtained in this reaction was small in amount, indicating the probable opening of the ring to only a very slight extent.

The reduction of furoin resembled closely the reduction of furfural owing, perhaps, to its similarity to furyl alcohol, the primary product in the reduction of furfural. By the absorption of 5 molecular equivalents, two glycols were obtained which, by analysis, proved to be stereo-isomeric dihydroxy-1,2-di-(tetrahydrofuryl)-1,2-ethanes. Besides these, some oily material resulted which was probably a complex mixture of polyhydroxy compounds such as might be formed by the rupture of one or both of the furane rings. The reduction was undoubtedly not complete when the hydrogenation was stopped.

The reduction of fural-acetone and fural-acetophenone took place with exceptional smoothness. A total of 4 molecular equivalents of hydrogen were absorbed before the reduction stopped; the first three were taken up very rapidly, reducing the aliphatic double bond and the two double bonds in the furane ring in each of the substances. The fourth molecular equivalent of hydrogen was absorbed comparatively slowly. When the reaction mixture was worked up after the first 3 molecular equivalents were absorbed, practically quantitative yields of pure ketone were obtained. When, however, 4 molecular equivalents were absorbed, the corresponding alcohol was obtained in quantitative yields. It has already been mentioned by previous investigators that fural-acetophenone could be reduced by hydrogen and platinum only to the saturated ketone. This is obviously incorrect.

## Experimental Part

Materials.—The furfural used in this work was kindly donated by the Miner Laboratories of Chicago, Illinois. The authors wish to express their appreciation of this gift. The commercial material was purified merely by distillation under diminished pressure. It was then placed in brown bottles and kept until needed for use.

The pyromucic acid was prepared by the method of Frankland and Aston,  20   $\beta$ -furyl-acrylic acid by the method of Gibson and Kahnweiler,  21  furoin by the method of

The spectroscopically pure chloroplatinic acid was made from ordinary c. p. chloroplatinic acid 25  of commerce by the method of E. Wichers. 26 

Reduction Experiments.—The apparatus used in the reduction was that described previously in this series of papers.³

The platinum oxide catalyst was made from chloroplatinic acid by the method described in the last paper. In all the experiments the platinum oxide was reduced to platinum black before the substance to be reduced was added. The procedure followed in each case was to add the platinum oxide to the reaction flask and wash it in carefully with a little water. There was then added sufficient alcohol to make the liquid about a 50% alcohol and then it was shaken with hydrogen under pressure until the platinum oxide turned black. This required from half a minute to a maximum of two or three minutes, providing the platinum oxide had originally been prepared in the proper way. The 50% alcohol which was present was allowed to remain in the bottle when the solution of alcohol for reduction was added.

The reductions were all carried out with hydrogen under a pressure of 1 to 2 atmospheres.

The reactivations of the catalyst were all carried out in a similar way. The bottle was evacuated, air or oxygen was passed in and the reaction mixture shaken for 10 minutes. The bottle was then again evacuated and filled with hydrogen before the reduction was continued. The first reactivation of the catalyst was invariably carried out an hour after the start of the reduction. Subsequent reactivations were made hourly in those experiments where the reductions proceeded rapidly, or every two or more hours in those experiments where the reductions were slow.

The procedure for working up the reaction mixture was very simple. As soon as the reduction was complete the bottle was allowed to stand for perhaps 30 minutes until the platinum settled. The solution was decanted or filtered, the alcohol distilled and the resulting residue fractionated under ordinary or diminished pressure.

**Explanation of Table.**—The total molecular equivalents of hydrogen which had been absorbed after definite periods of time are given in one column. The readings that were actually taken represented fall in pressure which was then converted to molecular equivalents of hydrogen. Since

²⁵ The C. P. chloroplatinic acid in this investigation was the C. P. grade purchased from the Mallinckrodt Chemical Company. It contained traces of iron and other impurities.

²⁶ Wichers, This Journal, 43, 1268 (1921).

the drop in pressure varied between different limits, the molecular equivalents are approximate but are all within the general experimental error.

The asterisk (*) represents reactivation with oxygen, as described above. The reactivations were made at the ends of the time periods represented by the numbers directly before the signs, and also at beginning of each successive run (B, D, E) of a series.

Ten complete tables of exact experimental results which have led to the conclusions discussed in the introductory part of this paper could not be published on account of the necessity of conserving space in This Journal. If desired, copies of these tables may be procured by writing to the author (Adams).

TABLE I
BEST CONDITIONS FOR RAPID REDUCTION OF FURPILIFAL

Columns A and B represent reduction with the same 1 g. of catalyst (c. p.), each run containing 50 g. of furfural in 150 cc. of alcohol (95%). Expts. C, D and E present a series of runs with the same 0.5 g. of catalyst (sp. p.) each run using 25 g. of furfural, in 75 cc. of alcohol (95%). To Run A only was added 1.2 cc. of 0.1 M ferrous chloride.

Isolation of Products from Furfural Reduction.—The best results were obtained by distilling the crude material obtained from the reduction of six 50g. runs under ordinary pressure until all of the material boiling below 180° had passed over. This removed all the low-boiling products and most of the tetrahydrofuryl alcohol. The remainder was distilled under diminished pressure, and fractions were collected as follows: to 80°/3 mm., 80–95°/3 mm., 95–105°/3 mm., 105–118°/3 mm., 118–123°/3 mm. Three refractionations were then carried out under diminished pressure until most of the material had separated into fractions boiling up to 80°/3 mm., 95–105°/3 mm., and 118–123°/3 mm. These three fractions were then distilled under ordinary pressure and pure materials obtained as described below.

n-Amyl Alcohol (V).—From each 600 g. of furfural only a very small amount of the fraction boiling at 130–145° was obtained. By careful fractionation, 5 g. was isolated which boiled at 137–139° (751 mm.);  $n_1^{15}$ , 1.4114;  $d_2^{20}$ , 0.8266. It had the characteristic odor of amyl alcohol and gave the proper constants and analytical results.

Analyses. Subs., 0.2757:  $CO_2$ , 0.6872;  $H_2O$ , 0.3282. Calc. for  $C_6H_{12}O$ : C, 68.18; H, 13.63. Found: C, 67.98; H, 13.32.

Undoubtedly the amount of this product formed was considerably greater than that actually isolated in a pure state.

Tetrahydrofuryl Alcohol (II).—From the material boiling at 145-180° a large frac-

tion boiling at 174–180° was obtained which proved to be identical with the tetrahydro-furyl alcohol made and described in the literature. When pure it boiled at 177–178° (743 mm.);  $n_{\rm p}^{19}$ , 1.4502;  $d_{\rm 20}^{20}$ , 1.0514.

Pentanediol-1,2 (III).—The fraction boiling at 95–105° (3 mm.) upon fractionation under ordinary pressure gave a large proportion boiling at 210.5–211.5° (751 mm.) or 99–100° (3 mm.);  $n_{\rm p}^{19}$ , 1.4412;  $d_{\rm p}^{20}$ , 0.9802.

Analyses. Subs., 0.8086: CO₂, 0.6493;  $H_2O$ , 0.3155. Calc. for  $C_5H_{12}O_2$ : C, 57.69; H, 11.53. Found: C, 57.38; H, 11.44.

This product was further identified as a glycol by conversion into the diacetate.

Pentanediol-1,2-diacetate.—The glycol was refluxed with a large excess of acetic anhydride for 3 hours. The reaction product was then fractionated under diminished pressure and yielded a practically quantitative amount of a diacetate boiling at  $219-220^{\circ}$  (748 mm.) or  $103-104^{\circ}$  (2 mm.);  $n_{\rm p}^{20}$ , 1.4202;  $d_{\rm 20}^{20}$ , 1.0148.

Analyses. Subs., 0.3962:  $CO_2$ , 0.8341;  $H_2O$ , 0.2988. Calc. for  $C_9H_{16}O_4$ : C, 57.44; H, 8.51. Found: C, 57.42; H, 8.44.

Pentanediol-1,5; (Pentamethylene Glycol) (IV).—The high-boiling fraction of the original reaction mixture gave, upon distillation, constant-boiling fractions at 237–239° (751 mm.) or 119–120° (3 mm.);  $n_D^{20}$ , 1.4499;  $d_D^{20}$ , 0.9939. It was a practically water-clear liquid, miscible with water, alcohol and ether. Its constants agree with those of pentamethylene glycol prepared in a different manner. It gives a diacetate the constants of which agree with those previously found for this compound.

Analyses. Subs., 0.2349: CO₂, 0.4968;  $H_2O$ , 0.2383. Calc. for  $C_5H_{12}O_2$ : C, 57.69; H, 11.53. Found: C, 57.68; H, 11.36.

Pentanediol-1,5-diacetate.—This was prepared in exactly the same manner as the pentanediol-1,2-diacetate. It was a colorless liquid boiling at  $241.5-243.5^{\circ}$  (748 mm.) or  $122-123^{\circ}$  (3 mm.);  $n_D^{19}$ , 1.4261;  $d_D^{20}$ , 1.0296.

Analyses. Subs., 0.2765: CO₂, 0.5799; H₂O, 0.2099. Calc. for  $C_9H_{16}O_4$ : C, 57.44; H, 8.51. Found: C, 57.20; H, 8.50.

Furyl Alcohol (I).—From 200 g. of furfural reduced in 50 g. portions merely until one molecular equivalent of hydrogen had been absorbed, using the same 1 g. of catalyst, there was obtained 180 g. of practically pure furyl alcohol boiling at 168–170° (754 mm.);  $n_2^{20}$ , 1.4828;  $d_2^{20}$ , 1.1357.

#### Reduction of Furfural Derivatives

Catalyst (c. P.) was used in all the experiments on furfural derivatives and reactivations with air were employed. The experiments were completed before the distinct advantage of using oxygen for reactivation was found.

Pyromucic Acid to Tetrahydro-pyromucic Acid.—A sample of 25 g. of pyromucic acid in 100 cc. of alcohol (95%) was reduced with 0.5 g. of catalyst in about 4 hours. By fractionation of the reaction product tetrahydro-pyromucic acid was obtained to the extent of about 40% of the total reaction mixture. In addition, there were low- and high-boiling products present which are now being studied. Wienhaus and Sorge¹⁴ did not in their work mention that any products besides tetrahydro-pyromucic acid were obtained. When pure, tetrahydro-pyromucic acid was water-clear and boiled at  $131-132^{\circ}$  (14 mm.); m. p.,  $21^{\circ}$ ;  $n_{19}^{19}$ , 1.4585;  $d_{20}^{20}$ , 1.1933.

Ethyl Pyromucate to Ethyl Tetrahydro-pyromucate.—The reduction of ethyl pyromucate took place much more slowly than the reduction of pyromucic acid. For the reduction of 25 g. of ethyl pyromucate in 75 cc. of 95% alcohol in the presence of 0.5 g. of catalyst, 45 hours was necessary with frequent reactivation of the catalyst with air. About 20 g. of crude reduction product was obtained from the reaction mixture and

of this 13 g. boiled at a constant temperature of 82° (11 mm.);  $n_{\rm p}^{18}$ , 1.4455;  $d_{20}^{20}$ , 1.0792. It had a pleasant, fruity odor, and was insoluble in water but soluble in alcohol and ether.

Analyses. Subs., 0.4049: CO₂, 0.8620; H₂O, 0.3105. Cale. for C₇H₁₂O₃: C, 58.29; H, 8.39. Found: C, 58.06; H, 8.56.

β-Furyl-acrylic Acid to β-Tetrahydrofuryl-propionic Acid,  $C_4H_7O$ — $CH_2CH_2$ - $CO_2H$ .—The reduction of 25 g. of β-furyl-acrylic acid in 75 cc. of 95% alcohol in the presence of 0.5 g. of catalyst was complete in about 2 hours. After fractionation 10 g. of pure β-tetrahydrofuryl-propionic acid was obtained boiling at 135–137° (4 mm.);  $n_p^{19}$ , 1.4562;  $d_{20}^{20}$ , 1.1155. It was obviously identical with the substance prepared by Windaus¹6 and Dalmer. In addition to this main product was low- and high-boiling material which has not yet been identified.

Furoin to Dihydroxy-1,2-di-(tetrahydrofuryl)-1,2-ethane,  $C_4H_7O$ —CHOHCH-OH— $C_4H_7O$ .—A solution of 20 g. of pure furoin in 200 cc. of 95% alcohol was reduced with 1 g. of catalyst. The initial temperature in this experiment was about 35°, since furoin is not very soluble in cold alcohol, and even at the temperature mentioned a certain amount remained undissolved. The reduction proceeded rapidly and at the end of 6 hours, the catalyst having been reactivated with air only once, five molecular equivalents of hydrogen had been taken up. Apparently, further reduction was taking place but it was stopped at this point. Two such runs as these were made and the reaction products mixed before being worked up.

After filtering the platinum and evaporating the alcohol, a liquid was obtained from which a few crystals deposited on standing. The whole mixture, without removal of these crystals, was distilled under diminished pressure, when the major portion boiled from 145-200° (2 mm.). This distillate was a yellowish oil from which crystals deposited on standing. The crystals were filtered out and recrystallized from a very small amount of 95% alcohol. About 4 g. of the recrystallized product was thus obtained (Product A). The alcoholic filtrate from the recrystallization was added to the oil from which the crude crystals had been filtered and the alcohol removed from the mixture. There resulted 34 g. of yellow oil which on standing became semisolid. This was again fractionated under diminished pressure and two portions were collected, one boiling at 140-170° at 2 mm. and the other at 170-205° at 2 mm. The higher of these two fractions gradually solidified in the receiver. It weighed about 5 g. and contained a large percentage of Product A.

The fraction boiling from 140–170° (2 mm.) and weighing 26 g. was again fractionated and a constant-boiling fraction distilling at 147–148° (2 mm.) obtained. This solidified immediately to a pure white substance which melted at 75° (Product B). About 12 g. of this solid was obtained. No convenient method for recrystallizing it was found.

PRODUCT A.—Product A is a white crystalline solid, readily soluble in water and alcohol but only slightly soluble in ether, benzene or ethyl acetate. It can readily be crystallized from alcohol after which it melts at 167°.

Analyses. Subs., 0.2687:  $CO_2$ , 0.5843;  $H_2O$ , 0.2100. Calc. for  $C_{10}H_{18}O_4$ : C, 59.36; H, 8.98. Found: C, 59.30; H, 8.75.

PRODUCT B.—Product B is a white solid readily soluble in alcohol and water. It is more soluble in benzene, ether or ethyl acetate than Product A. It boils at 147–148° (2 mm.) after which it solidifies and melts at 75°.

Analyses. Subs., 0.2782: CO₂, 0.5982;  $H_2O$ , 0.2188. Calc. for  $C_{10}H_{18}O_4$ : C, 59.36; H, 8.98. Found: C, 58.64; H, 8.80.

Fural-acetone to Tetrahydrofuryl-1-butanone-3 and to Tetrahydrofuryl-1-butanol-3.—A solution of 55 g. of pure fural-acetone in 150 cc. of 95% alcohol was reduced in the presence of 1 g. of catalyst. The first molecular equivalent of hydrogen was ab-

sorbed in 20 minutes. The catalyst was reactivated and the second molecular equivalent of hydrogen was absorbed in 30 minutes. Again the catalyst was reactivated and the third molecular equivalent of hydrogen was absorbed in 70 minutes. The reduction in a number of experiments was stopped at this point. In other experiments the catalyst was again reactivated and the absorption carried on until a fourth molecular equivalent of hydrogen had been taken up. The absorption of this last molecular equivalent generally required between 8 and 15 hours with several reactivations of the catalyst. When the reduction was stopped after the absorption of 3 molecular equivalents, practically a quantitative yield of the ketone was obtained, and when four molecular equivalents were absorbed practically a quantitative yield of the alcohol was obtained.

Tetrahydrofuryl-1-butanone-3,  $C_4H_7O$ — $CH_2CH_2COCH_3$ —In the reduction of 55 g. of fural-acetone it was not difficult to obtain 40 g. of completely purified tetrahydrofuryl-1-butanone-3. The ketone was a water-clear liquid of pleasant odor, which gradually became yellowish on standing. It was insoluble in water but readily soluble in alcohol and ether. It boiled at 81° (2 mm.);  $n_p^{19}$ , 1.4459;  $d_{20}^{20}$ , 0.9815.

Analyses. Subs., 0.2055:  $CO_2$ , 0.5065;  $H_2O$ , 0.1763. Calc. for  $C_8H_{14}O_2$ : C, 67.55; H, 9.93. Found: C, 67.22; H, 9.60.

Tetrahydrofuryl-1-butanol-3,  $C_4H_7O$ — $CH_2CH_2CHOHCH_3$ .—From 55 g. of fural-acetone 42 g. of absolutely pure alcohol could readily be obtained. It was a colorless, odorless liquid which did not become colored on exposure to air. It was practically insoluble in water but soluble in alcohol and ether. It boiled at 93–94° (2 mm.);  $n_D^{19}$ , 1.4546;  $d_{20}^{20}$ , 0.9774.

Analyses. Subs., 0.2182:  $CO_2$ , 0.5343;  $H_2O$ , 0.2244. Calc. for  $C_6H_8O_2$ : C, 66.61; H, 11.19. Found: C, 66.78; H, 11.51.

Fural-acetophenone to Tetrahydrofuryl-1-phenyl-3-propanone-3 and Tetrahydrofuryl-1-phenyl-3-propanol-3.—The reduction took place rapidly as in the case of the fural-acetone. It was possible to reduce 25 g. of pure fural-acetophenone in 75 cc. of alcohol with 0.5 g. of catalyst until three molecular equivalents of hydrogen had been absorbed in about 2 hours, with only one reactivation of the catalyst. The absorption of the fourth molecular equivalent of hydrogen required about 8 hours and two reactivations of the catalyst. The yields of ketone after three molecular equivalents of hydrogen had been absorbed, and of alcohol after four equivalents had been absorbed, were practically quantitative.

Tetrahydrofuryl-1-phenyl-3-propanone-3,  $C_4H_7O$ — $CH_2CH_2COC_6H_5$ .—From 25 g. of fural-acetophenone 18 g. of perfectly purified ketone was obtained boiling at 153–154° (2 mm.);  $n_D^{20}$ , 1.4885;  $d_{20}^{20}$  1.0913. It was a practically colorless liquid, insoluble in water but soluble in alcohol and ether.

Analyses. Subs., 0.3050: CO₂, 0.8577; H₂O, 0.2056. Calc. for C₁₃H₁₆O₂; C, 76.42; H, 7.90. Found: C, 76.69; H, 7.54.

Tetrahydrofuryl-1-phenyl-3-propanol-3,  $C_4H_7O$ — $CH_2CH_2CHOHC_6H_6$ .—From 25 g. of fural-acetophenone about 21 g. of absolutely purified alcohol was obtained boiling at 167–168° at 2 mm.;  $n_2^{20}$ , 1.5245;  $d_{20}^{20}$ , 1.0601. It was a water-clear liquid, insoluble in water but soluble in alcohol and ether.

Analyses. Subs., 0.2697:  $CO_2$ , 0.7490;  $H_2O$ , 0.2145. Calc. for  $C_{12}H_{18}O_2$ : C, 75.67; H, 8.80. Found: C, 75.74; H, 8.90.

#### Summary

1. The reduction of furfural in alcohol solution, using platinum oxide as a catalyst, has been studied. By the absorption of one molecular equivalent

of hydrogen, furyl alcohol is obtained in quantitative yields. When the reduction is carried further, 2.3 to 3.3 additional molecular equivalents of hydrogen are absorbed with the formation of a mixture of four products; tetrahydrofuryl alcohol, pentanediol-1,2, pentanediol-1,5 and *n*-amyl alcohol. The first of these is formed in largest amounts and the amounts of the others decrease in the order given.

- 2. It has been found that platinum oxide from spectroscopically pure chloroplatinic acid or c. p. chloroplatinic acid of commerce is a very ineffective catalyst toward the reduction. In the presence of small amounts of ferrous chloride, however, the reduction takes place very rapidly. A series of experiments using increasing amounts of ferrous chloride showed an increase in the speed of reduction up to a certain maximum beyond which larger amounts caused a diminution in speed. The larger amounts of ferrous chloride have a greater poisoning effect on the platinum as a catalyst toward the reduction of the ethylene linkages in the furane ring than toward the reduction of the aldehyde group.
- 3. The amount of ferrous chloride which afforded a maximum activity for a certain weight of platinum catalyst produced the same activity when double the amount of platinum and double the amount of reagents were used.
- 4. Platinum catalyst that has been redissolved and reprecipitated as oxide a number of times accumulates a certain amount of impurity so that it is active for the reduction of furfural without the addition of ferrous chloride. The activity of such catalyst, however, is much less than the activity in the presence of a little ferrous chloride.
- 5. The distinct advantage of using oxygen in place of air for reactivation of the catalyst has been demonstrated.
- 6. The best method for reducing furfural found in this research was by the use of 50 g. of furfural, 150 cc. of alcohol, 1 g. of catalyst and 1.2 cc. of 0.1 M ferrous chloride. Using hydrogen under 1 to 2 atmospheres' pressure the absorption of about 4 molecular equivalents of hydrogen took place in 4 hours. Three reactivations of the catalyst were made with oxygen during this period. This is in contrast to the reduction of furfural described by a previous investigator where 48 g. of furfural was used and 285 hours and 10 additions of fresh catalyst were required for the reduction.
- 7. By the use of the platinum oxide catalyst, furfural derivatives were readily reduced; pyromucic acid was converted to tetrahydro-pyromucic acid; ethyl pyromucate to ethyl tetrahydro-pyromucate;  $\beta$ -furyl-acrylic acid to  $\beta$ -tetrahydrofuryl-propionic acid; furoin to two stereo-isomeric dihydroxy-1,2-di-(tetrahydrofuryl)-1,2-ethanes; fural-acetone to tetrahydrofuryl-1-butanone-3 and to tetrahydrofuryl-1-butanol-3; fural-acetophenone to tetrahydrofuryl-1-phenyl-3-propanone-3 and tetrahydrofuryl-1-phenyl-3-propanol-3.

# THE ACTION OF SULFUR UPON PARA-TOLUIDINE IN THE PRESENCE OF LITHARGE. THIO-PARA-TOLUIDINE, ITS CONSTITUTION AND SOME NEW DERIVATIVES

By Marston Taylor Bogert and Malvin R. Mandelbaum Received August 21, 1923

#### Introductory

When p-toluidine and sulfur are heated together, various products are formed depending upon the proportions of initial materials, temperature and duration of the heating, presence or absence of such hydrogen sulfide absorbents as litharge, and other factors. The commercially important products are dehydrothio-p-toluidine and primuline, but one of the simplest is the "thio-p-toluidine" first isolated by Merz and Weith from a melt obtained by heating p-toluidine with sulfur at  $140^{\circ}$  in the presence of litharge.

The literature concerning the structure of this latter compound is inconclusive and contradictory. Merz and Weith merely gave the molecular formula as C₁₄H₁₆N₂S. In fact, they even failed to state until 15 years later^{2,3} which toluidine they used. Truhlar⁴ investigated the compound quite extensively, at the request of Professor Merz, and prepared a large number of derivatives, but did not commit himself further regarding the constitution of the base than to write the formula as (CH₃.C₆H₃.NH₂)₂S and to propose the name "amidothio-p-tolyl." Dahl and Co.3,5 patented certain of the azo dyes obtainable from this amine, characterizing the base as "thio-p-toluidine (of melting point 103°)." Green, however, adopted Formula II, but without citing any experimental proof in support thereof, and expressed the opinion that it was the antecedent substance from which both dehydrothio-p-toluidine and primuline were formed by further action of sulfur, since he had actually obtained7,8 primuline from it in this way. Subsequently he changed his views regarding the origin of the dehydrothio-p-toluidine and suggested a different explanation. In 1890, Purgotti¹⁰ removed the amino groups through the diazo reaction and stated that he obtained a di-o-tolyl sulfide, from which he concluded that the Merz

and Weith base should be represented by Formula III. Beilstein¹¹ gives the preference to Formula II.

Hence, it seemed to us worth while to study this problem somewhat more fully, so as to establish definitely the constitution of the Merz and Weith base and to determine under what conditions, if any, it could be converted into dehydrothio-p-toluidine. As set forth in what follows, we believe that we have solved the first of these two problems, but the work upon the second is unfinished and the report thereon must be deferred to a later communication.

The plan of attack involved the preparation of the base by the Merz and Weith method, examination of the product and comparison of the same with ditolyl sulfides synthesized in other ways.

In the repetition of the process of Merz and Weith, it was found far more satisfactory to isolate the products from the crude melt by a method which rested upon the assumption of a sufficient difference in basicity to permit their successive extraction from a benzene solution by a series of acids each stronger than its predecessor. In this way, p-toluidine, thio-p-toluidine and dithio-p-toluidine were isolated.

Purgotti¹⁰ prepared di-o-tolyl sulfide (o-cresyl sulfide) from o-toluidine by the customary diazo-reaction, and described his product as an oil, boiling at 285°. Since the product he obtained by de-amination of the Merz and Weith base was similar in appearance and boiled at 284–286°, the two were regarded as identical, although he gave no analytical data or other criteria of purity or of identity. Both Zeiser¹² and Mauthner, ¹³ however, have since shown that pure di-o-tolyl sulfide is a solid, which melts at 64° and boils at 174° at 15 mm. pressure. Purgotti's product, therefore, must have been either very impure or something else. Mauthner prepared also the di-m-tolyl sulfide as a colorless oil, boiling at 174° at 12 mm. pressure, and the o-tolyl-m-tolyl sulfide as a colorless and odorless oil, boiling at 170° at 11 mm. pressure. There is thus but little difference in the boiling points of the three isomers and, as a means of identifying such isomers, it is consequently of little value.

On repeating Purgotti's experiment for the elimination of the amino groups from the Merz and Weith base, much difficulty was encountered in our efforts to get a product of unquestionable purity. Our lack of success here corresponded with that of Truhlar, who found it impossible to replace the amino groups by halogen or cyanogen through the diazo reaction, although he did succeed in getting the phenol finally.

The sulfide obtained from the Merz and Weith base by de-amination

¹¹ Beilstein, "Handbuch der Organischen Chemie," Leopold Voss, 3d ed., 1903, II, 821, and Suppl., II, 483.

¹² Zeiser, Ber., 28, 1674 (1895).

¹³ Mauthner, Ber., 39, 3595 (1906).

therefore was easily oxidized to the sulfone, forming colorless crystals melting sharply at 94°, and whose analysis gave figures agreeing closely with those calculated for a ditolyl sulfone. Di-o-tolyl sulfone has been reported¹⁰ as melting at 134–135°, and the di-p-tolyl isomer¹⁴₁⁵ at 158°, but we failed to find in the literature any record of the di-m-tolyl sulfone. It is obvious, however, that Purgotti was in error in concluding that the sulfide obtained by de-aminating the Merz and Weith base was the di-o-tolyl compound, as he would have discovered very quickly himself had he carried his work one step farther and oxidized it to the sulfone.

It remained, then, to check the accuracy of the deduction that our sulfone melting at 94°, and its antecedent sulfide, were actually the *meta* compounds, and this was accomplished by synthesizing di-m-tolyl sulfide from m-iodotoluene and sodium m-thiocresylate. In this undertaking, it was found advantageous to prepare the necessary m-thiocresol from benzaldehyde-m-sulfo acid, rather than by the methods hitherto recorded in the literature. When this synthetic di-m-tolyl sulfide was oxidized, it yielded a sulfone identical in appearance with that obtained from the deaminated Merz and Weith base and which also melted sharply at 94°. An intimate mixture of the two melted at the same point.

Further, among the by-products of the thio-p-toluidine melt, there was found a yellowish-brown, waxy solid, which formed a beautifully crystalline acetyl derivative, melting at 213° (corr.). The analysis of this acetyl derivative showed that it contained carbon and hydrogen in the proportion present in a bis(acetaminotolyl) disulfide, (CH₃CONH(CH₃)C₆H₃)₂S₂. Jacobson and Ney¹⁶ have described the diacetyl derivative of bis(2-amino-5-methylphenyl) disulfide (V) as crystallizing in similar form and as melting at 204–206°.

These facts seem to us to justify the conclusion that thio-p-toluidine should be represented by Formula II, and not by III. Of course, this does not exclude the possibility of III, or even IV, being formed also in the thio-p-toluidine melt, but we have uncovered no proof of their presence or of dehydrothio-p-toluidine. Nor have we encountered either p-amino dithiobenzoic acid,  $H_2NC_6H_4CSSH$ , or its p-toluidide, which Green suggested as intermediate products in the conversion of p-toluidine into dehydrothio-p-toluidine. It is quite likely, on the other hand, that small amounts of stilbene derivatives are formed in this reaction, since Aronstein and van Nierop¹⁷ found that on long (120 hours) boiling of toluene with sulfur, hydrogen sulfide was liberated and some stilbene produced,

and our own experiments have demonstrated the fact that sulfur acts much more vigorously upon toluene in the presence of litharge, or other hydrogen sulfide absorbents, likewise with formation of stilbene.

Our experiments then indicate that when p-toluidine is heated with sulfur, in the presence of litharge and at a temperature of 140-145°, the main course of the reaction is the formation first of the mercaptan (I). This, then, through the simultaneous oxidizing influence of sulfur and litharge. unites with unchanged p-toluidine to thio-p-toluidine (II), while small amounts (generally not over 5%) escape this reaction and are oxidized directly to the disulfide (V). In the absence of litharge, and at the higher temperatures employed (180-220°) for the manufacture of dehydrothiop-toluidine and primuline, the mercaptan condenses with the methyl group of unchanged p-toluidine, instead of with its nuclear hydrogen, thus generating a compound which is more stable than thio-p-toluidine under these conditions of temperature. This deduction as to the course of the reaction by which dehydrothio-p-toluidine (VI) is formed from p-toluidine and sulfur, is in accord with the surmise of Friedlaender. 18 Conversely, Gattermann and Pfitzinger¹⁹ have shown that when dehydrothio-ptoluidine is fused with potassium hydroxide, it is hydrolyzed to the mercaptan (I) and p-aminobenzoic acid. Schultz and Beyschlag20 treated m-tolylene diamine with sulfur in boiling alcohol solution and obtained a bis(2,4-diamino-5-methylphenyl) polysulfide, proving that here also the sulfur entered meta to the methyl group and ortho to the amino.

We have tried in vain to convert thio-p-toluidine into dehydrothio-p-toluidine by the action of heat alone, and also in the presence of sulfur or of p-toluidine. These experiments are being continued since, as already mentioned, Green obtained primuline from thio-p-toluidine and sulfur. The explanation of this apparent discrepancy may lie in the fact that "primuline" is really the name not of a chemical individual but of a group of compounds of high molecular weight, produced from p-toluidine and sulfur at elevated temperatures, through elimination of varying amounts of hydrogen sulfide. The manner in which the p-toluidine residues combine, and the number of residues so uniting, differ considerably, but all have certain tinctorial properties in common. The constitution of most of them is still unknown.

Through its diacetyl derivative, thio-p-toluidine was oxidized to bis(2-acetamino-5-carboxyphenyl) sulfone, which was then de-acetylated (VII) and the product esterified. It is hoped that some of the esters so accessible may exhibit the local anesthetic properties characteristic of p-aminobenzoic esters (benzocaine, propaesin, cycloform, etc.), for the physio-

²⁰ Schultz and Beyschlag, Ber., 42, 743 (1909).

logical effects of the sulfonals appear to depend mainly upon the alkyl groups present and not upon the sulfone bridges.

The disulfide (V) corresponding to thio-p-toluidine was discovered by Jacobson and Ney. It is a homolog of the bis(2-aminophenyl) disulfide originally described by Hofmann and recently put upon the market as a remedy for syphilis under the name of "Intramin." The isomeric disulfides from 2-amino-4-methylphenyl mercaptan and 4-amino-2-methylphenyl mercaptan are also known. It is a matter of some historical interest that the diacetyl derivative of dithio-p-toluidine (V) agrees closely in crystalline form, solubilities and melting point, with what Truhlar thought was the diacetyl derivative of thio-p-toluidine itself. Our experiments have shown that when crude thio-p-toluidine, containing even very small amounts of the disulfide, is acetylated, it is the diacetyl derivative of the disulfide which separates immediately and not that of thio-p-toluidine. This would account for Truhlar's error, except for the fact that his analytical figures check for the mono- and not for the disulfide derivative.

**Experimental Part** 

Fusion of p-Toluidine and Sulfur, and Treatment of the Crude Melt.—The claim of the Dahl patent³ that a yield of thio-p-toluidine amounting to about 60% of that

²¹ Hofmann, Ber., 12, 2363 (1879).

²² Ber., 42, 4310 (1909).

²³ Ber., 45, 1496, 1501 (1912).

calculated can be obtained by the Merz and Weith process is not in agreement with our experience, for our yields of pure product (m. p., 103-104° corr.) were invariably far below that figure. We found it advisable, therefore, to modify the method somewhat, as explained in what follows.

A mixture of  $1070 \, \mathrm{g}$ . of p-toluidine (10 moles) and 320 g. of sulfur (10 equivalents) was melted in a suitable flask, and the temperature of the melt raised gradually to  $140-145^{\circ}$ , where it was maintained while litharge was added slowly in small amounts and with vigorous stirring, until further addition no longer caused effervescence or rise of temperature. Usually, this condition was attained after some  $1600 \, \mathrm{g}$ . of litharge had been added during  $6 \, \mathrm{hours}$ .

In most cases, the reaction proceeded quite smoothly with evolution of steam, but occasionally the flask boiled over without apparent cause. This was due neither to the rate of addition of the litharge, nor to any detectable impurity in the latter.

The presence of iron or nickel wool (sometimes partially oxidized), or substitution of other oxides or carbonates for the litharge, with the object of providing an absorbent for hydrogen sulfide which would not react as rapidly with free sulfur, failed to improve the yield of final product. With ferric or zinc oxide, no reaction occurred even at 165°. With lead carbonate, a reaction took place at 165–170°, but the higher temperature necessary offset any advantage which might have been inherent in this substitution.

It seemed not unlikely that the thio-p-toluidine as formed was attacked by the unchanged sulfur present and that the velocity of this decomposition was determined by the concentrations of thio-p-toluidine and of sulfur, and the temperature and duration of the heating. Under the conditions noted above, equilibrium appeared to have been reached when the amount of thio-p-toluidine present was such as to give a final yield of approximately 30% of that calculated from the p-toluidine actually consumed in the operation. In support of this assumption, it was found that an increase in the amount of sulfur used in the reaction resulted in no increase in the yield of thio-p-toluidine, but a decrease in the weight of p-toluidine recovered and the formation of more tarry by-products. Similarly, any considerable prolongation of the heating after the requisite amount of litharge had been added tended to diminish the yield.

Upon completion of the reaction, the melt was agitated with 3 to 4 liters of boiling 95% alcohol, some "Sil-o-Cel" added, and the mixture filtered hot, giving a dark brown filtrate. Addition of an alcoholic solution of oxalic acid to this filtrate precipitated the p-toluidine quantitatively as oxalate, free from sulfur compounds, and proved a rapid and convenient way of following the progress of the reaction in the smaller scale preliminary experiments. It was not the best way, however, of recovering the p-toluidine in the major runs, when it was desired to isolate also the other products of the reaction. The usual method of procedure was to distil the alcohol from this filtrate, take up the residue in benzene and extract the benzene solution with acids of increasing strength. Benzene was not used for the preliminary extraction of the melt, since it rendered the filtration from the lead sulfide sludge much more tedious and troublesome. The residue obtained by evaporating the alcohol from the filtrate mentioned, amounting to about 1080 g. generally (equivalent to 88% of the combined weight of initial p-toluidine plus half the sulfur), was poured into 1500 cc. of benzene.

Extraction of the benzene solution with aqueous solutions of different acids was carried out in a tall cylinder equipped with a mechanical stirrer and siphon, for this was found to be more satisfactory than the use of a large separatory funnel.

An unstable salt with one of the products of its hydrolysis constantly withdrawn into another phase should be almost completely hydrolyzed, while a more stable one, under identical conditions would remain but little affected. Hence, in the case of two immiscible solvents, such as benzene and water, in one of which the free base is the more soluble, and in the other the salt, it should be possible to extract a benzene solution of

free bases with aqueous solutions of suitable acids, thus forming a series of salts of which only those of the stronger bases would be stable in the presence of the other phase and remain in the aqueous extract. Thus, by selection of the proper acids, of gradually increasing ionization constants, the attempt was made to extract the various bases seriatim. In the absence of exact quantitative data concerning the strength of the bases to be extracted, it was assumed that the order of basicity was probably p-toluidine > thio-p-toluidine > dithio-p-toluidine. The acids chosen were acetic (k = 0.000018), citric (k = 0.00081), tartaric (k = 0.00109), oxalic (k = 0.10), and sulfuric. These values for k are all at the uniform temperature of 25°. Dilute (15%) acetic acid failed to extract all of the p-toluidine. Dilute (15%) citric acid extracted practically all of the p-toluidine, with only traces of thio-p-toluidine. Tartaric acid likewise extracted the p-toluidine, but formed with it a more difficultly soluble salt and so was less satisfactory.

Successive extractions of the benzene solution were conducted, therefore, with 1 liter portions of dilute (15-20%) citric acid, and the temperature was kept at  $25^{\circ}$  to avoid separation of p-toluidine citrate, which is rather difficultly soluble at lower temperatures. The separated extracts were neutralized with ammonia, and p-toluidine was precipitated in small colorless crystals. Those obtained from the first extraction often showed a reddish tinge, due to traces of an impurity which possessed the properties of an indicator, giving a yellow solution with acids and a red one with bases. When further extraction with citric acid yielded on neutralization only a slight turbidity, the remaining citric acid was removed from the benzene layer by washing it once with water. Five or six extractions in this way with citric acid yielded 320 g. of pure p-toluidine.

The benzene layer was extracted next with a saturated aqueous solution of oxalic acid, also used in 1-liter portions. The yellow extracts were united and diluted with at least an equal volume of water, to provide for the rather low solubility of ammonium oxalate, and then neutralized with ammonia. The crude thio-p-toluidine thus precipitated was light yellow and fairly pure (m. p., about  $100^{\circ}$ ), except that separated from the final extraction, which was apt to be colored a darker yellow from contamination by small amounts of the disulfide. Four or five extractions yielded 276 g. of crude thio-p-toluidine, equivalent to 32% of that calculated after allowing for the p-toluidine recovered. Since p-toluidine oxalate is but slightly soluble in water or the more common organic solvents, it was very easy to determine whether any p-toluidine had escaped the citric acid extraction.

During the final oxalic acid extractions, a heavy viscous tar separated in the extraction cylinder, thus giving a 3-phase system, composed of an upper benzene layer, an intermediate aqueous oxalic acid layer, and a lower one of tar. After siphoning off the oxalic layer, the benzene layer and tar were washed with water, the water was separated and the benzene layer decanted from the tar.

Extraction of the benzene layer was then resumed, using dilute (10%) sulfuric acid. Neutralization of the sulfuric acid extracts gave 40 g. of a yellow, waxy solid, which proved to be the crude disulfide (V). The yield of this never exceeded 5% of the weight of the p-toluidine entering into reaction. Some tar separated also in these extractions.

The extracted benzene solution was finally evaporated and the dark viscous residue boiled with concd. hydrochloric acid and filtered. When this hydrochloric acid extract was poured into water, a small amount of yellow solid precipitated, but it was not dehydrothio-p-toluidine (VI), for its alcoholic solution exhibited no fluorescence.

The tar separated during the oxalic acid extractions was digested with fresh benzene, in the presence of a 5% sodium hydroxide solution, to recover any organic bases present. The benzene layer was separated and the solvent driven off. There remained 35 g. of a heavy, greenish oil. The tar separating from the sulfuric acid extractions was treated similarly, and yielded 70 g. of a dark bluish oil. Neither acetyl nor benzoyl derivatives could be prepared from either of these oils. Addition of phenyl isocyanate to their

benzene solutions precipitated amorphous solids, insoluble in the usual organic solvents, with the exception of nitrobenzene, from which they deposited in a greenish, pulverulent form.

Thio-p-toluidine (II).—The crude thio-p-toluidine, obtained as described above, was dissolved in hot dil. (10%) hydrochloric acid, and to this hot solution coned. hydrochloric acid was added until precipitation began. As the solution cooled, pale yellowish needles of the hydrochloride separated. These were dissolved in hot water, the solution was heated with animal charcoal, filtered, and ammonia added in excess to the filtrate. Thio-p-toluidine separated as a pale yellow powder, melting at 102–103°, sufficiently pure for most purposes. The yield was 80% of the crude substance. A single crystallization from dil. alcohol gave a pure product in lustrous, colorless scales; m. p., 103–104° (corr.). This melting point was not altered by further crystallization and agrees with that reported by other investigators.

The picrate, benzoyl derivative (m. p., 186°), and urethan (m. p., 113°), were also prepared and agreed entirely with Truhlar's description of them.

Diacetyl Derivative.—This was obtained by the action of acetic anhydride, or of acetyl chloride, upon the base. It crystallized from alcohol in large rhombic plates; m. p., 165° (corr.).

Analyses. Calc. for  $C_{18}H_{20}O_2N_2S$ : C, 65.85; H, 6.10; S, 9.76. Found: C, 65.76, 65.85; H, 5.91, 5.78; S, 9.46.

As noted in the introductory portion of this paper, this product is not the same as the one (m. p., 211°) which Truhlar believed to be the diacetyl derivative of thio-p-toluidine, nor have we been able to obtain his product from pure thio-p-toluidine, although many different methods of acetylation were applied.

Di-m-tolyl Sulfide.—Forty-one g. of thio-p-toluidin was dissolved in 200 cc. of alcohol, 28 cc. of coned. sulfuric acid added, and the mixture warmed until a clear solution resulted. This solution was stirred vigorously during preliminary cooling, so that whatever sulfate separated would be in a finely divided state. The mixture was then further cooled to 0-5°, and maintained at that temperature, with constant stirring, while a solution of 27.2 g. of sodium nitrite in 45 cc. of water was run in slowly. After all the nitrite had been added, the dark red solution was left at 0° for 3 hours. Four g. of copper powder was then added. A slow evolution of gas commenced immediately and the temperature of the solution gradually rose. After standing overnight at laboratory temperature, the solution was boiled for 2 hours under a reflux condenser and then distilled at 100°, to remove aldehyde, alcohol and water. The tarry residue was extracted with chloroform, the extracts dried over calcium chloride and fractionated under diminished pressure. Six and a half g. of a pale amber, highly refracting oil was thus secured, boiling at 197° (23 mm.), 200° (25 mm.), and 202° (28 mm.). Purgotti¹⁰ reported the boiling point of the ditolyl sulfide obtained by him from thio-p-toluidine (by the action of nitrous acid and alcohol) as 284-286° at atmospheric pressure, but gave no further information concerning his process or product, other than the bald statement that its analysis (not given) and other properties (not specified) proved it to be the di-o-tolyl sulfide (o-cresyl sulfide), identical with that prepared by him from o-toluidine.

In order to secure a di-m-tolyl sulfide of high purity, benzaldehyde-m-sulfo acid was converted into the benzalchloride-m-sulfochloride, which was reduced to m-thiocresol, and the sodium salt of the latter then condensed with m-iodotoluene in the presence of copper powder. This process starts with readily accessible materials, is neither difficult nor laborious, and gives an excellent yield of water-clear thiocresol.

Of the methods utilized by other investigators, toluene-m-sulfochloride²⁴ is not so easily obtainable, while the employment of m-toluidine as initial material is expensive

²⁴ Huebner and Post, Ann., 169, 51 (1873).

and involves some risk of explosion in the conversion of the diazonium salt to the thiocresol through the xanthogenate. ²⁵

Benzaldehyde-m-sulfo acid was made from benzaldehyde and fuming sulfuric acid, by the method of Wallach and Wuesten. Fifty-five g. of the aldehyde yielded 85 g. of the sodium m-sulfonate. From the dry salt and phosphorus pentachloride the crude benzalchloride-m-sulfochloride was obtained. This was reduced directly by zinc dust and dil. sulfuric acid at 0°, giving the m-thiocresol as a colorless, highly-refracting liquid, of extremely disagreeable odor; b. p., 195°; yield, 18 g. from 75 g. of the sodium m-sulfonate, or 40%.

One g. of metallic sodium was dissolved in 18 cc. of absolute alcohol, 5.7 g. of m-thiocresol added and the alcohol distilled. To the residual, colorless solid were added 0.2 g. of copper powder and 10.6 g. of m-iodo-toluene, and the whole was heated for several hours at 235-240°. When cold, the mixture was treated with alcohol, the alcoholic solution acidified with sulfuric acid, some zinc dust added, and steam blown through as long as it carried over any oily distillate. The residual sludge was extracted with ether, the ethereal solution dried over calcium chloride and distilled. Three g. of di-m-tolyl sulfide was thus obtained as a pale yellowish, highly-refracting oil; b. p., about 290°. This is essentially the method of Mauthner. 13

Di-m-tolyl Sulfone.—The di-m-tolyl sulfide thus synthesized was suspended in boiling 40% acetic acid and oxidized carefully by gradual addition of 5 g. of powdered potassium permanganate. The sulfone as formed collected with the manganese oxide sludge, from which it was extracted by alcohol. On crystallization from the same solvent, it was obtained in colorless needles; m. p., 94°. Five g. of the sulfide yielded 3 g. of the sulfone.

Similar treatment of the ditolyl sulfide resulting from the de-amination of thio-p-toluidine gave a sulfone of the same appearance and melting point. An intimate mixture of the two also melted sharply at 94°. This sulfone from the thio-p-toluidine was analyzed.

Analyses. Calc. for  $C_{14}H_{14}O_2S$ : C, 68.29; H, 5.69. Found: C, 68.27, 68.19; H, 5.69, 5.51.

Bis(2-aceto-amino-5-methylphenyl) Sulfone,  $(CH_3CONH(CH_3)C_6H_3)_2SO_2$ .—Fortyfour g. of thio-p-toluidine was acetylated with 45 cc. of acetic anhydride, and the reaction product poured into a solution of 300 cc. of glacial acetic acid in 400 cc. of water. The resulting solution was heated to boiling, and 48 g. of potassium permanganate dissolved in 250 cc. of hot water was added gradually in small amounts. The oxidation ensued rapidly and the solution was filtered hot from precipitated manganese oxides. Some of the sulfone crystallized from the filtrate as it cooled, and more was recovered therefrom by partially neutralizing the solution with ammonium hydroxide. From the precipitated manganese oxides also some was collected by extraction with alcohol. The total amount obtained was 35 g. It crystallized from alcohol in long prismatic needles; m. p.,  $225^{\circ}$  (corr.).

Analyses. Calc. for C₁₈H₂₀O₄N₂S: C, 60.00; H, 5.55. Found: C, 60.37; H, 5.66. Three g. of this sulfone was heated for several hours at 180° with 15 cc. of concd. sulfuric acid, and then for 30 minutes longer at 300°. The cooled solution was poured upon twice its volume of ice. A small amount of tar separated and was removed. By further dilution of the filtrate, 2 g. of yellow solid was precipitated, which proved to be the de-acetylated sulfone (m. p., 206°) described beyond. No toluidine sulfo acids were found among the products.

Bis(2-amino-5-methylphenyl) Sulfone.—The diacetyl derivative was hydrolyzed by boiling it with dil. (15%) sulfuric acid until a clear solution resulted. This warm solution was poured with stirring into an excess of ammonium hydroxide solution. The amino sulfone separated as a yellow powder, and was crystallized from alcohol, when it appeared in yellow granular crystals, melting at 210° (corr.), practically insoluble in water or in dilute acids; yield, 6 g. from 8.5 g. of the diacetyl derivative.

Analyses. Calc. for C₁₄H₁₆O₂N₂S: C, 60.87; H, 5.80. Found: C, 61.17, 60.77; H, 6.32, 5.99.

Bis(2-aceto-amino-5-carboxyphenyl) Sulfone.—Ten and eight-tenths g. of finely pulverized diacetyl-thio-p-toluidine (m. p., 165°) was added to a solution containing 32 g. of potassium permanganate and 24 g. of magnesium sulfate in 750 cc. of water. The mixture was boiled under a reflux condenser until the color of the permanganate was discharged, when it was filtered hot and the hot filtrate acidified with sulfuric acid. Eight g. of the dicarboxylic acid separated as a fine, white precipitate, insoluble in the common neutral organic solvents. It was purified by washing it with hot alcohol and then with ether, and showed a melting point (with decomposition) above 360°.

Analyses. Calc. for C18H16O8N2S: C, 51.43; H, 3.86. Found: C, 50.56, 52.48; H, 3.83, 4.07.

Bis(2-amino-5-carboxyphenyl) Sulfone (VII).—The free amino acid was prepared from its diacetyl derivative by boiling the latter with dil. (10%) sodium hydroxide solution and precipitating the filtrate with dil. hydrochloric acid. It was difficultly soluble in the ordinary organic solvents and likewise melted above 360° with decomposition.

Methyl Ester .- As obtained from the acid, methyl alcohol and hydrogen chloride, it crystallized from alcohol in thin, square, colorless tablets with ridged diagonals; m. p., 234° (corr.).

Analyses. Calc. for C₁₆H₁₆O₆N₂S: C, 52.70; H, 4.40. Found: C, 52.85, 52.94; H, 4.49, 4.67.

Ethyl Ester.—This was obtained as yellowish, transparent prisms (from alcohol): m. p., 206° (corr.).

Analyses. Calc. for C₁₈H₂₀O₆N₂S: C, 55.10; H, 5.10. Found: C, 55.14; H, 5.09.

Structurally, these esters are composed of two benzocaine (anesthesine) molecules united by a sulfone (sulfuryl) bridge, and hence might be expected to exhibit some local anesthetic action. Unfortunately, the solubility of the methyl and ethyl esters was too low to cause any pronounced physiological effects, as indicated by preliminary tests. but the field is being explored further, in the hope of discovering more soluble derivatives of therapeutic value.

Bis(2-nitro-4-methylphenyl) Sulfide (VIII).-Forty g. of crystallized sodium sulfide, Na₂S.9H₂O, and 88 g. of 4-iodo-3-nitrotoluene were dissolved in 300 cc. of alcohol. and the dark brown solution boiled for 12 hours under a reflux condenser. The alcohol was distilled and the residue poured into water. On standing overnight, 27 g. of a dark red oil collected. This was washed repeatedly with dilute acid and with alkali. After several days, it solidified partially, yielding 4 g. of crystals. Re-crystallized from acetone, it appeared in large, dark red, short prisms, giving a yellow powder when crushed; m. p., 125-126° (corr.).

Analyses. Calc. for C₁₄H₁₂O₄N₂S: C, 55.26; H, 3.95. Found: C, 55.21, 55.36; H. 3.85, 3.40.

Bis(2-aceto-amino-5-methylphenyl) Disulfide.—Ten g. of the crude dithio-ptoluidine obtained from the sulfuric acid extraction of the p-toluidine sulfur melt as already described, was treated with 12 cc. of acetic anhydride. Rapid solution occurred, with evolution of considerable heat, and the entire mass soon congealed to a brown crystalline magma. This was washed with water, and then crystallized repeatedly from alcohol, giving bunches of small, snow-white, silky needles; m. p., 213° (corr.). At higher temperatures, it sublimed with decomposition.

Analyses. Calc. for  $C_{18}H_{20}O_2N_2S_2$ : C, 60.00; H, 5.55. Found: C, 60.12, 60.28; H, 5.54, 5.80.

This compound agrees in appearance, solubility and percentage composition, with the acetyl derivative obtained by Jacobson and Ney¹⁶ from the corresponding amine, except that they gave the melting point as 204–206°.

Bis(2-amino-5-methylphenyl) Disulfide (Dithio-p-toluidine) (V).—The diacetyl derivative was hydrolyzed by boiling it with concd. hydrochloric acid, the amine hydrochloride precipitating. It was dissolved in water, the base liberated by the addition of excess of ammonium hydroxide and purified by crystallization from dil. alcohol. Long, greenish needles were obtained; m. p., 88.5° (corr.). Jacobson and Ney gave its melting point as 89°.

Truhlar states that when he treated his thio-p-toluidine with a slight excess of acetic anhydride, crystals of the acetyl derivative soon appeared which when washed with water and crystallized from alcohol separated quickly and copiously in bundles of snow-white silky needles, melting at 211°.

Judging from the resemblance in melting point and other properties that what Truhlar believed to be the diacetyl derivative of thio-p-toluidine was actually the disulfide derivative, we prepared some crude thio-p-toluidine by the Merz and Weith process and subjected it to acetylation as described by Truhlar. The crystals which separated first were removed and recrystallized from alcohol, yielding small, snow-white, silky needles, melting at 213°, identical with the disulfide derivative just mentioned, and giving the disulfide (m. p., 88.5°) on hydrolysis. This same crude thio-p-toluidine, after being freed from all disulfide, yielded only the diacetyl derivative (m. p., 165°) of thio-p-toluidine recorded above.

## Summary

- 1. The structure of the thio-p-toluidine of Merz and Weith is proved to be bis(2-amino-5-methylphenyl) sulfide.
- 2. The course of the action of sulfur upon p-toluidine, in the presence of litharge and at 140–145°, is shown to lead first to the formation of 4-amino-3-mercapto-toluene, part of which oxidizes to the disulfide, while the major portion reacts with more p-toluidine, yielding thio-p-toluidine.
- 3. The acetyl derivative described by Truhlar as a thio-p-toluidine compound is probably the disulfide derivative.
- 4. Certain derivatives of di-m-tolyl sulfide are recorded, as well as a new synthesis of m-thiocresol.
- 5. New derivatives of thio-p-toluidine also have been prepared and studied.

THE ACTION OF ALKALI ON SUBSTITUTED URIC ACIDS. I
1,3-DIMETHYL-9-PHENYL-URIC ACID

By Elizabeth Stuart Gatewood¹ Received August 23, 1923

All of the substituted uric acids are split by alkali to some extent, the amount of decomposition depending largely on the number and position of the substituents. With one exception, that of tetramethyluric acid, neither the nature of the decomposition products nor the mechanism of the reaction has been investigated up to this time. A thorough study of the action of alkali on substituted uric acids is now being made.

Of these, 1,3-dimethyl-9-phenyl-uric acid shows a smooth and interesting decomposition. The course of the decomposition and the structure of the products are considered to be as follows.

Dimethyl-phenyl-uric acid is very slowly decomposed by  $4\ N$  alkali at room temperature; the sodium salt separates on the addition of the base, and only a small part is attacked after standing for many days. At  $100^\circ$  with more dilute alkali the decomposition is more rapid, and with  $4\ N$  alkali it is instantaneous. The gas given off is methylamine and when the solution is acidified carbon dioxide is evolved. From the acid solution on standing a crystalline product separates which melts at  $250^\circ$ . Analysis shows that it has the formula  $C_{11}H_{11}O_3N_3$ .

There are three possible structures for this substance, depending on which of the methylamino groups and which of the carbonyls are lost.

¹ National Research Fellow in Chemistry.

² Fischer, Ber., 30, 3012 (1897).

When warmed with alkali or even on standing about an hour with cold alkali, the product is completely decomposed to phenylurea, methylamine, oxalic acid and formic acid. The phenylurea separates after standing only 15 minutes but no oxalic acid can be detected at this point unless the solution is first warmed, showing that the formation of oxalic acid is due to a secondary reaction. Most probably, glyoxalic acid is first formed, and this is converted into oxalic acid and glycolic acid when warmed or allowed to stand for a long time with alkali.

On the basis of this decomposition, Structure III for  $C_{11}H_{11}O_3N_3$  must be excluded, as there is no possibility of the formation by hydrolysis of either oxalic or formic acid. Carbon dioxide and glycolic acid would be the products formed. Either of the other two structures can give these products of hydrolysis, however.

(I) 
$$CH_3NH-CO$$

$$C-NH$$

$$HOC-NC_6H_5$$
(II)  $HOOC$

To decide between these structures, the substance was oxidized by hydrogen peroxide in dilute alkaline solution. A product melting at  $194-195^{\circ}$  was isolated. Its empirical formula was found to be  $C_{11}H_{11}O_4N_3$ . The most probable structural formula for this substance is IV, and such a substance can result from the alkaline decomposition product only if it has Structure I.

Furthermore, the oxidation product is itself instantly decomposed by cold alkali, and the products of decomposition are phenylurea and the methylamide of mesoxalic acid.³ On boiling with alkali the decomposition goes further. Methylamine is evolved, phenylurea separates from the alkaline solution, and mesoxalic acid can be isolated in the form of its phenylhydrazone.

One of the most interesting things about this decomposition is that the *Torrey, Ber., 31, 2162 (1898).

oxidation product is of the same type of compounds as those Biltz⁴ has obtained in his caffolide decompositions. It bears a close relationship to alloxanic acid⁵ and other similar hydantoin derivatives, for it is the methylamide of 3-phenyl-5-hydroxyhydantoin-5-carboxylic acid. This type of substance Biltz obtained from caffolide or substituted caffolides by boiling with water, and he found that they were all easily decomposed by alkali to give an amine, a urea and mesoxalic acid, just as is the oxidation product of  $C_{11}H_{11}O_3N_3$ . On reduction they gave hydantoin-carboxylic acid derivatives of Type V which differs from the structure assigned to the alkaline decomposition product,  $C_{11}H_{11}O_3N_3$ , only in having a —HC— group

instead of a—C— group.  $C_{11}H_{11}O_3N_3$  cannot, however, be such a hydantoin HOC—

derivative; it is not decomposed by alkali to a hydantoin or a hydantoin-carboxylic acid as the amides of the hydantoin-carboxylic acids have been found to be. There was the possibility that phenylhydantoin had been formed and further decomposed by alkali to phenylurea. When 3-phenylhydantoin was prepared, however, and treated with alkali, it gave only phenylhydantoic acid. The alkaline decomposition product must, therefore, be an isohydantoin derivative, namely 3-phenyl-isohydantoin-5-carboxylic acid methylamide.

The experimental part of this paper gives an account of 1,7-dimethyl-9-phenyl-uric acid which has been synthesized for the first time. Like 9-phenyl-uric acid and 7-methyl-9-phenyl-uric acid,7 it is quite stable toward alkali when boiled for a short time.

This new uric acid is 1,7-dimethyl-9-phenyl-uric acid and not 3,7-dimethyl-9-phenyl-uric acid for, as Biltz⁸ has proved, when there is only one substituting group in the pyrimidine ring, the ring closing of the pseudouric acids always takes place so that this group is in Position 1 of the uric acid. A further proof that the methyl occupies Position 1 is that methylation of 7-methyl-9-phenyl-uric acid with dimethyl sulfate gives, along with some trimethyl phenyl uric acid, the same dimethyl phenyl uric acid as obtained above, and it is well known that dimethyl sulfate always methylates first on the nitrogen whose hydrogen is least acidic.⁹

The investigation of the action of alkali on tetramethyluric acid and on

1,3,7-trimethyl-9-phenyl-uric acid is already well advanced, and work on 1,3,9-trimethyl-uric acid will be begun shortly.

In conclusion, the writer wishes to express her appreciation to Professor F. J. Moore, of the Massachusetts Institute of Technology, for his valuable advice during the course of this investigation.

## Experimental Part

### 1,3-Dimethyl-9-phenyl-uric Acid

Action of Alkali.—1,3-Dimethyl-9-phenyl-uric acid¹⁰ was prepared from the corresponding pseudo-uric acid, which was obtained by the action of phenyl isocyanate on 1,3-dimethyl-uramil.

One hundred cc. of  $4\ N$  sodium hydroxide solution was added to  $2\ g$ . of finely powdered dimethyl-phenyl-uric acid. The solution was heated gradually to boiling and boiled about half a minute, cooled slightly, and then acidified with dil. hydrochloric acid. After the solution had stood for several hours (sometimes longer), a crystalline substance started to separate. It was left overnight, and when filtered and dried gave from  $1.2\ to$   $1.4\ g$ . of phenylisohydantoin-carboxylic acid methylamide, in a yield of about 80%. It crystallized from hot water in bunches of needles which melted at  $249-250\ c$  to a clear, viscous, yellow liquid. It was recrystallized again and dried in a vacuum over sulfuric acid for analysis.

Analyses. Subs., 0.1541, 0.1511: CO₂, 0.3174, 0.3100; H₂O, 0.0677, 0.0653. Subs., 0.1411, 0.0965: N, 22.9 cc.  $(23.5^{\circ}, 759.1 \text{ mm.})$ , 15.8 cc.  $(23^{\circ}, 759.1 \text{ mm.})$ . Calc. for  $C_{11}H_{11}O_3N_3$ : C, 56.62; H, 4.76; N, 18.03. Found: C, 56.22, 56.28; H, 4.92, 4.76; N, 18.14, 18.34.

OPTICAL PROPERTIES.—Habit, rectangular plates; extinction, parallel,  $\alpha$  parallel to clongation; interference figure, biaxial, large optic angle; indices,  $\alpha = 1.571$ ,  $\gamma = 1.620$ .

The other products of decomposition, methylamine and carbon dioxide, were determined—the first as methylamine chloroplatinate and the second by absorption in soda lime.

On the addition of chloroplatinic acid to the hydrochloric acid solution of the gas evolved from the alkaline-solution, orange crystals were obtained melting at 230–233°; mixed with a known sample of methylamine chloroplatinate they melted at 233°. The optical properties were also the same: habit, thin hexagonal plates; optical orientation, isotropic; index of refraction, 1.74.

One molecular equivalent of carbon dioxide was given off when the alkaline solution was acidified.

Analysis. Subs., 2.00: CO2, 0.391 g. Calc. for 1 mol.: 0.32 g.

Dimethyl-phenyl-uric acid is only very slowly attacked by cold 4 N alkali. The sodium salt of the uric acid separates and after 20 days at room temperature most of the acid is regained when the solution is acidified. From the filtrate, on standing, a small amount of phenylisohydantoin-carboxylic acid methylamide, melting at  $240^{\circ}$ , was obtained.

The sodium salt of dimethyl-phenyl-uric acid was dried at 100-110° and analyzed. Analysis. Subs., 0.2092: NaSO₄, 0.0500. Calc. for C₁₃H₁₁O₃N₄Na: Na, 7.823. Found: 7.905.

Phenylisohydantoin-carboxylic acid methylamide when refluxed for  $1^{1}/2$  hours with acetic anhydride gave, after evaporation of the mixture to dryness and addition of

¹⁰ Ref. 7, p. 143.

ether, a product melting at 185–187°. There was not sufficient material for analysis.

The alkaline decomposition product did not react with phenylisocyanate either when heated to 165°, or in alkaline solution at 0°, showing it to be an acid amide.

Action of Alkali on Phenylisohydantoin-carboxylic Acid Methylamide.—I. One g. of the alkaline decomposition product was heated with 4 cc. of 4 N alkali and the gas given off absorbed in a little dil. hydrochloric acid. This solution gave, on the addition of chloroplatinic acid and subsequent evaporation, the characteristic orange crystals of methylamine chloroplatinate, melting at 228–230°.

Phenylurea separated from the alkaline mother solution as it cooled. It melted at 144°; mixed with a pure sample of phenylurea, it melted at 146°. The optical properties were the same: habit, plates; extinction, parallel,  $\gamma$  parallel to elongation; interference figure, biaxial, large optic angle; birefringence, weak; indices,  $\alpha=1.602$ ,  $\gamma=1.627$ . To identify the substance further as phenylurea, it was boiled with aniline, and diphenylurea was obtained in good yield. It melted at 236–238°; a mixture with a pure sample of diphenylurea, melted at 237–238°. The optical properties were identical: habit, long needles; extinction, parallel,  $\gamma$  parallel to elongation; interference figure, biaxial; birefringence, strong; indices,  $\alpha=1.620$ ,  $\gamma$ , indeterminate.

When the filtrate was acidified with acetic acid and a solution of calcium chloride added, a fine, white precipitate of calcium oxalate was obtained.

2. When  $0.1~\rm g$ . of the decomposition product was allowed to stand at room temperature with 1 cc. of 4 N sodium hydroxide, crystals of phenylurea began to separate after 15 minutes and the odor of methylamine could be detected. After half an hour the solution was filtered. The yield of phenylurea was  $0.015~\rm g$ .; m. p.,  $145^{\circ}$ . Half of the filtrate was acidified with acetic acid and a solution of calcium chloride added. The solution remained clear, showing that no oxalic acid was present. The other half was first warmed and then tested for oxalic acid as before. A precipitate of calcium oxalate separated at once.

- 3. When 0.1 g. was left at room temperature with 1 cc. of 4 N sodium hydroxide for over 1 hour, 0.02 + g. of phenylurea was obtained, and the filtrate gave calcium oxalate but the precipitate was not as heavy as in 1.
- 4. When 0.1 g. was dissolved in 8.2 cc. of water and 0.4 g. of potassium hydroxide and evaporated to dryness at  $30-40^{\circ}$ , the residue gave, after the addition of water, 0.02 g. of phenylurea (52%) and 0.035 g. of calcium oxalate (63%).
- 5. Formic acid was identified as one of the products of decomposition by its reduction of an ammoniacal solution of silver nitrate. Phenylisohydantoin-carboxylic acid methylamide was boiled with  $4\,N$  sodium hydroxide, the solution acidified with sulfuric acid and distilled. The distillate was warmed with ammoniacal silver nitrate; metallic silver was precipitated. The distillate was also tested for formaldehyde but with negative results.

Oxidation of Phenylisohydantoin-carboxylic Acid Methylamide with Hydrogen Peroxide.—On oxidation of the alkaline decomposition product with peroxide in very dilute alkaline solution, phenylurea and oxalic acid are obtained when the oxidation solution is allowed to stand for 3 hours or longer at room temperature. The decomposition is doubtless due only to the alkali, for a solution of the same concentration but without the peroxide gave the same products.

When the oxidation is allowed to proceed for only 5 minutes at 0-10° and the solution then acidified and evaporated, an oxidation product, melting at 195-196°, can be isolated. It is the methylamide of 3-phenyl-5-hydroxyhydantoin-5-carboxylic acid.

1. To 0.5 g. of the decomposition product in 6 cc. of water, 1.5 g. of solid potassium hydroxide and 35 cc. of 3% hydrogen peroxide were added. The solution was cooled and after 3 hours acidified and evaporated. A 69% yield of phenylurea and a 50% yield of calcium oxalate resulted.

2. One g. of the alkaline decomposition product was added to 12 cc. of water and cooled to 5°; 2.9 g. of potassium hydroxide and 70 cc. of 3% hydrogen peroxide were then added, and the temperature kept below 10°. After 5 minutes the solution was acidified with dil. hydrochloric acid and evaporated in a vacuum. Large clumps of material usually separated, which weighed about 0.6 g. It was purified by recrystallization from hot water many times. A little boneblack was added the first time. The pure product consisted of glistening flakes; m. p., 194–195°. It was very soluble in hot water, alcohol, acetone, and ethyl acetate, and was insoluble in ether and chloroform. It was dried in a vacuum over sulfuric acid for analysis.

Analyses. Subs., 0.1397, 0.1440:  $CO_2$ , 0.2730, 0.2795;  $H_2O$ , 0.0572, 0.0531. Subs., 0.1994, 0.1478: N, 29.6 cc. (23°, 756.7 mm.), 21.9 cc. (25°, 760.0 mm.). Calc. for  $C_1H_{11}O_4N_3$ : C, 53.01; H, 4.45; N, 16.87. Found: C, 53.28, 52.93; H, 4.58, 4.13; N, 16.56, 16.44.

OPTICAL PROPERTIES.—Habit, large, thin, rect. plates; extinction, parallel,  $\alpha$  parallel to elongation; interference figure, biaxial, large optic angle; indices,  $\alpha = 1.545$ ,  $\gamma = 1.583$ .

On further evaporation the solution gave more of the oxidation product, mixed with another substance from which it could not be completely separated. A small amount of the latter was separated mechanically. It crystallized from water in fine needles, melting at 188–190°. It was soluble in alcohol, acetone and ethyl acetate, and insoluble in ether and chloroform. It was not decomposed by alkali.

OPTICAL PROPERTIES.—Habit, needles; extinction, parallel,  $\alpha$  parallel to elongation; birefringence, strong; indices,  $\alpha=1.556$ ,  $\gamma=1.695$ .

Action of Alkali on the Oxidation Product.—1. Seven cc. of 2 N sodium hydroxide was added to 0.2 g. of the oxidation product. It dissolved at once and in a few minutes crystals began to separate. Air was passed through the solution while it was carefully heated. The gas evolved was absorbed in dil. hydrochloric acid, chloroplatinic acid added, and the solution evaporated. Orange crystals separated which melted at 228–230°; when these were mixed with methylamine chloroplatinate the melting point was not lowered. Their optical properties were the same. Phenylurea was obtained from the alkaline solution on cooling. Its melting point, 145–146°, and optical properties agreed with those of a known sample. The filtrate gave no test for oxalic acid.

2. One cc. of 4 N sodium hydroxide was added to the oxidation product. The solution was warmed carefully until the crystalline precipitate that had formed dissolved. It was then cooled, 1 cc. of water added, and the phenylurea filtered off. The yield was 0.09 g. or 90%. The filtrate was carefully neutralized with dil. acetic acid and a solution of 0.06 g. of pure phenylhydrazine in 1 cc. of water and 4 drops of glacial acetic acid added. A yellow precipitate gradually formed. The solution was warmed until clear and when cool was acidified with dil. hydrochloric acid. A heavy, yellow precipitate separated which crystallized from dil. alcohol in small, hexagonal crystals; m. p., 167°. It was very similar to the phenylhydrazone of mesoxalic acid and was at first thought to be this substance. However, on preparing mesoxalic acid by the convenient method of Chattaway and Harris, 11 and from it the phenylhydrazone, it was found that they were not the same. Mesoxalic acid phenylhydrazone was more soluble in water and crystallized in fine needles melting at 165°; when mixed with the above product the mixture melted at 150°. The optical properties also were different.

OPTICAL PROPERTIES OF THE PHENYLHYDRAZONE OF MESOXALIC ACID.—Habit, fine needles; extinction, parallel,  $\alpha$  parallel to elongation; indices,  $\alpha = 1.450$ ,  $\gamma > 1.800$ .

OPTICAL PROPERTIES OF THE PHENYLHYDRAZONE MELTING AT  $167^{\circ}$ .—Habit, hexagonal plates; extinction, symmetrical,  $\alpha$  parallel to elongation; interference figure, biaxial, large optic angle; birefringence, strong; indices,  $\alpha = 1.600$ ,  $\gamma = 1.715$ .

¹¹ Chattaway and Harris, J. Chem. Soc., 121, 2704 (1922).

It was found to be the phenylhydrazone of the methylamide of mesoxalic acid, the same substance Torrey³ obtained by the mild action of barium hydroxide on allocaffuric acid. He gives the melting point as 158°. The difference may be accounted for, however, by the well-known variation of the melting points of phenylhydrazones with rate of heating. Its solution in concd. sulfuric acid developed a red-violet color on the addition of ferric chloride; it was almost insoluble in water and, when boiled for a short time with sodium hydroxide, gave a substance melting at 205–210° (Torrey gives 205–209°). According to Biltz¹² this is the phenylhydrazone of glyoxalic acid methylamide.

3. When the oxidation product was boiled for several minutes with alkali, a strong odor of methylamine developed, and from the solution, after separation of the phenylurea and neutralization, mesoxalic acid itself was isolated as its phenylhydrazone. It crystallized from water in fine, yellow needles, melting at 160°, and mixed with a known sample gave the same melting point. The optical properties also were identical.

At one time it was thought that the oxidation product of phenylisohydantoin-carboxylic acid methylamide had the composition  $C_{10}H_{11}O_2N_3$  and that it might be the methylamide of phenyloxaluric acid,  $CH_3NHCO$ —CONHCONHC $_6H_5$ . This substance was not known, but it can be easily synthesized. Oxamethane,  13   $C_2H_5OOC$ -CONH $_2$ , when heated with phenyl isocyanate, gives the ethyl ester of phenyloxaluric acid,  $C_2H_5$ -COOC-CONHCONHC $_6H_5$ , and this with methylamine gives the desired compound.

Preparation of the Ethyl Ester of Phenyloxaluric Acid.—Five g. of oxamethane, finely powdered, was added to 10 g. of phenyl isocyanate, and heated in an open tube at 110–112° for one hour. A clear solution resulted, which solidified as it cooled to a mass still having a strong odor of phenyl isocyanate. The solid was dissolved with hot absolute alcohol and the solution filtered. A well-crystallized product separated, which weighed 4.7 g. It was recrystallized from alcohol and melted at 125–126°, with evolution of gas.

Analyses. Subs., 0.1579, 0.1958: N, 17 cc.  $(24^{\circ}, 772.1 \text{ mm.})$ ; 20.8 cc.  $(20^{\circ}, 771.4 \text{ mm.})$ . Calc. for  $C_{11}H_{12}O_4N_2$ : N, 11.87. Found: 12.19, 12.28.

OPTICAL PROPERTIES.—There were two crystalline species. A. Extinction, parallel,  $\alpha$  parallel to elongation; interference figure, biaxial; indices,  $\alpha = 1.590$ ,  $\gamma = 1.680$ . B. Extinction angle, 17–19°; birefringence, weak; indices,  $\alpha = 1.675$ ,  $\gamma = 1.755$ .

Optical Properties of Oxamethane.—Habit, large, thin, rectangular plates; extinction, parallel,  $\alpha$  parallel to elongation; interference figure, biaxial; indices,  $\alpha = 1.545 + , \gamma = 1.620$ .

Preparation of the Methylamide of Phenyloxaluric Acid.—One g. of a 33% solution of methylamine was added dropwise to 1 g. of the ethyl ester suspended in 10 cc. of water. After the resulting product had stood for half an hour, it was filtered off and dried on a tile; m. p., 210–215°; yield, 0.74 g. Phenyloxaluric acid methylamide is difficultly soluble in hot water, alcohol, acetone and chloroform. No good solvent for it was found. Microscopical examination showed that the substance was mixed with phenylurea. They could be partially separated by boiling with alcohol. The residue melted over a range of more than 5°, showing it was still not pure and the analysis indicated the same.

Analyses. Subs., 0.1383, 0.1338: N, 20.4 cc. (21°, 756.8 mm.), 24.1 cc. (25°, 759.5 mm.). Calc. for  $C_{10}H_{11}O_{3}N_{3}$ : N, 18.99. Found: 19.56, 19.96.

Optical Properties.—Extinction, parallel,  $\alpha$  parallel to elongation; indices,  $\alpha=1.595, \gamma=1.700.$ 

¹² Ref. 4c, p. 1603.

¹³ Weddige, J. prakt. Chem., 10, 196 (1874).

Phenyloxaluric acid methylamide was instantly decomposed by cold 4 N alkali. A crystalline product separated, part of which melted at 140–145° and the rest about 210°. Under the microscope it was seen to be a mixture of phenylurea and diphenylurea (impurity in the original material). Oxalic acid was found in the filtrate. The gas given off by the alkaline solution was methylamine, as it gave a chloroplatinate melting at 228–230°.

## 1,7-Dimethyl-9-phenyl-uric Acid

The starting point in the synthesis of 1,7-dimethyl-9-phenyl-uric acid is 1,7-dimethyl-uramil. It was prepared by oxidizing theobromine with potassium chlorate, reducing the product to 7-methyl-dialuric acid, and treating this with methylamine.

Preparation of 1,7-Dimethyl-9-phenyl-9-phenyl-pseudo-uric Acid.—Sixty cc. of N potassium hydroxide solution was cooled to 0°, 5 g. of finely powdered dimethyl-uramil was added, and the mixture shaken until all the solid had dissolved. A violet solution resulted. To this, 3.8 g. of phenyl isocyanate was added in small portions, and the solution shaken vigorously after each addition until it became odorless. The temperature was kept at 0-2°. The color deepened and the solution became slightly cloudy. The addition required about half an hour. The mixture was filtered, and the filtrate when acidified with dil. hydrochloric acid gave a heavy, white precipitate (8 g.); m. p., 220°. It was difficultly soluble in water, about 350 cc. of solvent being necessary to dissolve 1 g. A fine, white product was obtained, which turned pink at 160°, light yellow at 210°, and melted at 220° to an orange-red liquid. It was dried in a vacuum over sulfuric acid for analysis.

Analyses. Subs., 0.1551, 0.1533: N, 27.2 cc. (23°, 756.8 mm.), 26.9 cc. (26°, 767.5 mm.). Calc. for C₁₃H₁₄O₄N₄: N, 19.32. Found: 19.57, 19.44.

OPTICAL PROPERTIES.—Habit, small, hexagonal plates; symmetrical extinction,  $\alpha$  parallel to elongation; birefringence, strong; indices,  $\alpha = 1.555$ ,  $\gamma = 1.695$ .

Preparation of 1,7-Dimethyl-9-phenyl-uric Acid.—Five g. of the pseudo acid was dissolved in 1 liter of 20% hydrochloric acid and the solution boiled over a free flame until crystallization began. It was then evaporated on the steam-bath to 1/3 its volume, cooled and filtered. About 3 g. of material was obtained. It did not melt below 280°. The filtrate, on further evaporation, gave 0.8 g. more. The total yield was 3.8 g., or 80%. On recrystallization from water it was obtained as a fine, glistening, white powder. It was dried at 100–110° for analysis.

Analyses. Subs., 0.2796: CO₂, 0.5866; H₂O, 0.1035. Subs., 0.1460, 0.1280: N, 27.1 ec. (22°, 756.8 mm.), 23.0 ec. (21°, 765.2 mm.). Cale. for  $C_{13}H_{12}O_3N_4$ : C, 57.32; H, 4.44; N, 20.60. Found: C, 57.22; H, 4.23; N, 20.83, 20.50.

Optical Properties.—Habit, long, rectangular and hexagonal plates; extinction, symmetrical,  $\gamma$  parallel to elongation; indices,  $\alpha=1.540, \, \gamma>1.755$ .

Action of Alkali.—A solution of 0.2 g. of dimethyl-phenyl-uric acid in 12 cc. of 4 N sodium hydroxide was boiled for 10 minutes. When the solution was partly cooled and acidified, an immediate heavy precipitate of the unchanged acid, weighing 0.18 g., was obtained. It did not melt below 280°.

Methylation of 7-Methyl-9-phenyl-uric Acid.—One g. of 7-methyl-9-phenyl-uric acid was dissolved in 20 cc. of 2 N sodium hydroxide solution. Two g. of dimethyl sulfate was added, and the flask closed with a cork and shaken for 15 minutes while it was cooled with running water. A precipitate gradually separated and after 1 hour was filtered off. It weighed 0.1 g.; m. p., 258-259°. It was 1,3,7-trimethyl-9-phenyl-uric acid as a comparison of melting points and optical properties showed. When the

¹⁴ Biltz, Ber., 46, 3671 (1913).

¹⁵ Fischer, Ber., 33, 1708 (1900).

filtrate was acidified, an immediate heavy, white precipitate formed, which weighed 0.5 g. It did not melt below 280° and its optical properties were identical with those of 1,7-dimethyl-9-phenyl-uric acid.

#### Summary

- 1. The action of alkali on 1,3-dimethyl-9-phenyl-uric acid has been studied, and the course of the reaction and the nature of the decomposition products have been determined.
- 2. The primary decomposition product is 3-phenyl-isohydantoin-5-carboxylic acid methylamide. This is further decomposed by alkali to methylamine, oxalic acid, glycolic acid, formic acid and phenylurea.
- 3. Phenylisohydantoin-carboxylic acid methylamide is oxidized by hydrogen peroxide to 3-phenyl-5-hydroxyhydantoin-5-carboxylic acid methylamide, which is readily decomposed by alkali to mesoxalic acid, methylamine and phenylurea.
- 4. 1,7-Dimethyl-9-phenyl-uric acid, and the ethyl ester and methyl-amide of phenyl-oxaluric acid have been prepared for the first time and characterized.
- 5. The action of alkali on other substituted uric acids is now being investigated.

#### DERIVATIVES OF CAMPHORONIC ACID

By Walther F. Goebel with William A. Noyes¹ Received August 25, 1923

#### Introduction

Despite the fact that camphoronic acid and many of its derivatives have been known since the latter part of the nineteenth century, no direct proof for the special structures of these derivatives has ever been brought forward. Kachler² first discovered camphoronic acid in the mother liquors of a camphor-nitric acid oxidation mixture; the true structure of the acid was first suggested by Bredt³ and later confirmed by the classical synthesis of inactive camphoronic acid by Perkin and Thorpe.⁴

Of the derivatives studied in this research there are already known one anhydro acid,  5  C₆H₁₁(CO)₂OCOOH, two isomeric anhydro acid chlorides,  6

 $C_6H_{11}(CO)_2OCOCl$ , one diethyl ester,⁷  $C_6H_{11}(COOC_2H_5)_2COOH$ , one mono ethyl ester,⁸  $C_6H_{11}(COOC_2H_5)(COOH)_2$ , one acid imide,⁹  $C_6H_{11}(CO)_2NHCOOH$ , and two isomeric anhydrobromo acid chlorides,¹⁰  $C_6H_{10}$ -Br(CO)₂OCOCl, in which it is known that the bromine is on the primary carbon atom.

It was the original purpose of the present investigation to establish the structures of the various derivatives of camphoronic acid. The method of attack was planned as follows. If one of the anhydro acid chlorides were to be treated with anhydrous ammonia, the corresponding anhydro-amide should be formed, which on treatment with sodium hypobromite should then yield the corresponding dibasic amino acid. This compound on treatment with nitrous acid should give a dibasic hydroxy acid. If the hydroxyl group were on the primary carbon atom, trimethyl paraconic acid, a known compound would result. If it were, however, on the carbon atom bearing the two methyl groups, an isomeric lactone should result; while if the hydroxyl group were on the central carbon atom, no lactone could be produced. In this way it was hoped that the structures of the parent substances could be proved.

#### Discussion

The formation of isomeric imides, when it was desired to prepare the amides from the corresponding anhydrocamphoronyl chlorides, proved, however, to be the unavoidable obstacle presented in the outline of attack set forth above. It was shown that, from the weight of ammonia absorbed and the percentage of inorganic and organic nitrogen present, both isomeric anhydro-acid chlorides of camphoronic acid, when treated with ammonia, form an anhydro amide. The failure to obtain an indication of the reaction of the latter with sodium hypobromite to produce the corresponding amino acid may be attributed to one of two causes: either the anhydro amide actually reacted with the hypobromite according to the scheme

$$C_{6}H_{11} \stackrel{CO}{\underset{COON_{2}}{\bigcirc}} + 2NaOH = C_{6}H_{11} \stackrel{COONa}{\underset{COON_{2}}{\bigcirc}} + H_{2}O \qquad (1)$$

$$C_{6}H_{11} \stackrel{COONa}{\underset{COON_{2}}{\bigcirc}} + NaOH = C_{6}H_{11} \stackrel{COONa}{\underset{COON_{1}}{\bigcirc}} + NaOH \qquad (2)$$

$$C_{6}H_{11} \stackrel{COONa}{\underset{COON_{2}}{\bigcirc}} Br = C_{6}H_{11} \stackrel{COONa}{\underset{COON_{3}}{\bigcirc}} + NaOH \qquad (3)$$

or the anhydro amide rearranged to the more stable imidic acid structure the moment it passed into solution.

⁷ Ref. 3, p. 100.

⁸ Ref. 3, p. 104.

⁹ Hess, Ber., 28, 2689 (1895).

¹⁰ Bredt, Ann., 299, 142 (1898).

It is, of course, improbable that evidence for the above reactions can be secured. On the other hand, the unusual inactivity of both isomeric imides toward even strong alkali indicates clearly the great stability of the imide structure, while the isolation of the imide instead of the anhydro-amide on extraction of the precipitate of ammonia and anhydro acid chloride with anhydrous solvents seems to leave little doubt as to the instability of the latter compound.

The results of these researches have clearly shown the futility of an attempt at the preparation of either a dibasic amide or an anhydro amide of camphoronic acid which can be made to react with sodium hypobromite. The results, furthermore, demonstrate the necessity of covering two carboxyl groups more effectively than by forming a dimetallic salt if it is desired to prepare such a compound. The great stability of the imide seemed to indicate that a most desirable "covering group" had been found. With this in mind the attempted preparation of isomeric imide-amides from the corresponding imides was undertaken, with most gratifying results. Both imide-amides have been found to react with sodium hypobromite even in the cold, and it is through these compounds that the original plan of attack set forth in the beginning of the paper, though modified, may be brought to a satisfactory conclusion.

## Experimental Part

Preparation of Pure Camphoronic Acid.—In a 12-liter flask fitted with a condenser made from a glass tube slightly smaller than the neck of the flask, sealed at the bottom, and bearing an entrance and exit tube for water, was placed 2 kg. of camphor. was added 10 kg. of concd. nitric acid, and the mixture was gradually heated to boiling. After two weeks' continuous boiling, when the relative yield of camphoronic and camphoric acids was found to be greatest, the mixture was cooled, the camphoric acid filtered off and the mother liquor evaporated on the water-bath. The residue, which consisted of a sticky paste, was dissolved in an equal volume of hot water, the solution placed in a flask on a water-bath, and a blast of air bubbled through for two days to remove the last traces of nitric acid. (Inorganic salts, which would be formed by the neutralization of the excess of nitric acid with sodium or ammonium hydroxides, were found to inhibit materially the precipitation of barium camphoronate.) This residue was diluted with an equal volume of water and an excess of barium hydroxide, previously dissolved in water, was added. The mixture was stirred with a mechanical device and gradually heated to boiling. A cream-white, sandy precipitate of barium camphoronate resulted which was filtered off, washed, and redissolved in dil. hydrochloric acid. The solution was then boiled with 15 g. of Norite, filtered and boiled again. This was repeated eight times. The barium camphoronate was finally reprecipitated by the addition of ammonia to the neutral point, followed by boiling. Without cooling the mixture the barium salt was filtered off, washed, re-dissolved in dil. hydrochloric acid, boiled with Norite and again reprecipitated. This process was repeated four times. The final product was white barium camphoronate. The salt was again dissolved in hydrochloric acid, the barium precipitated from boiling solution by the addition of a slight excess of dil. sulfuric acid, and the filtrate evaporated to a small volume by distillation under reduced pressure. (The presence of a large excess of hydrochloric acid is desirable for it aids in the crystallization of camphoronic acid.) After standing for twelve hours the yellow mother liquors, containing about 200 g. of camphoronic acid, were filtered from 280 g. of crystalline, snow-white camphoronic acid. Recrystallization from an equal weight of water yielded fine needles melting at 164–165° when the bath was raised 1° per second from 150°. The acid in the mother liquors was recovered, after evaporation, as its barium salt.

Anhydrocamphoronic Acid was prepared in quantitative yields by heating the pure acid under reduced pressure in a distilling bulb immersed in oil at 180°. A waterwhite liquid was obtained, which solidified and then melted when the bath was raised to 133°. Recrystallization from chloroform yielded snow-white crystals melting at 139°;  $|\alpha|_{D}^{20} = +5.56$ ° (in chloroform).

Anhydrocamphoronyl Chlorides were prepared and separated by the method of Kachler and Spitzer. Instead of heating the mixture of phosphorus pentachloride and anhydrocamphoronic it was allowed to stand at room temperature. The  $\alpha$  chloride (m. p., 137–138°;  $[\alpha]_D^{20} = +6.25$ °, in chloroform) was obtained in yields of 43%. The  $\beta$  chloride (m. p., 38–39°;  $[\alpha]_D^{20} = -4.21$ °, in chloroform) was obtained in yields of 48%.

Mono-ethyl Camphoronate.—The mono-ester of camphoronic acid has been prepared hitherto only from the anhydro-ester by permitting the latter to stand with water for a considerable length of time. It has been found possible to prepare this compound by the direct esterification of the acid. Camphoronic acid was treated with 1.7 times its weight of absolute alcohol. Dry hydrogen chloride was passed in until present to the extent of 3% of the total weight of the mixture. After standing for 18 hours at room temperature the mixture was diluted and evaporated, and the crystals of mono-ester were filtered off. Recrystallization from water gave transparent crystals; m. p., 139–140°;  $[\alpha]_{0}^{20} = -30.21$ °, in absolute alcohol. The ester group in this compound is undoubtedly on the primary carboxyl group.

Analysis. Calc. for C11H18O6: C, 53.61; H, 7.37. Found: C, 53.75; H, 7.24.

The diester was separated according to the method of Bredt.⁷ Its purity was ascertained by titration;  $[\alpha]_D^{20} = -9.91^{\circ}$ , in absolute alcohol.

The Bromo-anhydrocamphoronyl Chlorides.—The preparation of these compounds was carried out exactly as Bredt¹⁰ describes, except that the bromination was catalyzed by the addition of a small amount of iron filings, followed by heating for one hour. A yield of 78% of the  $\alpha$  isomer was obtained;  $[\alpha]_0^{20} = -6.29^\circ$ , in chloroform.

Action of Ammonia and  $\alpha$ -Anhydrocamphoronyl Chloride.—In an attempt to prepare the anhydro-amide of camphoronic acid 4.85 g. of  $\alpha$ -chloride in benzene at 10° was treated with an excess of anhydrous ammonia. A precipitate resulted which, after the excess of ammonia was swept away, was filtered, dried, dissolved in water, acidified with dil. hydrochloric acid, and extracted with ether. The dried ether extract yielded 4.53 grams of solid; m. p., 196–200°. Recrystallization from hot water gave transparent crystals; m. p., 199.4–200.2°;  $[\alpha]_p = -6.86$ °, in absolute alcohol; repeated recrystallization failed to raise the melting point.

Analyses. Calc. for C9H13O4N: N, 7.03. Found: 6.99, 7.15.

Acid number. Calc. for C₆H₁₁ CO NH: 281. Found: 282.

This compound was found to be identical with the imide prepared by Hess¹¹ from the anhydro acid.

To ascertain whether the acid chloride group or the anhydride group had reacted with ammonia, 0.9670 g. of  $\alpha$  chloride was placed in a weighed bulb, dry benzene added to dissolve the chloride, the solution cooled to 10°, and anhydrous ammonia passed in

¹¹ Ref. 9. p 2687.

until no further precipitate resulted. The solvent was evaporated after the excess of ammonia was blown out with dry air, and the bulb dried to constant weight. An increase in weight of 0.1860 g. had resulted, or approximately 2.4 molecular equivalents of gas had reacted. The total percentage of nitrogen was found to be 12.05, and the ammonium nitrogen 6.80%. There was then left 5.25% of organic nitrogen. In a 1:1 mixture of anhydro amide (or acid imide) and ammonium chloride the organic nitrogen content should be 5.55%. This experiment shows conclusively that the acid chloride and not the anhydride group had reacted. The presence of 0.4 molecular equivalents' excess of ammonium nitrogen is explained by the fact that a partial rearrangement of the anhydro amide to the acid imide had occurred, which in turn reacted with more ammonia to form the ammonium salt of camphoronimide.

In the hope of securing an anhydro-amide the precipitate was placed in a dried Soxhlet thimble and extracted with anhydrous chloroform. Despite the fact that water was absent and solution resulted, rearrangement to the imide had been complete, for only an imide was recovered from the chloroform extract.

In every way the  $\beta$ -chloride behaved as did its isomer. With ammonia, however it yielded in benzene solution an imide which, hitherto, has not been prepared. The imide, on crystallization from water, yielded transparent crystals; m. p., 234.5-235°;  $[\alpha]_{p}^{20}$  = -5.40°, in absolute alcohol.

Analyses. Calc. for 
$$C_0H_{10}O_4N$$
: N, 7.03. Found: 7.01, 7.12. Acid number. Calc. for  $C_0H_{11}$  CONH: 281. Found: 283.

It was hoped that the two isomeric imides could be hydrolyzed to the acid amide by alkali. Heating at 100° for 25 hours with three molecular equivalents of N potassium hydroxide produced, not hydrolysis to the amide, but a 2% hydrolysis to camphoronic acid in the case of the  $\alpha$ -imide and a 20% hydrolysis in the case of the  $\beta$ -imide.

The Action of Anhydrous Ammonia on α-Anhydrobromo-camphoronyl Chloride.— In the hope of preparing an amide of α-anhydrobromo-camphoronyl chloride the pure crystals were treated in benzene solution at 10° with an excess of dry ammonia. After the dissolved gas had been swept away the benzene was evaporated, the residue was dissolved in dil. hydrochloric acid and repeatedly extracted with ether. was obtained, which, after recrystallization from water, melted at 220°.

The Action of Sodium Hypobromite on the Reaction Product of Anhydrous Ammonia and α- and β-Anhydrocamphoronyl Chlorides.—Experiments were carried out in which both isomeric anhydro chlorides were treated at 10° in benzene solution with dry ammonia, the excess of gas was swept away and the suspended precipitate treated with six molecular equivalents of 10% sodium hydroxide solution in which was dissolved the calculated amount of bromine. In each case, after the mixture had been heated on the water-bath for one hour, acidification with hydrochloric acid produced no evolution of carbon dioxide. An ether extraction yielded an almost quantitative recovery of the corresponding imide. The aqueous layer, after evaporation to complete dryness, gave but a trace of organic matter when extracted with absolute alcohol.

The Action of Ammonia on Mono-ethylcamphoronate. - In an attempt to prepare the mono-amide of camphoronic acid, 10 g. of an absolute alcoholic solution of mono-ester was treated with 3 molecular equivalents of dry ammonia dissolved in the same solvent. The mixture was placed in a Pyrex tube, sealed, and heated for four days at 140°. At the end of this time the tube was opened, the alcohol distilled in a vacuum, and the residue acidified and extracted with ether. A nitrogenous solid weighing 8.5 g. was obtained. Unchanged ester (0.5 g.) was dissolved from the pulverized solid with small amounts of chloroform. The residue was crystallized from hot water. A nitrogenous acidic solid was obtained; m. p.,  $199-200^{\circ}$ . This compound proved to be identical with the imide prepared from the  $\alpha$ -chloride.

The Action of Anhydrous Ammonia on Disodium Ethylcamphoronate,—A sample of  $4.82~\rm g$ . of mono-ester was heated at  $140^{\circ}$  with 1.95 molecular equivalents of sodium ethylate in a Pyrex tube for four days. A crystalline precipitate weighing  $0.90~\rm g$ , was filtered from the liquid portion at the end of the heating. This compound did not yield its nitrogen when heated with 10% alkali.

Analyses. Calc. for C6H11(CO)2NNa.COONa: N, 5.76. Found: 6.04, 5.85.

In the belief that the disodium amide was in the mother liquors, the latter were evaporated and a crystalline precipitate weighing 4.87 g. and containing 1.69% of nitrogen was obtained. When the precipitate was treated with sodium hypobromite and alkali in proper proportions, heated for one hour, cooled and acidified, no evolution of gas was observed. An ether extract yielded 4.01 g. of solid which proved to be about 25% of imide and 75% of unchanged ester.

Preparation of  $\alpha$ -Camphoronamide-imide.—A sample of  $\alpha$ -camphoronimide weighing 14.63 g. was treated with 1.2 molecular equivalents of phosphorus pentachloride. As the mixture failed to evolve hydrogen chloride, the distilling bulb containing the two substances was heated on the water-bath for an hour. At the end of this time practically all of the phosphorus pentachloride had disappeared. The phosphorus oxychloride was distilled under a vacuum. The residue, weighing 16.36 g. and consisting of a viscous yellow oil, was dissolved in absolute ether and the solution cooled to  $-20^{\circ}$ . Ligroin, at the same temperature, was added carefully. A cloud, but no crystals, appeared. One or two drops of ether were added to clear the cloud and the mixture was allowed to stand for three days at this temperature. No crystals appeared in the solution, so an excess of anhydrous ammonia was passed into the mixture. A white precipitate resulted which was filtered from the mother liquors. The latter gave only a trace of organic matter on evaporation.

The precipitate was mixed with a small amount of water and dried by suction to remove ammonium chloride. The residue was dissolved in a small amount of boiling water, the solution boiled with a little Norite, filtered, and the filtrate allowed to cool. Transparent crystals were obtained; m. p.,  $235-236^{\circ}$ ;  $[\alpha]_{541.6}^{280} \mu\mu = +11.87^{\circ}$ , in absolute methyl alcohol.

Analysis. Calc. for C9H14O2N2: N, 14.13. Found: 13.89.

Preparation of the Acid Chloride of  $\beta$ -Camphoronimide.—To 12.02 g. of  $\beta$ -camphoronimide, in a small distilling bulb, was added 1.2 molecular equivalents of pulverized phosphorus pentachloride, and the mixture warmed on the water-bath for one hour. At the end of this time glistening crystals, quite unlike the imide, precipitated from the mixture as it cooled. After distillation of the phosphorus oxychloride under a vacuum, the residue, weighing 14.3 g., was washed well with absolute ether; 11 g. of solid was obtained. This compound, on analysis, proved to be the acid chloride of the  $\beta$  imide. It was found to be very soluble in chloroform and in hot benzene. When recrystallized from the latter a beautiful solid product was obtained; m. p., 175.5–176.5°;  $\alpha$ 16.1°  $\alpha$ 16.1°  $\alpha$ 16.1°  $\alpha$ 17.6°  $\alpha$ 18.32°, in chloroform.

Analyses. Calc. for C₉H₁₂O₃NC1: N, 6.43; Cl, 16.31. Found: N, 6.18; Cl, 16.20.

Preparation of  $\beta$ -Camphoronimide-amide.—An excess of anhydrous ammonia was passed into a chloroform solution of 5.2 g. of the  $\beta$ -imide acid chloride, the excess of gas was swept away, the solvent evaporated, and the solid precipitate washed with a

small amount of water to remove ammonium chloride. The residue was dissolved in boiling water, the solution filtered and allowed to cool. Transparent crystals of the  $\beta$ -imide-amide were obtained; in. p., 205°;  $[\alpha]_{541.6\mu\mu}^{1289} = -13.73$ °, in absolute acetone.

Analysis. Calc. for C9H14O3N2: N, 14.13. Found: 13.95.

# Summary

- 1. Anhydrocamphoronic acid has been prepared in quantitative yields.
- 2. Mono-ethyl camphoronate has been prepared by the direct esterification of the acid in yields of 50%.
- 3. Monomethyl camphoronate yields an imide on treatment with ammonia at 140°. This imide is identical with that obtained from the anhydro acid under similar treatment.
- 4. Anhydrous ammonia reacts with  $\alpha$ -anhydrocamphoronyl chloride to yield first an anhydro amide and then an acid imide by rearrangement. This imide is identical with that obtained from the mono-ester.
- 5. Anhydrous ammonia reacts with  $\beta$ -anhydrocamphoronyl chloride in a similar manner to form an isomeric imide. This compound is new in the camphoronic acid series.
- 6. Anhydrous ammonia reacts with bromo-anhydrocamphoronyl chloride to form a bromo-imide. This compound is new in the camphoronic acid series.
- 7. Potassium hydroxide fails to open the ring of either  $\alpha$  or  $\beta$ -camphoronimide to yield a dibasic amide. In each case partial hydrolysis to the parent acid is the only reaction involved.
- 8. When the reaction product of anhydrous ammonia and  $\alpha$ -anhydrocamphoronyl chloride, or  $\beta$ -anhydrocamphoronyl chloride, or disodium ethylcamphoronate is treated with sodium hypobromite the corresponding amino acid is not formed. In each case an imide is produced.
- 9. When  $\alpha$ -camphoronimide is treated first with phosphorus pentachloride and then with anhydrous ammonia an imide-amide of camphoronic acid is produced. This compound is new in the camphoronic acid series. The compound reacts readily with sodium hypobromite.
- 10. The acid chloride of  $\beta$ -camphoronimide has been prepared. This compound is new in the camphoronic acid series.
- 11. When the acid chloride of  $\beta$ -camphoronimide is treated with anhydrous ammonia an amide is formed. This amide is isomeric with that prepared from the  $\alpha$ -imide, is new in the camphoronic acid series, and reacts readily with sodium hypobromite.

# STUDIES IN THE DIPHENIC ACID AND IN THE FLUORENONE SERIES. I

By H. W. Underwood, Jr., and E. L. Kochmann¹
Received September 5, 1923

Phenolphthalein, fluorescein and gallein are prepared by well-known methods which involve the condensation of phthalic anhydride with phenol, resorcinol and pyrogallol, respectively. A part of this paper

is an account of results obtained by using diphenic anhydride,  $\begin{array}{c} & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ &$ 

and allied compounds in place of phthalic anhydride in these processes. Sulfuric acid is frequently employed as a condensing agent in the synthesis of fluorescein. On account of the fact that sulfuric acid transforms diphenic anhydride into the isomeric diphenyleneketone-4-carboxylic acid,  $C_6H_4$ 

 $C_6H_3$ — $C_9H$ 

chloride as dehydrating agents in our work. Equations for the condensations with phenol and with resorcinol might be written as follows:

The crystalline substance obtained from the phenol reaction did not give a red solution when it was dissolved in caustic alkali, nor did the sodium salt of the crystalline compound isolated from the resorcinol-anhydride condensation show fluorescence in solution. However, the amorphous residue from Reaction 1 behaved like phenolphthalein and that from Reaction 2 showed properties similar to those of fluorescein. Consideration of these results caused us to believe that the dehydrating agents employed might have changed a part of the diphenic anhydride into diphenyleneketone-4-carboxylic acid and that the ketone oxygen of the latter had reacted with two atoms of ring hydrogen from two molecules of phenol

¹ The experimental results described in this paper are taken from a thesis submitted to the Faculty of the Massachusetts Institute of Technology by E. L. Kochmann in partial fulfillment of the requirements for the degree of Bachelor of Science.

or of resorcinol to yield substances respectively colored or fluorescent in alkaline solution. The formula for the sodium salt of the phenol reac-

Experiments were carried out to test the validity of these ideas. It is customary to explain the red color of phenolphthalein in alkaline solution by saying that a quinoid ring is formed; this phenomenon is also said to be involved in salt formation by fluorescein. If salts having formulas analogous to that given above are responsible for the color and fluorescence obtained in our experiments, then we have instances of indicator effects and of fluorescence which do not involve quinoid ring formation. To secure further evidence on this point, we have condensed fluorenone with phenol and with resorcinol² on the supposition that the oxygen atom in this ketone would unite with two atoms of ring hydrogen from two molecules of phenol or of resorcinol. The remainder of our research consists of an investigation of the value of the bromine derivative of the resorcinol-diphenyleneketone-4-carboxylic acid compound and of the pyrogallol-diphenic anhydride condensation product as dyes.

After a considerable part of this work had been completed two articles which mentioned reactions of diphenic anhydride were published. Dutt³ described phenoldiphenein and resorcinoldiphenein and Bischoff and Adkins⁴ dealt with the latter as well as the reaction between diphenylene-ketone-4-carboxylic acid and resorcinol. Apparently all of these investigators ascribe the production of color and fluorescence in alkaline solutions to the diphenic anhydride condensation products, and they do not touch upon the transformation of diphenic anhydride into the isomeric ketone acid by the condensing agents they employed. The differences between our results and those obtained by Dutt and by Bischoff and Adkins with regard to this matter, and in other respects, are brought out in the description of our experiments and in the summary of this paper.

# Discussion of Experiments

All of the temperatures given below are uncorrected.

Diphenic Anhydride.—In order to ascertain whether diphenic acid could be transformed into the anhydride by heat, samples of the material were maintained at temperatures 10° above its melting point for half

² Experiments involving some of these reactions of fluorenone and of diphenylene-ketone-4-carboxylic acid were performed long ago by Graebe and Aubin [Ann., 247, 257 (1888)].

³ Dutt, J. Chem. Soc., 123, 225 (1923).

⁴ Bischoff and Adkins, This Journal, 45, 1030 (1923).

an hour. Examination of the product showed that no diphenic anhydride had been formed.

Subsequently, the following procedure was adopted.

Mixtures of diphenic acid, acetic anhydride and glacial acetic acid (solvent) were heated at  $145^{\circ}$ , then allowed to cool, the crystalline solid was collected on a filter and the filtrate poured into water in order to obtain any material held in solution. All of the solid reaction products were treated with a cold 20% solution of sodium carbonate to remove diphenic acid. Results are given below.

Diphenic acid G.	Acetic anhydride G.	Calc. amt. X	Acetic acid G.	Time of heating hours	Diphenic anhydride G.	Vield
10	20	4.8	20	0.50	8.7	94.0
25	50	4.8	50	1.25	21.5	92.9
25	11.5	1.1	45	1.25	18.5	79.9
15	9.4	1.5	27	1.00	12.1	87.1
15	12.6	2.0	27	1.00	12.2	87.9
15	15.7	2.5	25	1.00	12.65	91.1
30	31.4	2.5	50	2.00	24.7	89.0

These experiments produced diphenic anhydride which melted at 222-224°.

Phenol and Diphenic Anhydride.—Twenty-one g. of phenol (calc. amt. × 2.7), 10 g. of diphenic anhydride and 16 g. of fuming stannic chloride were placed in a round-bottom flask provided with an air condenser and heated at 130-135° for 15 hours. Steam distillation was employed to remove excess of phenol. The solid reaction product was collected on a filter, dried and finely powdered. Treatment with (1) a 50% solution of sodium bicarbonate showed that none of the condensation product was soluble in this medium. Repeated extractions with (2) ammonium hydroxide, with (3) sodium carbonate solution and with (4) 3 N sodium hydroxide solution followed by acidification of the extract liquors and washing and drying of the precipitates thereby produced, gave amorphous brown or cream-colored powders having the following weights: (2) 11.56 g., (3) 0. g., (4) 2.9 g. The ammonium hydroxide used in these extractions was prepared by mixing equal volumes of material having a density of 0.90 and water; the sodium carbonate solution was 50%. Solutions of these concentrations and others given above were employed in all of the experiments described in this paper. When the several alkaline liquids were made acid, the solids formed as gelatinous precipitates which held inorganic salts very tenaciously. It was necessary to grind the dried powders repeatedly with water in order to remove the sodium chloride which was mixed with them. By the use of glacial acetic acid as a solvent, colorless rhombic crystals (m. p., 250-251°) were obtained from the portion of the condensation product soluble in ammonium hydroxide; 2.7 g. of crystals was obtained from 5 g. of crude material. These crystals gave a yellow solution in sodium hydroxide, but the amorphous powder produced by dilution of the acetic acid filtrate dissolved in aqueous sodium hydroxide with a deep red color. Dutt3 described phenoldiphenein as pinkish white needles (from dil. alcohol, m. p., 134°, containing 2 molecules of water of crystallization) which dissolved in sodium hydroxide solution with a reddish-pink color.

Analyses (crystals, m. p., 250-251°). Calc. for C₂₆H₁₈O₄: C, 79.16; H, 4.60. Found: C, 78.74, 78.80; H, 5.02, 5.09.

We intend to investigate the acetyl derivative of phenoldiphenein; preliminary experiments indicate that it is insoluble in cold caustic alkali solutions.

Resorcinol and Diphenic Anhydride.—Twenty g. of fused and finely divided zinc chloride was gradually added to a mixture of 25 g. of resorcinol (calc. amt. × 1.27) and 20 g. of diphenic anhydride stirred and maintained at 175°. The total time of heating was 4 hours. After the dark red melt had cooled, it was powdered, boiled with dil. hydrochloric acid, drained on a filter and dried. It was then washed thoroughly with water, treated with a 50% solution of sodium hydroxide and the undissolved material collected on a filter. Acidification of the alkaline liquid yielded a brown precipitate which weighed 25.5 g, when washed and dried. To an almost neutral solution of this material in aqueous sodium hydroxide an excess of lead acetate solution was added and the lead lake thereby produced was removed by filtration. After drying the latter, it The finely powdered lead compound was suspended in alcohol and weighed 50.4 g. treated with an excess of hydrogen sulfide. After removal of the lead sulfide, the alcoholic solution of the condensation product was evaporated to dryness or diluted with water to obtain the crude resorcinoldiphenein which came down as a reddish-brown powder (weight when dry, 22 g.). A filtered solution of the latter in hot alcohol was carefully diluted with water until a slight precipitate appeared, and then warmed and allowed to stand. Almost colorless crystals were thereby obtained, which melted at 178-179° when dry; 1.9 g. of crystals was secured from 5 g. of crude material. These crystals dissolved in sodium hydroxide solution to yield a yellow liquid with practically no fluorescence. The brown, amorphous powder obtained by concentration of the alcoholic solution gave a strongly fluorescent solution when dissolved in aqueous sodium hydroxide.

According to statements made by Dutt,³ resorcinoldiphenein forms brown prisms (from dil. alcohol), m. p., 172°, which show a brilliant green fluorescence when dissolved in caustic alkalies. He gave the formula as  $C_{26}H_{16}O_5$ . Although Bischoff and Adkins⁴ did not report a quantitative analysis of resorcinoldiphenein for carbon and hydrogen, they concluded from a determination of the metal content of the sodium salt, which they write as  $C_{26}H_{14}O_5Na_4$ , that the oxygen bridge present in the original compound is opened by dissolving the material in sodium hydroxide solution.

Analyses (crystals, m. p., 178-179°). Calc. for C₂₆H₁₈O₆: C, 73.22; H, 4.25. Found: C, 72.94, 73.00; H, 4.55, 4.45.

Pyrogallol and Diphenic Anhydride.—A mixture of 7 g. of pyrogallol (calc. amt. × 1.25), 5 g. of diphenic anhydride and 8 g. of fuming stannic chloride was heated at 125–130° for 7 hours. The mass was cooled and diluted with water. Subsequent treatment of the product was the same as that employed in the case of the phenol condensation, except that the steam distillation was omitted. Yields were as follows: none of the material was soluble in (1) sodium bicarbonate or in (2) ammonium hydroxide; (3) sodium carbonate extract, 4.2 g. of a black powder; (4) sodium hydroxide extract, 4.4 g. of a black powder. None of these materials melted at 325°, and they were practically insoluble in all of the usual organic solvents as well as nitrobenzene, aniline and quinoline. We did not succeed in getting these substances pure enough for accurate analyses.

Diphenyleneketone-4-carboxylic Acid from Diphenic Anhydride.—Five g. of diphenic anhydride and 7 g. of anhydrous stannic chloride were heated at 120–130° for 7 hours. The cold reaction product was poured into water, filtered and washed. It was found to be completely soluble in a 50% solution of sodium carbonate. When the latter was acidified, it yielded a yellow precipitate. This was identified as diphenyleneketone-4-carboxylic acid by a mixed-melting-point with some of the ketone acid prepared by treating diphenic acid with sulfuric acid.⁵ Evidently the stannic chloride transformed all the diphenic anhydride into the isomeric diphenyleneketone-4-carboxylic acid.

⁵ Graebe and Mensching, Ber., 13, 1302 (1880).

Similar results were obtained by maintaining a mixture of 5 g. of diphenic anhydride and 4 g. of anhydrous zine chloride at 225° for 8 hours.

Diphenic Anhydride from Diphenyleneketone-4-carboxylic Acid.—A mixture of 5 g. of diphenyleneketone-4-carboxylic acid, 10 g. of acetic anhydride and 5 cc. of glacial acetic acid was heated at  $140-150^{\circ}$  for 6 hours. The solid reaction product obtained when this mixture was cooled, diluted with water and filtered, was treated twice with a 50% solution of sodium carbonate. The undissolved residue upon recrystallization from benzene formed needles (0.9 g.) which melted at  $222^{\circ}$ . This was identified as diphenic anhydride by a mixed-melting-point with some anhydride of known purity. Apparently diphenyleneketone-4-carboxylic acid can be changed into diphenic anhydride, but the process is very slow.

Phenol and Diphenyleneketone-4-carboxylic Acid.—A mixture of 10 g. of phenol, 5 g. of diphenyleneketone-4-carboxylic acid and 8 g. of fuming stannic chloride was maintained at 120–125° for 5 hours. Subsequent treatment of the product was the same as that employed in the case of phenoldiphenein. Yields were as follows: none of the product dissolved in (1) sodium bicarbonate solution or in (3) sodium carbonate solution; (2) ammonium hydroxide extract, 4.5 g. of a salmon-red powder (m. p., 180–185°); (4) sodium hydroxide extract, 1.05 g. of reddish-brown material (m. p., 213–220°).

Analyses. Calc. for  $C_{20}H_{18}O_4$ : C, 79.16; H, 4.60. Found: C, 78.63, 78.70; H, 5.1, 5.13.

Resorcinol and Diphenyleneketone-4-carboxylic Acid.—A mixture of 7 g. of resorcinol (calc. amt. × 1.4), 5 g. of diphenyleneketone-4-carboxylic acid and 18 g. of fuming stannic chloride was heated for 10 hours at 120–130°. The method used for working up the reaction mass was similar to that already described for the phenol-diphenic anhydride condensation product. The yields were: (1) sodium bicarbonate extract, 1.3 g. of an amorphous substance (m. p., 215–240°); (2) material soluble in ammonium hydroxide, 6.7 g. (did not melt at 325°); (3) sodium carbonate extract, 0 g.; (4) a substance removed by sodium hydroxide solution, 0.5 g. (this remained solid at 325°). All of these materials were brown or red amorphous powders which gave a deep green fluorescence when dissolved in caustic alkali solution. Analyses were made of samples obtained directly from the reaction product by treatment with sodium hydroxide solution. The material was subsequently dissolved in alcohol, filtered and the alcohol-soluble portion obtained by dilution with water; this treatment was repeated several times.

Analyses.⁶ Calc. for C₂₆H₁₈O₆: C, 73.22; H, 4.25. Found: C, 72.87, 72.79; H, 4.61, 4.7.

It is planned to investigate the acetyl derivatives of this condensation product as well as the one obtained from phenol; preliminary experiments indicate that the acetyl compounds are soluble in cold sodium hydroxide solution.

Phenol and Fluorenone.—In an Erlenmeyer flask 3.5 g. of fluorenone and 5.5 g. of phenol (50% excess) were mixed with 9 g. of fuming stannic chloride, and the whole was then heated at  $130-140^{\circ}$  for 6 hours. After cooling the mass, it was steam distilled to

⁶ It was found impossible to burn this compound, as well as several others produced in our work, in ordinary combustion tubing. Consequently, for all the carbon-hydrogen determinations mentioned in this paper we used tubes made of fused silica, mixed the compounds intimately with fine copper oxide and burned them in a current of oxygen during the course of 8 to 10 hours. Special precautions were taken with regard to the hygroscopicity of fine copper oxide, and in some cases hydrogen was determined separately. Every compound analyzed was previously dried at 110° to constant weight.

remove excess of phenol, then filtered and treated with 3 N sodium hydroxide solution. When the latter was acidified a salmon-red precipitate was obtained which weighed 4.1 g. after it had been washed and dried, and melted incompletely at 241–243°. This substance dissolves in sodium hydroxide and forms a deep red solution. A portion was several times dissolved in hot alcohol, separated from impurities by filtration and recovered by dilution of the alcoholic solution with water. This material was analyzed.

Analyses. Calc. for  $C_{28}H_{18}O_2$ : C, 85.68; H, 5.17. Found: C, 85.27, 85.35; H, 5.50, 5.56.

Resorcinol and Fluorenone.—Three and one-half g. of fluorenone, 5.4 g. of resorcinol (25% excess) and 9 g. of anhydrous stannic chloride were heated together at 130–140° for 6 hours. The reaction product was treated by a procedure similar to that used in the case of the phenol-fluorenone condensation, except that the steam distillation was omitted. One g. of a brown powder was thereby obtained, and 5.0 g. of the crude material was found to be insoluble in sodium hydroxide solution. This brown powder showed a strong fluorescence in alkaline solution. It was prepared for analysis by treatment with alcohol as already described in the account of the previous experiment.

Analyses. Calc. for C₂₅H₁₈O₄: C, 78.51; H, 4.74. Found: C, 78.12, 78.20; H, 5.10, 5.3.

Bromination of Resorcinol Condensation Products.—One g. of the crystalline resorcinoldiphenein was dissolved in 15 cc. of hot alcohol, the solution placed in an Erlenmeyer flask provided with a reflux water condenser and then 4 g. of bromine (calc. amt.  $\times$  2.7) was added to the boiling solution during the course of an hour. Yellow rhombic crystals soon appeared in the liquid. At the completion of the reaction these were collected and dried. They melted at 273° and weighed 1.2 g. When dissolved in sodium hydroxide solution, the bromine compound gave a yellow solution which showed no fluorescence. If the bromine is added quickly to the hot alcoholic solution or to a cold one, the product is an amorphous powder.

Analyses (crystals dried at 110°). Calc. for  $C_{26}H_{14}O_6Br_4$ : Br, 43.08. Found: 42.90, 42.95.

One g. of the part of the resorcinol-diphenyleneketone-4-carboxylic acid condensation product which was soluble in ammonium hydroxide was brominated in a similar way. Filtration of the cold reaction mixture yielded a brownish-red, amorphous powder which weighed 0.8 g. when washed and dried. It did not melt at 325°, and dissolved in sodium hydroxide solution with the development of a deep red color. This powder was dissolved in a mixture of acetone and alcohol, separated from impurities by filtration and recovered by evaporation of the solvents. Determinations of the bromine content of a sample prepared in this way gave results which were several per cent. below that calculated for the tetrabromo derivative, and which indicated the presence of some dibromo compound or other impurities.

Dyeing Experiments.—A sample of skein silk and one of woolen yarn were worked for half an hour in slightly acid baths containing 3% (based on weight of silk or wool) of the sodium salt of the bromine derivative of the resorcinol-diphenyleneketone-4-carboxylic acid condensation product. The wool was dyed a very light pink, and the silk acquired a flesh color. Parallel experiments in which eosin was used in place of the keto acid derivative gave the usual results.

One gram of woolen yarn previously mordanted with potassium dichromate solution was stirred for an hour in a slightly acid, hot aqueous suspension of 0.4 g. of freshly precipitated and washed pyrogalloldiphenein. After the wool was washed it showed a very slight brown coloration.

# Summary

From the reaction product obtained by condensing phenol with diphenic anhydride in the presence of fuming stannic chloride a crystalline compound, phenoldiphenein, can be obtained. This dissolves in sodium hydroxide solution with development of a yellow color. Crystalline resorcinoldiphenein has been isolated from the crude material secured by heating resorcinol and diphenic anhydride together with the use of fused zinc chloride as a dehydrating agent. Resorcinol-diphenein gives a yellow solution with sodium hydroxide, but does not show fluorescence. The appearance of the solutions of the sodium salts of these compounds is strange in view of the fact that they are similar to phenolphthalein and to fluorescein in structure. The statements made by Dutt and by Bischoff and Adkins as to the constitution and properties of phenoldiphenein and resorcinoldiphenein appear to be in error.

The amorphous condensation product of phenol and diphenyleneke-tone-4-carboxylic acid has been secured by heating these two compounds together and also from the residues left after the removal of the crystal-line compound obtained by the reaction between phenol and diphenic anhydride. The presence of the ketone acid derivative here is apparently due to the transformation of a part of the diphenic anhydride into the isomeric diphenyleneketone-4-carboxylic acid by the action of fuming stannic chloride. This amorphous condensation product dissolves in sodium hydroxide solution with development of a deep red color. Similarly crude resorcinoldiphenein was found to contain the ketone acid-resorcinol product. The latter has also been prepared directly from diphenyleneketone-4-carboxylic acid.

One molecule of fluorenone reacts with two of phenol or of resorcinol to give condensation products which show, respectively, a red color and a green fluorescence in alkaline solutions. Apparently, these compounds, as well as those obtained from diphenyleneketone-4-carboxylic acid, are examples of substances which show indicator effects and fluorescence without the formation of a quinoid ring.

As dyes, the bromine derivatives of resorcinoldiphenein and of the ketone acid-resorcinol condensation product as well as pyrogalloldiphenein have little or no value.

# STUDIES RELATING TO METALLO-ORGANIC COMPOUNDS. III. COMPOUNDS FORMED BETWEEN ALKYL TIN HALIDES AND AMMONIA AND THE AMINES

By Charles A. Kraus and Willard N. Greer Received September 10, 1923

It is known that ammonia, as well as certain of the amines, combines with metallo-organic compounds of the type  $M^nR_{n-1}X$ , where M is a metal of normal valence n, R is a univalent organic group, and X is a strongly electronegative element or group of elements. Compounds of this type have been studied in particular by Werner and Pfeiffer, 1 and the results have been interpreted in terms of Werner's theory. The physical-chemical properties of the different compounds formed by the metallo-organic halides with ammonia and the amines have led us to infer a different constitution. The trimethyl tin group, like other groups of the same type, of the general formula  $M^nR_{n-1}$ , closely resembles hydrogen or the methyl group in its properties. These groups exhibit a marked tendency to add to ammonia or the amines to form compounds of the ammonium type, in which the metallo-organic group is directly attached to nitrogen. The analogy between trimethyl tin iodide and methyl iodide, for example, is complete in this respect. Both add to a tertiary amine, such as pyridine, to form compounds of relatively high melting points, which, in the pure state as well as in solution, exhibit marked electrolytic properties. is to be anticipated that these compounds in the liquid mixture will not be entirely stable; that is, in a mixture of the two components, the meltingpoint curve will exhibit a rounded maximum. While, however, methyl iodide does not add to ammonia or the primary or secondary amines readily under ordinary conditions, trimethyl tin iodide, as well as the other halides of the same group, adds readily to ammonia, the primary and secondary amines, as well as to the tertiary amines, to form compounds of the ammonium type. The group, therefore, resembles hydrogen perhaps somewhat more closely than it does the methyl group.

This behavior on the part of the metallo-organic compounds of this class is not restricted to compounds of tin but probably holds generally, although thus far only tin and mercury compounds have been investigated. It is true, however, that silicon exhibits a similar behavior, triphenyl silicyl chloride combining with one molecule of ammonia to form a compound. Carbon also exhibits this same property. This is shown in a striking manner by those compounds of carbon in which the central carbon atom has approximately the same affinity for the negative electron as have the corresponding metallo-organic groups. Carbon groups of this type are

Werner and Pfeiffer, Z. anorg. Chem., 17, 82 (1898).

found among the compounds of the triphenylmethyl type. Triphenylmethyl chloride, for example, adds a molecule of ammonia to form a comparatively stable compound.

It appeared of interest to investigate the compounds formed in a number of cases. In particular, it appeared of importance to investigate certain of the tin compounds, inasmuch as Werner and Pfeiffer concluded that two molecules of ammonia or an amine were added in the case of these compounds. Thus they found that triethyl tin iodide takes up two molecules of aniline, while the literature indicates that triethyl tin iodide also takes up two molecules of ammonia.

In determining the number of molecules of amine combined with the metallo-organic halide, in general, a determination of the halogen content of the compound was made. These analyses usually checked closely and sufficed to distinguish between one and two molecules of the amine in the compound. In the case of ammonia, however, direct determination of the ammonia was likewise made. In cases where results seemed doubtful, a rough determination of the melting-point curve of mixtures of the constituents was made.

# **Experimental Part**

Trimethyl Tin Chloride and Ammonia.—Trimethyl tin chloride was prepared by treating tetramethyl tin with chlorine in an ice bath with the exclusion of light. The chloride was purified by distillation and finally by recrystallization from petroleum ether at low temperatures.

Trimethyl tin chloride is readily soluble in all types of solvents. The ammonia complex, however, is soluble only in solvents which are capable of dissolving typical salts. The compound does not melt but sublimes at higher temperatures at ordinary pressures.

Trimethyl tin chloride was introduced into a glass tube provided with suitable stopcocks and arranged so that it could be weighed. Ammonia was passed over the compound at ordinary temperatures and pressures after which the ammonia absorbed was determined by weighing, a correction being made for ammonia in the vapor state.

Subs., 0.7384: NH₃ absorbed, 0.0574. Calc. 1 mol. of NH₃, 7.87. Found: 7.77. Trimethyl tin chloride was placed in a tube and ammonia condensed in the same at liquid ammonia temperatures, until all the compound was in solution. The excess of ammonia was then evaporated and finally pumped off for a short time.

Subs., 0.1707, 0.2639: AgCl, 0.1100, 0.1751. Calc. for 1 mol. of ammonia: Cl, 16.40; calc. for 2 mols.: 15.20. Found: 15.94, 16.41.

It is probable that under these conditions the compound takes up two molecules of ammonia, one molecule of which, however, is apparently not firmly held.

A sample of the same material was again placed on the pump and exhausted for two hours, and analyses made as before.

Subs., 0.3426, 0.3823: AgCl, 0.2280, 0.2557. Found: Cl, 16.46, 16.55.

These results show clearly that while trimethyl tin chloride probably takes up two molecules of ammonia, only one molecule is firmly held.

Trimethyl Tin Chloride and Aniline.—Trimethyl tin chloride was dissolved in petroleum ether and aniline added. A solid precipitate was formed which was thrown on the filter, washed with ether and then dried.

Subs., 0.5254, 0.6144: AgCl, 0.2559, 0.3028. Calc. for 1 mol. of aniline: Cl, 12.13. Found: 12.04, 12.19.

The melting-point curve of mixtures of trimethyl tin chloride and aniline was examined. An equimolar mixture solidified homogeneously at 84.5°. With 1.5 mols. of aniline per mol. of chloride initial precipitation took place at 72°. With two mols. of aniline per mol. of chloride the mixture remained liquid at room temperatures.

It is evident that trimethyl tin chloride combines with one molecule of aniline.

Trimethyl Tin Chloride and Pyridine.—Trimethyl tin chloride was treated with pyridine in petroleum ether solution. A white product precipitated at 0° which was washed with petroleum ether and dried; m. p., 37°.

Subs., 0.2522, 0.2668: AgCl, 0.1303, 0.1383. Calc. for 1 mol. of pyridine: Cl, 12.74. Found: 12.78, 12.82.

Trimethyl tin chloride and pyridine combine in equimolar proportions.

Trimethyl Tin Iodide and Ammonia.—A sample of trimethyl tin iodide was dissolved in ammonia, the excess of solvent was evaporated, and the residual vapor removed by connecting to a vacuum pump for a few minutes. The compound was then analyzed for iodine.

Subs., 0.1784, 0.2542: AgI, 0.1326, 0.1910. Calc. for 1 mol. NH₃: I, 41.24; calc. for 2 mols. NH₃: 39.08. Found: 40.18, 40.62.

A sample of the same material was then placed on the pump for a period of one hour, after which it was analyzed.

Subs., 0.3565, 0.5784: AgI, 0.2716, 0.4442. Found: I, 41.18, 41.51.

A sample of the iodide was dissolved in ether and a stream of ammonia gas passed through the solution. The compound precipitated from solution and was washed with ether and dried.

Subs., 0.1867, 0.2076: AgI, 0.1374, 0.1518. Found: I, 39.78, 39.53.

Trimethyl tin iodide evidently combines with two molecules of ammonia, one of which is lost readily, as is indicated by the fact that the sample which was subjected to the action of the pump for only a short period still yielded iodine values intermediate between those for compounds containing one and two molecules of ammonia, respectively. On

the other hand, the iodine content of the compound which was precipitated from ether solution and not subjected to the action of the pump corresponds fairly closely to that of a compound containing two molecules of ammonia.

Trimethyl Tin Iodide and Aniline.—The freezing-point curves of various mixtures of trimethyl tin iodide and aniline were determined. In Table I are given the temperatures at which initial precipitation occurred.

Table I
Freezing-point Data for Mixtures of Trimethyl Tin Iodide and Aniline

Molper cent. aniline	Initial temperature of precipitation °C.	Molper cent. aniline	Initial temperature of precipitation °C.
6.88	52	66.65	95.2
20.11	77	72.22	94.5
34.21	88	76.2	93
50.77	93.5	78.96	92
60.84	95	81.83	90.7

It is evident that trimethyl tin iodide and aniline form a compound containing two molecules of aniline which melts homogeneously at 95.2°. The melting-point curve is extremely flat, which indicates that the compound is comparatively unstable.

Trimethyl Tin Iodide and Pyridine.—An equimolar mixture of trimethyl tin iodide and pyridine was found to melt at 60.5°, the temperature remaining constant until complete solidification had taken place. The further addition of one-half molecular equivalent of pyridine lowered the initial point appreciably, while with the addition of two molecular equivalents of pyridine the initial point of precipitation was lowered to 55°. The mixture was still mushy at room temperatures. Trimethyl tin iodide and pyridine combine in equimolar proportions.

Triethyl Tin Iodide and Pyridine.—Werner and Pfeiffer were unable to obtain a solid precipitate from mixtures of triethyl tin iodide and pyridine. Accordingly, mixtures of these two constituents were subjected to lower temperatures and the course of the melting-point curve approximated. With 40 mol.-per cent. of pyridine the mixture was still soft at —30°. With 50 mol.-per cent. of pyridine the mixture solidified homogeneously at —17°. On further addition of pyridine the melting point was lowered. The mixture containing 66 mol.-per cent. of pyridine still contained liquid at —30°. Trimethyl tin iodide remains liquid at —36°.

Trimethyl tin iodide and pyridine thus form a compound in equimolar proportions which solidifies homogeneously at —17°. This accounts for the failure of Werner and Pfeiffer to establish the formation of a compound.

Dimethyl Tin Dichloride and Pyridine.—The dichloride was dissolved in alcohol and pyridine added, a white precipitate being formed. This

product after washing and drying was found to sublime at a temperature of 145°.

Subs., 0.1321, 0.1578: AgCl, 0.0999, 0.1197. Calc. for 2 mols. of pyridine: Cl, 18.77. Found: 18.71, 18.76.

Evidently one molecule of pyridine is added for each equivalent of chlorine present in the molecule of dimethyl tin dichloride.

Ethyl Mercuric Chloride and Ammonia.—A sample of ethyl mercuric chloride was treated with liquid ammonia in a weighing tube. The excess ammonia was evaporated and the last traces removed by means of a pump.

Subs., 1.4408:  $NH_3$  absorbed, 0.0940. Calc. for 1 mol. of  $NH_3$ :  $NH_3$ , 6.04. Found: 6.12.

Ethyl mercuric chloride and ammonia combine in equimolar proportions. Amyl Mercuric Iodide and Ammonia.—A sample of amyl mercuric iodide was treated with liquid ammonia in a weighing tube and the amount of ammonia absorbed determined by weight after pumping off the excess.

Subs., 0.7282: NH $_3$  absorbed, 0.0288. Calc. for 1 mol. of NH $_3$ : NH $_3$ , 4.10. Found: 3.8.

Amyl mercuric iodide and ammonia combine in equimolar proportions.

When ethyl mercuric chloride and amyl mercuric iodide were treated with triethylamine and with pyridine, compounds were precipitated at 0°. These, however, melted or dissolved when room temperatures were reached and were not investigated further.

#### Discussion

Werner and Pfeiffer attempted to account for the compounds of the trimethyl tin halides with ammonia and the amines on the basis of Werner's theory. They expected to find these compounds combining with two molecules of ammonia or the amines, and indeed they found that in the case of triethyl tin iodide and aniline two molecules of aniline combined with a molecule of the iodide. The results above presented, however, indicate that it is the exception that a trimethyl tin halide combines with two molecules of an amine. Furthermore, in the case of a compound with ammonia, in which instance two molecules are combined with trimethyl tin iodide, one molecule of ammonia is held very loosely while the second molecule is held extremely tenaciously. It is interesting, too, to note that the alkyl mercury halides combine only with a single molecule of ammonia or the amines.

To account for the combination of ammonia and the amines with the alkyl tin halides it appears more rational to assume that the alkyl tin group migrates to the nitrogen atom, yielding pentavalent nitrogen and consequently a compound of the ammonium type. In this case the compound should have the properties of a salt, in view of the known properties of

pentavalent nitrogen in the ammonium group. The reaction is entirely similar to that taking place between methyl iodide, for example, and pyridine, in which case reaction takes place according to the following equation:  $CH_3I + C_6H_5N = C_6H_5NCH_3I$ . In the case of trimethyl tin iodide, reaction takes place according to the equation:  $(CH_3)_3SnI + C_6H_5N = C_6H_5NSn(CH_3)_3I$ .

This view of the constitution of the compounds formed between the alkyl metal halides and ammonia and its derivatives is in agreement with the properties of the resulting compounds; more particularly, it serves to account for the fact that solutions of the alkyl metal halides in the amines conduct the current with considerable facility, while solutions of the same substances in solvents of the non-basic type are virtually non-conductors.

The alkyl metal groups, such as the trimethyl tin group, have a very marked affinity both for nitrogen and for oxygen. As will be shown in a later paper, these groups are not only able to combine with nitrogen to form compounds of the ammonium type, but under suitable conditions they also combine with oxygen to form stable compounds of the oxonium type.

# Summary

The compounds of the alkyl tin and the alkyl mercury halides with ammonia and the amines have been investigated. It has been shown that trimethyl tin chloride and iodide combine with two molecules of ammonia, only one of which is firmly held. Trimethyl tin chloride combines with one molecule of aniline and pyridine, respectively. Trimethyl tin iodide combines with one molecule of pyridine. In the case of aniline, trimethyl tin iodide forms a compound containing two molecules of the former. Dimethyl tin chloride combines with two molecules of ammonia. Ethyl mercuric chloride and amyl mercuric iodide combine each with one molecule of ammonia.

It is pointed out that the results do not agree well with Werner's theory, as outlined by Werner and Pfeiffer. It is suggested that the properties of the resulting compounds are more rationally accounted for on the assumption that the alkyl metal group is transferred from the halogen atom to the nitrogen atom of the amine, thus forming a compound of the ammonium type.

# THE ADDITION OF NITROGEN TRICHLORIDE TO UNSATURATED HYDROCARBONS. I

By G. H. Coleman and H. P. Howells Received September 11, 1923

In a recent study¹ of the chlorinating action of nitrogen trichloride on benzene and toluene, it was found that small amounts of chloro-amines were formed, presumably by the addition of nitrogen trichloride to the aromatic nucleus. The products obtained in each case proved to be mixtures of chlorinated amines which could not easily be separated.

The present investigation was undertaken to determine whether such an addition might not occur with hydrocarbons of the ethylene series with the formation of a single product. The hydrocarbons used were 2-butene, 1-butene, and trimethylethylene. The reactions were carried out in carbon tetrachloride solution, well cooled with a freezing mixture.

With 2-butene the reaction takes place fairly rapidly with the formation of a moderate yield of 2-chloro-3-dichloro-amino-butane, CH₃CHNCl₂-CHClCH₃, considerable free nitrogen, and a small amount of ammonium chloride. The above chloro-amine was not isolated as such, but by treatment with concd. hydrochloric acid was reduced to the corresponding 2-chloro-3-amino-butane, CH₃CHNH₂CHClCH₃. A possible explanation of this action of hydrochloric acid has been given by Coleman and Noyes.¹ A similar action of hydrogen chloride on a chloro-amine in ether solution is mentioned by Berg.²

With 1-butene the reaction occurs more slowly and a larger excess of the unsaturated hydrocarbon is required. The yield of amine is slightly less than with 2-butene. The amounts of free nitrogen and ammonium chloride are about the same. In this reaction there are, of course, two possible structures for the addition product, CH₃CH₂CHNCl₂CH₂Cl and CH₃CH₂-CHClCH₂NCl₂. On the basis of Markownikoff's rule³ for such addition reactions the position taken by the dichloro-amino group might have a bearing on the polarity of the chlorine in nitrogen trichloride. If it is assumed that the chlorine is positive, then according to this rule the dichloro-amino group should be attached to the second carbon atom from the end. This was shown to be the case by reduction of the product to 2-amino-butane. No evidence of the formation of the other possible isomer was obtained.

Racemic sec-butyl amine (2-amino-butane) has been prepared by

¹ Coleman and Noyes, This Journal, 43, 2213 (1921).

<sup>Berg, Chem. Zentr., [3] 7, 542 (1892).
Markownikoff, Ann., 153, 256 (1870).</sup> 

Pope and Gibson⁴ by the reduction of methylethyl ketoxime. In order to compare this compound with our product the work of these authors was repeated. The melting point of the benzoyl derivative was found to be several degrees higher than that recorded (see Experimental Part), but it agreed exactly with that of our product obtained through the reduction of the chloro-amine. A mixture of these substances melted at the same temperature. The *p*-nitrobenzoyl derivatives prepared by the two series of reactions were also found to be identical.

If in the addition of nitrogen trichloride to 1-butene the dichloro-amino group had added to the end carbon atom, then by reduction n-butylamine would be formed. The derivatives of n-butylamine do not correspond in physical properties to the same derivatives of the amine obtained in this investigation.

The reaction with trimethylethylene differs from those described above in that it is more rapid, a greater proportion of ammonium chloride is formed, and no amine is obtained from the reaction mixture. In fact, all but a trace of the nitrogen used can be accounted for as ammonium chloride and free nitrogen.

The formation of ammonium chloride in these reactions, and particularly in the last one where the proportion of this compound is considerably greater, is no doubt due to the reaction of nitrogen trichloride with hydrochloric acid, which may split out from the addition product first formed with the unsaturated hydrocarbon. Noyes⁵ has shown that nitrogen trichloride and hydrochloric acid yield ammonium chloride and chlorine quantitatively even in the absence of water.

The complete decomposition of the addition product which is probably first formed with trimethylethylene may be connected with the presence of a tertiary carbon atom in this compound and the fact that the nitrogen is very likely attached to this atom. Marvel⁶ has recently shown that in dialkyl mercury compounds the carbon-mercury linkage is much more easily broken when mercury is attached to a tertiary alkyl group than when it is attached to a secondary or a primary alkyl group. These facts are in agreement with what is already known concerning alcohols, halides and other compounds. By the action of chlorine on trimethylethylene Hell⁷ obtained monochloro-amylene,  $C_5H_9Cl_3$  amylene dichloride,  $C_5H_1oCl_2$ ; and chloro-amylene chloride,  $C_5H_9Cl_3$ . He concludes that a part of the amylene dichloride first formed must split out hydrochloric acid. The resulting unsaturated monochloro-amylene would then in part react with more chlorine. In the present work both the dichloro and the trichloro com-

⁵ Noves. This Journal, 42, 2173 (1920).

Marvel, ibid., 45, 820 (1923).

⁷ Hell, Ber., 24, 217 (1891).

pounds were found, but the presence of monochloro-amylene was not definitely proved.

The investigation is being continued in this Laboratory with other unsaturated compounds and also with reference to a possible increase in the yields obtained.

# **Experimental Part**

#### The Reaction with 2-Butene

The preparation and analysis of nitrogen trichloride was carried out as described by Coleman and Noyes, with some slight modifications. Carbon tetrachloride was used as the solvent for the trichloride. The temperature of the cooling bath was maintained at 0– $10^{\circ}$ ; N ammonium nitrate solution was used as the source of the ammonia. After the addition of the chlorine the aqueous solution was removed and the carbon tetrachloride stirred for a short time with a little fresh ammonium nitrate solution. This was repeated a second time to insure the removal of any excess chlorine. Solutions containing as much as 20% of nitrogen trichloride were prepared but, in general, it was found best to use more dilute solutions.

The 2-butene was prepared from sec-butyl iodide and alcoholic potassium hydroxide, according to the method described by de Luynes.8 After it was washed and dried, the gas was passed into dry carbon tetrachloride, surrounded by a cooling bath. The reaction was carried out by adding the nitrogen trichloride solution through a dropping funnel, slowly, to the solution of the unsaturated compound contained in a flask surrounded by a freezing mixture of ice and salt (-10°). The apparatus was so arranged that the solution could be agitated during the addition, and any gas evolved could be collected and measured. When the yellow color of the nitrogen trichloride had completely disappeared, the solution was washed several times with water to remove any ammonium chloride. After it had been carefully separated from the water it was thoroughly shaken with 30-40 cc. of concd. hydrochloric acid. It was found desirable to have enough excess butene present to unite with the chlorine liberated at this point, in the reaction between the acid and the chloro-amine. If necessary, more of the butene solution was added. The hydrochloric acid was diluted with water and separated from the carbon tetrachloride. This acid solution now contained the hydrochloride of 2-chloro-3-amino-butane.

The reduction of the chloro-amine can also be effected by shaking it with an acid sulfite solution, but the reaction is not as complete as with concd. hydrochloric acid. It is interesting to note here that while these aliphatic chloro-amines can be quite easily reduced with an acid sulfite, the chloro-amines obtained by Coleman and Noyes¹ from benzene and toluene were reduced with difficulty, or not at all, by this reagent.

⁸ De Luynes, Ann., 132, 275 (1864).

The amounts used in a typical run were as follows.

One hundred and fifty-six mg. mols. of nitrogen trichloride in 400 g. of carbon tetrachloride; 220 mg. mols of 2-butene (determined by titration with bromine) in 400 g. of carbon tetrachloride. In this run there was formed 11 mg. mols. of ammonium chloride and 45.5 mg. mols. of the amine (isolated as the benzoyl derivative). The remainder of the nitrogen was given off as a gas during the reaction.

r-Benzoyl-2-chloro-3-amino-butane.—The benzoyl derivative of the amine was prepared from the solution of the hydrochloride above, by the usual Schotten-Baumann method; 9.6 g. was obtained, which is 29% calculated from the nitrogen trichloride. This was recrystallized several times from petroleum ether (b. p., 100–110°). Colorless needle-like crystals were formed, melting at 105–106° (uncorr.). The substance was analyzed for nitrogen by the Gunning-Arnold-Dyer modification of Kjeldahl's method, and for chlorine by the sodium peroxide bomb method described by Lemp and Broderson.

Analyses. Subs., 0.1526, 0.2237: 7.25, 10.8 ec. of 0.1 N HCl. Calc. for  $C_{11}H_{14}$ -ONCl: N, 6.63. Found: 6.65, 6.76.

Subs., 0.1726, 0.1523: 8.18, 7.21 cc. of 0.1 N AgNO₃. Calc. for  $C_{11}H_{14}ONCI$ : Cl, 16.80. Found: 16.83, 16.80.

### . The Reaction with 1-Butene

1-Butene was prepared from *n*-butyl iodide and alcoholic potassium hydroxide according to the method of Grabowsky and Saytzeff.¹⁰ The apparatus used and the method of carrying out the reaction were the same as given above, for 2-butene. In this case, however, a larger excess of the unsaturated compound was necessary, and a longer time was required for the color of the nitrogen trichloride to disappear. The carbon tetrachloride solution was shaken with water to remove ammonium chloride, then with concd. hydrochloric acid as before. The amounts used in a typical run were the following: 150 mg. mols. of nitrogen trichloride in 400 g. of carbon tetrachloride, 260 mg. mols. of 1-butene in 400 g. of carbon tetrachloride; 11.3 mg. mols. of ammonium chloride was formed, 35.5 mg. mols. of amine, and the remainder of the nitrogen was liberated as a gas.

r-Benzoyl-1-chloro-2-amino-butane.—One-third of the hydrochloric acid solution was used for the preparation of the benzoyl derivative by the Schotten-Baumann method;  $2.5 \, \mathrm{g}$ . of substance was obtained, which is a yield of 23.6%. The product was recrystallized several times from petroleum ether (b. p.,  $100-110^{\circ}$ ). Fine, silky needles in small clusters were formed, melting at  $91-92^{\circ}$  (uncorr.). Careful working up of the mother liquors failed to indicate the presence of more than one compound.

Analyses. Subs., 0.1520, 0.1744: 7.25, 8.36 cc. of 0.1 N HCl. Calc. for  $C_{11}H_{14}$ -ONCl: N, 6.63. Found: 6.68, 6.71.

Subs., 0.1670, 0.1504: 7.96, 7.15 cc. of 0.1 N AgNO₃. Calc. for  $C_{11}H_{14}ONCl$ : Cl, 16.80. Found: 16.90, 16.87.

r-Benzoyl-2-amino-butane.—The remaining two-thirds of the hydrochloric acid solution described above was cooled and nearly neutralized with sodium hydroxide. An excess of 2.5% sodium amalgam was then slowly added. The solution was stirred with a mechanical stirrer, and kept slightly acid to litmus by the addition of concd. hy-

Lemp and Broderson, This Journal, 39, 2069 (1917).

¹⁰ Grabowsky and Saytzeff, Ann., 179, 330 (1875).

drochloric acid as required. The amalgam was made by the modification of Nef's method, described by Raiford and Clark. After separating the solution from the mercury, one-half was used for the preparation of the benzoyl derivative; 1.5 g. was obtained, which after recrystallizing from petroleum ether (b. p., 100–110°), formed colorless needles, melting at 84–85° (uncorr.). The substance was found to contain no chlorine.

Analyses. Subs., 0.2302, 0.0945: 12.9, 5.36 cc. of 0.1 N HCl. Calc. for  $C_{11}H_{15}$ -ON: N, 7.92. Found: 7.84, 7.94.

In order to characterize the compound further the other half of the solution described above was used for the preparation of the p-nitrobenzoyl derivative. After recrystallizing several times from petroleum ether (b. p., 120–150°), the substance melted at 114.5–115.5° (uncorr.). As mentioned above, Pope and Gibson⁴ prepared racemic sec-butylamine (2-amino-butane) by the reduction of methylethyl ketoxime with sodium amalgam. The melting point of the benzoyl derivative recrystallized from aqueous alcohol is recorded as 75–76°. This compound was prepared as described by these authors and after recrystallizing several times from petroleum ether (b. p., 100–110°), melted at 84–85° (uncorr.). A mixture of this compound with r-benzoyl-2-amino-butane, obtained through the reduction of the chloro-amine, melted at the same temperature.

The p-nitrobenzoyl derivative was also prepared from the amine obtained by the reduction of the ketoxime. After recrystallizing from petroleum ether (b. p., 120–150°) this product melted at 114.5–115.5° (uncorr.). When mixed with r-(p-nitrobenzoyl)-2-amino-butane obtained through the reduction of the chloro-amine no change in melting point was observed.

p-Nitrobenzoyl-n-butylamine.—If, as stated above, in the addition of nitrogen trichloride to 1-butene the dichloro-amino group had added to the end carbon atom to form CH₃CH₂CHClCHNCl₂, then by reduction n-butylamine would be formed. The benzoyl derivative of n-butylamine was prepared. This was a clear oil, soluble in hot petroleum ether, and was not obtained in crystalline form. The p-nitrobenzoyl derivative was prepared, and after recrystallizing from petroleum ether (b. p., 120–150°) melted at 102.5–103° (uncorr.).

# The Reaction with Trimethylethylene

Nitrogen trichloride reacted very rapidly with trimethylethylene. During the addition of the trichloride solution, the yellow color disappeared very quickly as long as there was an excess of the unsaturated compound present, nitrogen gas was given off and a heavy white precipitate of ammonium chloride was formed. The ammonium chloride was filtered off, and the carbon tetrachloride tested for the presence of an amine. None was found. The white precipitate was washed with carbon tetrachloride and dried. Analysis for chlorine showed it to be ammonium chloride.

Analysis. Subs., 0.2102: AgCl, 0.5648. Calc. for NH₄Cl; Cl, 66.33. Found: 66.49.

The following table gives the amounts of the materials used and the products formed in three typical runs. The nitrogen trichloride was in each case dissolved in about 320 g. of carbon tetrachloride and the trimethylethylene in about 240 g. of carbon tetrachloride.

¹¹ Raiford and Clark, This Journal, 45, 1738 (1923).

Table I
Nitrogen Trichloride with Trimethylethylene

	I	II	III	
	,	—Mg. mols.——		
$C_5H_{10}$	100	100	100	
$NCl_3$	50.4	55.3	57.7	
NH ₄ Cl	14.5	15.5	16.1	
$N_2$ , mg. atoms	35.6	39.2	37.7	

Careful fractionation of the carbon tetrachloride solutions from the three runs yielded two very definite fractions with boiling points above that of carbon tetrachloride, one at 130–133° and the other at 174–180°. There was little or no indication of a fraction corresponding to monochloro-amylene. According to Hell⁷ monochloro-amylene,  $C_5H_9Cl_3$ , amylene dichloride,  $C_5H_10Cl_2$ , and chloro-amylene chloride,  $C_5H_9Cl_3$ , boil at 92–93°, 130–133°, and 174–180°, respectively.

Chlorine determinations were made by Carius' method on the two fractions mentioned.

Analyses. Fraction 130-133°. Subs., 0.1662: AgCl, 0.3335. Calc. for C₅H₁₀Cl₂: Cl, 50.35. Found: 49.93.

Fraction 174–180°. Subs., 0.2098: AgCl, 0.5127. Calc. for  $C_5H_9Cl_5$ : Cl, 60.45. Found: 60.66.

# Summary

- 1. Nitrogen trichloride adds to 2-butene to form 2-chloro-3-dichloro-amino-butane. This amine is reduced by concd. hydrochloric acid to 2-chloro-3-amino-butane.
- 2. Nitrogen trichloride adds to 1-butene to form 1-chloro-2-dichloro-amino-butane. The structure of this product was proved by reduction to 2-amino-butane (sec-butylamine).
- 3. According to Markownikoff's rule, the addition of nitrogen trichloride to 1-butene to form 1-chloro-2-dichloro-amino-butane, agrees with the assumption that the chlorine in nitrogen trichloride is positive.
- 4. Nitrogen trichloride reacts rapidly with trimethylethylene to form ammonium chloride, nitrogen, and amylene chlorides.

# THE CATALYTIC CONDENSATION OF ACETYLENE WITH BENZENE AND ITS HOMOLOGS

By Joseph S. Reichert and J. A. Nieuwland Received September 20, 1923

# The Preparation of Diphenylethane

Unsymmetrical diphenylethane has been prepared¹ by the condensation of benzene with paraldehyde in the presence of concd. sulfuric acid. It has been demonstrated that acetylene may be substituted for acetaldehyde in the preparation of quinaldine² and the acetals.³ The method described in this paper consists in the similar substitution of acetylene for acetaldehyde in the preparation of diphenylethane from benzene and paraldehyde according to Baeyer. This synthesis may in a general way be represented by the equation,  $C_2H_2 + 2C_6H_6 \longrightarrow CH_3CH(C_6H_5)_2$ . Acetylene does not combine with benzene directly as indicated in this equation. However, when acetylene is passed into a mixture of benzene and concd. sulfuric acid in the presence of a mercury salt as a catalyst, the condensation of acetylene and benzene into diphenylethane is readily effected.

Experimental Part.—A mixture of 500 cc. of benzene, 50 cc. of concd. sulfuric acid and 5 g. of mercuric sulfate was put into a flask fitted with a 2-hole stopper, one hole of which was closed with a glass rod, the other fitted with a glass tube bent at a right angle. The flask was then tared and connected with a gasometer containing acetylene under a pressure of about 1.5 meters of water. The acetylene was washed through coned. sulfuric acid. The system was swept free from air by removing the glass rod from the stopper. The absorption of acetylene took place quite rapidly with the evolution of considerable heat. The flask was cooled by immersion in ice water. The absorption was continued until approximately three-fourths to four-fifths of the calculated amount of acetylene had been absorbed. During the absorption the reaction mixture turned first yellow and then brown. With the proper cooling there was little evidence of the formation of tarry or solid products. The absorption was completed in from two and one-half to three hours. To isolate the products, the reaction mixture was diluted with four times its volume of water and neutralized with sodium carbonate. The emulsion which formed upon the addition of sodium carbonate was broken by heat and the addition of common salt, or by extraction with ether. The two layers were then separated. and the upper layer which contained the hydrocarbons was subjected to a fractional distillation. Between 75° and 105° some unchanged benzene distilled. The temperature rose rapidly to 250° when diphenylethane commenced to distil. There was no evidence of decomposition until the temperature reached about 340°. By repeated fractionation diphenylethane was obtained; b. p., 268-272°. From the higher-boiling fraction a small amount of dimethylanthracene hydride was obtained. This product is formed by the condensation of two molecules of acetylene with two molecules of benzene. A yield of 40 to 50% of the calculated amount of diphenylethane referred to the amount of acetylene absorbed was obtained. The best yields were obtained when the reaction

¹ Baeyer, Ber., 7, 190 (1874).

² Nieuwland and Vogt, This Journal, 43, 2671 (1921).

³ Reichert, Bailey and Nieuwland, ibid., 45, 1552 (1923).

was allowed to take place at 10° to 20°. When the reaction took place without being cooled, the heat of reaction raised the temperature of the mixture up to 60° or 70°. Under these conditions the acetylene was absorbed even more rapidly but the yield of diphenylethane was thereby greatly reduced and instead of diphenylethane, products of a solid character were obtained. When the reaction was allowed to take place at higher temperatures there was evidence of the formation of sulfur dioxide also. It was thought possible that under the influence of the reduced mercury which is formed in small quantities in the reaction, the sulfuric acid might have oxidized the diphenylethane to benzophenone or the dimethylanthracene hydride to anthraquinone. These substances were, however, not found among the products of the reaction.

# The Preparation of the Homologs of Diphenylethane

Baeyer's method for the preparation of diphenylethane was applied by Fischer⁴ to the preparation of ditolylethane, namely, the condensation of toluene with paraldehyde in the presence of sulfuric acid. The process described in this paper consists in the substitution of acetylene for acetaldehyde in Fischer's method for the preparation of ditolylethane. Anschütz,⁵ who prepared diphenylethane and ditolylethane by the action of ethylidene chloride on benzene and toluene, respectively, likewise prepared dixylylethane by the same method. No reference was found in the literature to the preparation of dimesitylethane or ethylidene bis-ethylbenzene.

The method just described for the preparation of diphenylethane was found applicable to the preparation of its homologs. With toluene a 45 to 50% yield of ditolylethane (b. p., 295–300°), together with a small yield of tetramethylanthracene hydride was obtained. Xylene yielded 50 to 55% of dixylylethane (b. p., 322–326°) and a small amount of a high-boiling fraction, probably hexamethylanthracene hydride. Mesitylene, prepared by the condensation of acetone according to Bender and Erdmann, yielded 18 to 20% of dimesitylethane; b. p., 344–348°. The absence of a high-boiling fraction in this case coincides with the fact that the condensation of two molecules of acetylene with two molecules of mesitylene to form octamethylanthracene hydride is theoretically impossible. Ethyl benzene, prepared from ethyl bromide and bromobenzene according to Gattermann, yielded 20 to 25% of ethylidene bis-ethylbenzene, and a small amount of a high-boiling fraction, probably dimethyldiethylanthracene hydride. Both dimesitylethane and ethylidene bis-ethylbenzene are fluorescent and like their homologs boil without decomposition.

# Summary

A new and practical method for the preparation of diphenylethane, ditolylethane and dixylylethane is described. This method consists in the condensation of acetylene with benzene, toluene and xylene, respectively, in the presence of concd. sulfuric acid and a mercury salt.

This method has been applied to the preparation of the two compounds, dimesitylethane and ethylidene bis-ethylbenzene.

# THE ACTION OF HYDROXYLAMINE AND OF HYDRAZINE ON THE ARYL MONOTHIO AMIDES OF CARBETHOXY-ETHYLMALONATE

By DAVID E. WORRALL

RECEIVED SEPTEMBER 29, 1923

The addition products obtained by the action of phenyl mustard oil and para substituted mustard oils on ethyl aceto-acetate were shown in a previous communication¹ to be useful for the preparation of heterocyclic compounds of the isoxazole and pyrazole series. The reagents used were hydroxylamine and hydrazine. Similar series of reactions have been found to take place with the corresponding mustard oil addition products of malonic ester.

Thus, carbethoxy-ethylmalonate monothio-anilide, formed by the action of phenyl mustard oil on diethylmalonate reacts with hydroxylamine as follows:  $CS(NHC_6H_5)CH(COOC_2H_5)COOC_2H_5 + NH_2OH = H_2S + C(NHC_6H_5)CH(COOC_2H_5)CO + C_2H_5OH$ .

The actual product obtained is the hydroxylamine salt of the above compound; consequently, it is necessary to use two equivalents of the base. The free isoxazole is obtained by decomposition of the salt with hydrochloric acid. It is less basic than the corresponding isoxazole obtained from aceto-acetic ester and does not form a salt with acids. It is insoluble even in warm coned. hydrochloric acid. It readily dissolves in dil. sodium hydroxide solution, changing to a sodium salt.

Hydrazine reacts with carbethoxy-ethylmalonate monothio-anilide to form a pyrazole:  $CS(NHC_6H_5)CH(COOC_2H_5)COOC_2H_5 + NH_2NH_2 = H_2S + C(NHC_6H_5)CH(COOC_2H_5)CO + C_2H_5OH.$ 

N-----NH

The pyrazole is soluble in warm concd. hydrochloric acid solution and is also soluble in sodium hydroxide solution from which the sodium salt may be isolated.

The series of reactions starting with malonic ester and resulting ultimately in isoxazoles and pyrazoles is somewhat less restricted in scope than the series beginning with ethyl aceto-acetate. This is due to the fact that the addition products of *ortho* and *meta* substituted mustard oils to ethyl aceto-acetate undergo hydrolysis so readily to the thio amides of acetic acid that ring formation is not possible.\(^1\) No such difficulty presents itself in the malonic ester series.

¹ Worrall, This Journal, 44, 1551 (1922).

# Experimental Part

carbethoxy-ethylmalonate monothio-anilide were added 2 equivalents of free hydroxylamine dissolved in approximately 80 cc. of alcohol and prepared by neutralization of the hydrochloride with potassium hydrogen carbonate. The mixture was heated under a reflux condenser for 6 hours and then poured into a beaker where it rapidly solidified to a sticky cake. This product was dried on a porous plate, stirred with 50 cc. of warm water with which it formed a thick paste, and 10 cc. of dil. hydrochloric acid was added. A gum formed as a result of the action of the acid, but it quickly changed to a compact crystalline substance, easy to manipulate; yield, 6.5 g. Finally, the isoxazole was further purified by two crystallizations from an alcohol.

Analyses. Calc. for C₁₂H₁₂O₄N₂: C, 58.1; H, 4.8. Found: C, 58.4; H, 4.6.

It is readily soluble in hot alcohol from which it separates in small, stout needles softening at 160° and melting at 166° with foaming, due to the evolution of carbon dioxide, accompanied by decomposition.

Permanganate solution is decolorized in the cold by the isoxazole, resulting in the formation of phenyl isonitrile. It reacts with bromine in glacial acetic acid solution to form a crystalline derivative, but it is changed to a tar by concd. nitric acid. It is insoluble in concd. hydrochloric acid even when warmed and sparingly soluble in hot water. Warm sodium hydroxide solution easily dissolves the substance, forming a sodium salt that separates in the form of slender needles as the solution cools. A mustard-colored copper salt is precipitated from hot water solution by copper acetate.

3-Anilino-4-carbethoxy-5-oxy-pyrazole, COOC₂H₅.HC—CNHC₆H₅.—Two equiv-

alents of free hydrazine, prepared from the sulfate by neutralization with potassium hydrogen carbonate, dissolved in 80 cc. of alcohol were added to 10 g. of carbethoxyethylmalonate monothio-anilide. The mixture was heated under a reflux condenser for 4 to 5 hours. A dark green color developed at first but subsequently disappeared. The bulky crystalline product that formed on standing was filtered with suction, washed with a few cubic centimeters of cold water and mixed with approximately 50 cc. of water containing 10 cc. of dil. hydrochloric acid. No apparent change took place. The product was filtered by suction and recrystallized from 100 cc. of alcohol; yield, approximately 5 g.

Analyses. Calc. for C12H13O3N3: C, 58.3; H, 5.3. Found: C, 58.2; H, 5.2.

The pyrazole is sparingly soluble in hot water and somewhat more soluble in hot alcohol. A voluminous precipitate of fluffy white needles separated as the solution cooled. It softened at 187°, partially melting with decomposition at 194–195°. It decolorized both permanganate solution and bromine dissolved in carbon tetrachloride, and was violently acted upon by concd. nitric acid to form a black tar. A sodium salt, lustrous white leaves rapidly hydrolyzed by hot water, formed when the material was warmed with sodium hydroxide solution.

3-o-Toluidino-4-carbethoxy-5-isoxazole, COOC₂H₅.C₃H₂ON.NHC₆H₄CH₃.—A mixture of 10 g. of crude² carbethoxy-ethylmalonate monothio-o-toluide with two equivalents of hydroxylamine in alcohol solution was heated for 6 hours under a reflux condensity.

² The thio compound obtained by the action of o-tolyl mustard oil on malonic ester did not crystallize on standing; hence it had to be used without purification.

ser. The product which separated on cooling was filtered with suction, decomposed with hydrochloric acid and twice crystallized from alcohol; yield of purified substance, approximately 2 g.

Analyses. Calc. for C12H14O4N2: C, 59.5; H, 5.3. Found: C, 59.2; H, 5.1. -

The isoxazole crystallizes from alcohol in flat needles and plates melting with decomposition at  $165-167^{\circ}$  with preliminary softening.

3-o-Toluidino-4-carbethoxy-5-oxy-pyrazole, COOC₂H₅.C₂H₂ON₂.NHC₆H₄CH₃.—A mixture of 10 g. of crude carbethoxy-ethylmalonate monothio-o-toluide with an alcoholic solution of two equivalents of hydrazine was heated until no further evolution of hydrogen sulfide took place. The precipitate which formed on cooling was treated with hydrochloric acid to free it from hydroxylamine, filtered off and twice crystallized from alcohol; yield, approximately 2 g.

Analyses. Calc. for  $C_{13}H_{15}O_{2}N_{3}$ : C, 59.8; H, 5.7. Found: C, 59.4; H, 5.5.

The pyrazole separates from alcohol in flocks of feathery, white needles. It softens at 205°, partially melting with decomposition at 215°.

3-p-Toluidino-4-carbethoxy-5-oxy-isoxazole,  $COOC_2H_5$ . $C_3H_2O_2N$ .CHNC $_6H_4CH_3$ .—A mixture of 10 g, of carbethoxy-ethylmalonate monothio-p-toluide with two equivalents of hydroxylamine in alcoholic solution was heated under a reflux condenser for 5 hours. Then 4 cc. of concd. hydrochloric acid was added directly to the hot alcoholic solution. Since the resulting precipitate contained considerable inorganic material it was twice digested with 25 cc. of warm water, cooled and filtered with suction; yield, 5.2 g. The product was finally crystallized from alcohol.

Analyses. Calc. for C₁₃H₁₄O₄N₂: C, 59.5; H, 5.3. Found: 59.7; H, 5.3.

The p-toluidino-isoxazole separates from alcohol in needles and plates melting with decomposition at 172–173°.

3-p-Toluidino-4-carbethoxy-5-oxy-pyrazole, COOC₂H₅.C₃H₂ON₂.NHC₆H₄CH₅.—A mixture of 10 g. of carbethoxy-ethylmalonate monothio-p-toluide with two equivalents of hydrazine in alcoholic solution was heated under a reflux condenser for four hours; 5 cc. of concd. hydrochloric acid was added to the mixture while it was still warm. The product was thoroughly washed with water and then was crystallized from alcohol; yield of purified substance, 4 g.

Analyses. Calc. for C13H15O3N3: C, 59.8; H, 5.7. Found: C, 60.0; H, 5.7.

The pyrazole separates from alcohol as a bulky precipitate of feathery needles. When heated above 200° it undergoes slow decomposition without melting.

3-p-Bromo-anilino-4-carbethoxy-5-oxy-isoxazole, COOC₂H₅.C₃HO₂N.NHC₆H₄Br.— Five g. of carbethoxy-ethylmalonate monothio-p-bromo-anilide was treated in the customary manner with hydroxylamine, the product decomposed with acid and purified by crystallization from alcohol; yield of purified compound, 2.4 g.

Analysis. Calc. for C₁₂H₁₁O₄N₂Br: Br, 24.5. Found: 24.1.

The bromo-anilino-isoxazole separates from alcohol in slender needles which slowly sinter together and melt with decomposition at 163-170°.

3-p-Bromo-anilino-4-carbethoxy-5-oxy-pyrazole,  $COOC_2H_5$ . $C_3H_2ON_2$ . $NHC_6H_4Br$ .— Five g. of carbethoxy-ethylmalonate monothio-p-bromo-anilide was heated in alcohol solution with two equivalents of hydrazine, the product treated with acid and recrystallized from alcohol.

Analysis. Calc. for C12H12O3N3Br: Br, 24.5. Found: 24.2.

The new pyrazole separates from alcohol in small fluffy needles, which soften at  $212\,^\circ$  and melted at  $217\,^\circ$ .

# Summary

The addition products obtained by the action of phenyl, o-tolyl and p-bromo mustard oils on diethylmalonate condense with hydroxylamine and hydrazine to form, respectively, isoxazoles and pyrazoles.

MEDFORD HILLSIDE, MASSACHUSETTS

# THE KETENIC DECOMPOSITION OF KETONES. KETENE AND METHYL KETENE

By Charles DeWitt Hurd Received October 3, 1923

Undoubtedly, the best way to prepare ketene is to decompose acetone vapors at high temperatures. Recently, it has been demonstrated that ketene may be prepared in a similar manner, but with poorer yields, from methylethyl ketone. It was considered probable that methyl ketene would also be formed in this reaction, but there seemed to be no positive evidence for such an occurrence.¹

Ketene was identified as acetanilide, its reaction product with aniline. Methyl ketene would have formed propionanilide. This was not isolated, but there was found an unidentified crystalline product that melted at 80°, about 25° lower than the melting point of propionanilide. A similar low-melting toluidine reaction product was observed. One purpose of the present investigation was to establish the identity of these substances.

A second problem with which this paper deals was to ascertain whether or not methyl ketene was decomposed by heat. An opinion was expressed by Hurd and Kocour² that methyl ketene may actually have been prepared in their experiment, but that it may have decomposed at the temperature to which it was exposed. In order to answer this question, it was approached from two angles. First, an apparatus was built which heated the ketone vapors for a briefer period of time than formerly. The heating unit of this consisted of an electrically heated platinum filament, described below. If methyl ketene is susceptible to heat, an apparatus of this type should result in an augmented yield of methyl ketene. It seems probable that a short combustion furnace instead of the long one employed formerly, might also produce an increased yield of methyl ketene. This idea has not been tried experimentally as yet, however.

In the second place, a study was made of the ketenic decomposition of diethyl ketone. Because of its symmetrical structure, this ketone should

¹ (a) Hurd and Kocour, This Journal, 45, 2167 (1923). For the preparation of ketene from acetone, see (b) Hurd and Cochran, *ibid.*, 45, 515 (1923); also, a footnote to the article by Hurd and Kocour.

² Ref. la, p. 2168.

give as a primary decomposition product, methyl ketene:  $CH_3$ — $CH_2$ —CO— $C_2H_5$   $\longrightarrow$   $CH_3$ —CH=CO +  $C_2H_6$ . There is no chance for other ketenes to be formed, except as decomposition products of the methyl ketene. Therefore, it bears upon the question to study this reaction and to study the fate of the methyl ketene.

The general results may be conveniently classified under three headings: (1) comparison of results due to the change of apparatus; (2) the identity of the low-melting aniline (or toluidine) reaction product, noted in the paper of Hurd and Kocour; and (3) the behavior of diethyl ketone towards heat.

1. Acetone vapors give a better yield of ketene with the former apparatus, namely, the long combustion furnace. Methylethyl ketone, on the contrary, gave with the present platinum wire apparatus both a better yield of ketene, identified as acetanilide, and also a larger quantity of the 80° material. No work was done with diethyl ketone in the former type of apparatus. This substance was decomposed by the hot platinum wire filament, however, to produce both ketene and methyl ketene in comparatively high yields. This is discussed in more detail below.

Diethyl ketone formed a considerable quantity of higher-boiling condensation products, and very little of the original ketone could be recovered in the distillate. In this respect, it differed from acetone and methylethyl ketone. With diethyl ketone, also, a larger carbon deposit was formed in the apparatus.

- 2. The 80° material was shown to be a mixture of acetanilide and propionanilide. This was indicated by its appearance and by its solubility characteristics. It was conclusively demonstrated by tests and by analysis. A mixture with identical properties was prepared from pure acetanilide and pure propionanilide. To form it, merely recrystallization of these 2 anilides from appropriate solvents was necessary. Similarly, the low-melting substance formed when toluidine was used in the place of aniline was found to be a mixture of aceto- and propiono-toluidides. Both of these mixtures appeared homogeneous, both melted completely within 0.5°, and both solidified rapidly when cooled a few degrees below the melting point. Several recrystallizations from various solvents did not change the melting point. Therefore, it was erroneously thought for a time that the substances might be pure chemical individuals. That they are mixtures, however, is now settled definitely.
- 3. It will be recalled that methyl ketene alone was anticipated in the decomposition of diethyl ketone. However, both ketene and methyl ketene were shown to be present. It appears rather obvious that ketene could not have been a primary decomposition product of diethyl ketone. Preferably, ketene must have been formed by the action of heat upon methyl ketene, which is a primary decomposition product. This would

indicate that the methyl ketene molecule will rupture at the single bond, CH₃—CHCO, to form ketene and ethylene. Undoubtedly, the molecule also is ruptured at the double bond, CH₃CH—CO, to form butylene, or its decomposition products, and carbon monoxide. Both of these decompositions necessarily diminish the yield of methyl ketene.

The explanation that ketene is formed from methyl ketene is substantiated by a comparison of the relative yields of ketene and methyl ketene from the 2 ketones, methylethyl ketone and diethyl ketone. With methylethyl ketone, both acetanilide and propionanilide were formed as reaction products of the ketenes, but propionanilide could not be isolated as such. Diethyl ketone, however, must have given rise to a greater relative ratio of methyl ketene to ketene, because in this case it was possible to isolate propionanilide in the pure state by fractional recrystallization. The relatively lower yield of ketene from diethyl ketone is to be expected because it is formed only as a result of a secondary reaction, whereas two effects conspire to diminish the yield of methyl ketene from methylethyl ketone. The first is the fact that both ketene and methyl ketene are formed concurrently, and the second is that methyl ketene, once formed, is decomposed by heat. As was explained above, the relative yield of ketene is somewhat enriched by this decomposition.

Methyl ketene has been prepared previously by the action of zinc shavings upon  $\alpha$ -bromopropionyl bromide.³ The yield was small. Therefore, the present method is interesting since it is the only other method available by which methyl ketene may be obtained. It possesses the disadvantages that methyl ketene alone is not produced. However, it is anticipated that modifications of the experimental procedure may be found to eliminate the secondary reaction by which ketene is formed.

# Experimental Part

### Purification of the Three Ketones

The acetone was distilled, refluxed with a small quantity of potassium permanganate, and redistilled. The methylethyl ketone was the commercial product, purified by several fractional distillations, and was the same material as that used by Hurd and Kocour. The diethyl ketone was obtained from manufacturers who claimed for it the highest purity. The claim was an optimistic exaggeration; nevertheless, by fractionation, a good portion was obtained which distilled between 102° and 103.5°.

# Apparatus

The apparatus was built in 4 units, the first of which was the decomposition bulb. This, except for minor details, was similar to the apparatus used by Ott and Schmidt⁴ for the preparation of carbon suboxide from diacetyltartaric anhydride. It was blown from

³ Staudinger, Ber., 44, 535 (1911).

⁴ Ott and Schmidt, Ber., 55B, 2126 (1922).

76mm. Pyrex tubing. Such differences in detail as were adopted are as follows. The openings of the 2 glass tubes through which the copper wires entered the apparatus were made gas tight in the following manner. A copper wire was fused to each end of a solid brass rod, 2 cm. long and of the same diameter as the glass tube. One of the wires entered the glass tube and was pulled snugly so that the brass rod touched the glass. This permitted an air-tight seal to be made simply by covering the glass and brass with a piece of rubber tubing. The loose end of this copper wire was sealed to an end of the platinum wire filament. The copper wire, fastened to the other end of the brass rod, was connected with the electric current. The other opening was sealed in identical fashion.

The platinum wire filament was 0.3 mm. in diameter and about 165 cm. in length. The top of the glass support upon which this wire was mounted terminated with a glass handle to which the copper wires were fastened. Instead of employing an annular rubber washer between the ground glass joint of the upper and lower halves of the apparatus, the seal was effected by stopcock grease. Rubber would be essential if a constant high vacuum were to be maintained. That was not essential, nor was it desired in this experiment.

The second unit of the apparatus was a *condensing flask* for the distillate. This was a double-necked, round-bottomed flask, identical with the second unit of Ott's apparatus.⁴

The reaction tube formed the third unit. This consisted of a large U-tube, one arm of which was larger than the other. The small arm was connected to the second unit. The tube was of such capacity that 50 cc. of liquid filled the bottom and extended a short distance up the sides.

The fourth unit was a manometer and a vacuum oil pump. The vacuum was desirable in the apparatus to remove oxygen, to make any possible leaks inward ones, and to maintain a constant, rapid gaseous flow.

# Details of Manipulation and General Remarks

Previous to a run, there were placed in the decomposition bulb the desired amount of ketone, and in the reaction tube an excess of aniline (or toluidine) dissolved in xylene. The 4 units were then assembled and the condensing flask was surrounded by crushed ice. After the evacuation of the whole apparatus to about 20 mm., the electric current was turned on, and the resistance adjusted so that a current of 6 amperes was maintained. An asbestos board was inserted between the first two units. The pressure in the apparatus gradually rose to 300–400 mm. as the reaction progressed. This gain in pressure was characteristic of every run. It prevented a too rapid volatilization of the ketone. The duration of the runs, when a 50cc. sample of ketone was used, was about 2 hours. It was necessary in some cases to apply heat beneath the decomposition bulb to volatilize the final portion of ketone.

The first experiments were conducted in an atmosphere of carbon dioxide, but inasmuch as the results did not differ from those obtained when the original atmosphere before evacuation was air, this procedure was disregarded.

⁵ The copper-to-brass, and the copper-to-platinum joints are readily made with the flame of the blast lamp. The oxidized copper surface is reduced, while hot, by thrusting it into methanol.

⁶ When 2 tubes were used, the second was considerably smaller than the first.

# Decomposition of Acetone

Fifty cc. of acetone was vaporized and heated in the decomposition bulb during the course of 2 hours. The resistance wire was heated by a current of 6 amperes; 28 g. of aniline was used in 2 reaction tubes, 24 g. in the first, and 4 g. in the second. The aniline was diluted with xylene, about 28 cc. being used in the first tube and 6 cc. in the second. It was found that no more than traces of ketene escaped reaction in the first tube.

Nine cc. of distillate was collected in the condenser. For the most part, this was undecomposed acetone.

The xylene and the excess of aniline were removed by distillation. The acetanilide that remained was cooled and crystallized from a mixture of benzene and ligroin; m. p.,  $113-114^{\circ}$ ; yield,  $7.5 \, \mathrm{g}$ , or 9.8%, based upon the acetone that was not recovered.

There was some carbonization in the decomposition bulb.

### Decomposition of Methylethyl Ketone

Reaction with Aniline.—Fifty g. of methylethyl ketone was poured into the first bulb. Somewhat over 21 g. of freshly distilled aniline, diluted with 50 cc. of xylene was inserted in the reaction tube. Only a negligible amount of product was formed in a second reaction tube, placed in series with the first. The current used was 6 amperes; the duration of the experiment was 110 minutes.

Thirteen g. of distillate was collected, 14 cc. of which distilled between 76° and 83°. One cc. of foully smelling liquid remained. This did not solidify at —10°, nor was a solid obtained when part of it was evaporated. A solid was expected because crystals were noticed in the receiving arm of the condensing flask, early in the run; later, these dissolved in some of the liquid distillate. The same occurrence was noted in the decomposition of acetone.

The xylene was evaporated from the reaction product, following which the excess of aniline was removed by steam distillation. A non-volatile oil remained that solidified when the flask was cooled. This solid was filtered out and dissolved in hot alcohol. The aniline evidently had been imperfectly removed, for the addition of an equal volume of water caused the separation of oily crystals. These were collected and discarded; any possible reaction product contained therein was not calculated in the final yield. The filtrate was evaporated upon a watch glass nearly to dryness, and the crystals were collected upon a filter; weight, 2.6 g. The solid was insoluble in cold ligroin, only moderately soluble in cold carbon tetrachloride or in boiling ligroin (110°), and soluble in ethyl acetate. It was divided into 2 fractions by successive recrystallizations from these solvents or from appropriate mixtures of them. The more insoluble fraction was acetanilide; it melted at 110–112°. No purer product could be obtained by further crystallization.

By repeated recrystallizations of the more soluble portion, a fraction was obtained that melted sharply at 79.5–80°. The crystals were needle-shaped, and appeared to be perfectly homogeneous. In spite of the sharp melting point and the apparent homogeneity this material was proved to be not a chemical individual, but a mixture of acetanilide and propionanilide.

Analyses. Subs., 0.1368: CO₂, 0.3578; H₂O, 0.0892. Subs., 0.1551: N, 14.5 cc. (33.9°, 738.6 mm. (30.5°)), 40% KOH used. Calc. for  $C_6H_6N$ —COCH₃: C, 71.1; H, 6.71; N, 10.4. Calc. for  $C_6H_6N$ —COC₂H₅: C, 72.5; H, 7.45; N, 9.40. Found: C, 71.4; H, 7.28; N, 9.8.

An empirical formula, calculated from the observed values, is  $C_{\mathfrak{d} \cdot \mathfrak{d}}H_{\mathfrak{d} \cdot \mathfrak{d}}ON$ . This is seen to be between the two formulas,  $C_{\mathfrak{d}}H_{\mathfrak{d}}ON$  and  $C_{\mathfrak{d}}H_{\mathfrak{d} \cdot \mathfrak{d}}ON$ , required for acetanilide and propionanilide. In the above reaction, these two anilides must have been prepared from the reactions of ketene and methyl ketene with aniline. Further analytical proof

that the gaseous mixture of ketene and methyl ketene was formed is given below in the case of the toluidides.

To secure more evidence to confirm the belief that the 80° material was a mixture, an attempt was made to prepare such a mixture from the pure reagents. Slightly more acetanilide, m. p., 114°, than propionanilide, m. p., 103–104° (see p. 3101), was dissolved in a mixture of carbon tetrachloride and ligroin. The crystals that formed when the mixture was cooled were collected by filtration, and disregarded; m. p., 85–90°. The filtrate, however, was evaporated and the residue crystallized from boiling ligroin. Needle-shaped crystals resulted that melted sharply at 79–80°. These were identical in appearance with those formed in the work with methylethyl ketone. A mixed-melting-point determination of these two sets of 80° crystals gave 79–79.5°.

The 2.6 g. of reaction product corresponds to a yield of 3.7% if the material is assumed to be entirely acetanilide, or 3.4% if it is assumed to be propionanilide. This percentage is somewhat smaller than the true yield, for some of the reaction product was discarded, as explained above.

Reaction with p-Toluidine.—The details of this run were the same as those of the previous one, save that the aniline was replaced by 25 g. of p-toluidine. The p-toluidine had been previously recrystallized from benzene and ligroin. About 29.5 g. of methylethyl ketone entered the reaction; this was shown by the fact that there was 20.5 g. of distillate.

The xylene and the excess of toluidine were removed from the reaction product by vacuum distillation. The residue solidified quickly when cooled. It was crystallized from a mixture of benzene and ligroin. This material, which was later shown to be a mixture of acetotoluidide and propionotoluidide, weighed 3.2 g. Based upon the unrecovered ketone, this corresponds to a 5.3% yield of acetotoluidide, or a 4.8% yield of propionotoluidide.

The mixture was separated into two fractions both by crystallization from a mixture of carbon tetrachloride and ligroin, and by the use of each of these solvents independently. The more insoluble portion was acetotoluidide; m. p., 144°. The more soluble portion, m. p., 105.5–106°, was shown to be a mixture of acetotoluidide and propionotoluidide. The weight of the former was about 3.6 times that of the latter. Therefore, in this reaction, the ratio of methyl ketene to ketene is small.

Analyses (105.5–106° material). Subs., 0.1438:  $CO_2$ , 0.3846;  $H_2O$ , 0.0997. Subs., 0.1629: N, 13.4 cc. (32.5°, 744.3 mm. (31°)), 40% KOH used. Calc. for  $C_7H_8N$ —COCH₃: C, 72.5; H, 7.45; N, 9.40. Calc. for  $C_7H_8N$ —COC₂H₅: C, 73.6; H, 7.98; N, 8.60. Found: C, 73.0; H, 7.75; N, 8.73.

An empirical formula calculated from the experimental values is  $C_{9.8}H_{12.4}ON$ . Acetotoluidide is  $C_9H_{11}ON$  and propionotoluidide is  $C_{10}H_{12}ON$ .

# Decomposition of Diethyl Ketone

Forty g. of diethyl ketone and 14 g. of freshly distilled aniline were placed in the apparatus. The aniline was diluted with 50 cc. of xylene. Six amperes of current was used, and the duration of the experiment was 100 minutes. There was more carbonization on the surface of the decomposition bulb in this experiment than was the case with acetone or with methylethyl ketone, and very little recoverable ketone was found in the distillate. Instead, higher-boiling condensation products were formed. The 13 g. of liquid thus obtained distilled as follows: 2 g. between 100° and 110°; 2 g. between 110° and 124°; 7 g. between 124° and 150°; and 2 g. of higher-boiling residue. Thus, little

⁷ Various reactions of diethyl ketone are discussed by Samec, Monatsh., 28, 739 (1907).

of the ketone which did not decompose into gaseous products escaped decomposition. Twenty-seven g. may have undergone ketenic decomposition.

The xylene and the aniline were removed from the reaction product by vacuum distillation. The residue, which solidified as it cooled, was dissolved in hot carbon tetrachloride and was precipitated by ligroin; weight, 4.8 g. This corresponds to a yield of 10.3% assuming that the material is propionanilide, or 11.3%, assuming that the material is acetanilide. These yields are based upon 27 g. of diethyl ketone. It may be fairer to base the yield upon 40 g., since very little of the ketone was recovered as such. In this case the yields become 7.0% or 7.6%, respectively.

Both propionanilide, m. p., 101.5–102.5°, and acetanilide, m. p., 110–112°, were isolated from the reaction product. The solvents used were carbon tetrachloride and ligroin. Lower-melting mixtures of these two compounds were also obtained in the fractionation.

Propionanilide was prepared for purposes of comparison by refluxing 5 g. of aniline and 8 g. of propionic acid for 5 hours. A white solid was obtained when this liquid mass was poured into 100 cc. of cold water; weight, 6.5 g. A further yield of 0.7 g. was obtained by evaporation of the water. The solid, after recrystallization from a mixture of carbon tetrachloride and ligroin, melted at 103–104°. A mixture of this with equal parts of the 101.5–102.5° material melted at 102–103.5°.

No idea of the relative amounts of acetanilide and propionanilide was obtained. At least, there was enough propionanilide to be easily isolated, but it seemed that there was a greater quantity of acetanilide in the mixture.

### Summary

A further study of the ketenic decomposition of acetone and of methyl ketone has been made. Diethyl ketone, which has not been investigated heretofore in this connection, also was found to decompose ketenically. All three ketones give ketene as a decomposition product. Both methylethyl ketone and diethyl ketone produce methyl ketene, the larger relative yield coming from the latter.

A heating unit is described that differs from the apparatus used in the earlier work. It gives better results with methylethyl ketone and with diethyl ketone; with acetone, however, this is not the case.

Heat apparently ruptures the molecule of methyl ketone at the single bond to give ketene. This conclusion is reached because both ketene and methyl ketene were observed as decomposition products of diethyl ketone, whereas methyl ketene alone is accountable for as a primary decomposition product. The greater yield of methyl ketene when the ketone vapors were heated for a short period of time, in preference to a longer period, is further confirmation of the destructive effect of high temperatures upon methyl ketene. Decomposition undoubtedly occurs at the double bond as well as at the single bond, not to give another ketene as decomposition product, however.

Methyl ketene has been prepared by only one other method. Therefore, the present procedure, in spite of certain drawbacks, should prove to be of value.

## ARSONO-ARYLAMINO ALCOHOLS

By C. W. Rodewald with Roger Adams¹ Received October 3, 1923

During the past few years many new organic arsenic compounds have been made in this Laboratory which have various types of substituted, nitrogen-containing groups in aryl arsonic acids. These have been prepared in order to determine whether the presence of the new groups might not cause a decrease in the toxicity of the products as compared with the corresponding arsanilic acids which may be looked upon as the basic substances of all these derivatives. This communication is a report on a part of this work involving the preparation of certain aryl arsonic acids containing  $\beta$ -hydroxyethylamino and  $\gamma$ -hydroxypropylamino groups. Arsenic compounds containing these groups are of special interest because these groups are found so frequently in naturally occurring and synthetic compounds of marked physiological action.

The procedure for their preparation is similar to that described for other  $\beta$ -arylamino-ethanols and  $\gamma$ -arylamino-propanols described recently by Adams and Segur, and Pierce and Adams. The amino-arylarsonic acids are dissolved in aqueous alkali and treated with  $\beta$ -chloro-ethyl chloroformate, yielding  $\beta$ -chloro-ethyl-(arsono-aryl) carbamates. These latter compounds when refluxed with 2 molecular equivalents of aqueous or alcoholic alkali yield arsono-aryl oxazolidones or when refluxed with excess of aqueous alkali yield the hydrolytic products of the arsono-aryl oxazolidones, namely,  $\beta$ -arsono-aryl amino-ethanols:  $H_2O_3AsC_6H_4NH_2 \longrightarrow H_2O_3AsC_6H_4NHCOOCH_2CH_2 \longrightarrow H_2O_3AsC_6H_4N-OOCH_2CH_2 \longrightarrow H_2O$ 

### HCH2CH2OH.

Analyreac

Various carbamates, oxazolidones or oxazones and  $\beta$ -amino-ethanols or  $\gamma$ -aminopropanols from different o- and p-amino-aryl-arsonic acids were prepared. All of the substances proved to be white crystalline compounds readily made and purified. Every one of these derivatives was less toxic than the corresponding arsanilic acid, but the amino alcohols were the least toxic of the different types of compounds. Moreover, the amino-alcohols were much less toxic than the arsanilic acids from which they were derived, the  $\beta$ -amino-ethanols being slightly less toxic than the corresponding  $\gamma$ -amino-propanols. The toxicities of these compounds were kindly tested by Dr. G. W. Raiziss of the Dermatological Laboratories of Philadelphia.

# Experimental Part

All of the compounds made in this investigation did not have distinct melting points owing to the decomposition which took place at the same time. The figures given, therefore, are those obtained as an average of a number of determinations. By varying the speed of heating the points are varied, sometimes as much as 10°.

 $\beta$ -Chloro-ethyl-(arsono-aryl) Carbamates.—To a solution of 1 molecular equivalent of amino-aryl-arsonic acid in about 8 times its weight of water and one equivalent of sodium hydroxide in 5 N solution was added in small portions with vigorous shaking or mechanical stirring, one molecular equivalent of  $\beta$ -chloro-ethyl chloroformate. Heat was developed during the reaction that took place and the temperature was kept below 35° by immersion of the flask from time to time in an ice-bath. The product separated as a granular precipitate during the course of the reaction. Shaking or stirring was continued for 10 minutes after the addition of the chloroformate in order to make certain of the completion of the reaction. Concd. hydrochloric acid was added in sufficient quantity to dissolve any small amount of unchanged amino-aryl-arsonic acid and the product was then filtered off and washed with water. The substances thus produced were very readily purified by crystallization from 30% acetic acid, forming in every case white needles. The carbamates were soluble in aqueous sodium carbonate or sodium bicarbonate.

3-p-Arsonophenyl-2-oxazolidone, (p)H₂O₃AsC₅H₄NCOOCH₂CH₂.—A mixture of

24 g. of  $\beta$ -chloro-ethyl-(p-arsonophenyl) carbamate with 150 cc. of water and 5.9 g. (2 molecular equivalents) of sodium hydroxide was refluxed for 5 hours. At the end of that time the solution was cooled and concd. hydrochloric acid added until the mixture

was strongly acid to congo red; this caused the solution of any amino-alcohol which might have formed as a by-product during the reaction, and at the same time caused the precipitation of the oxazolidone. The product was filtered, washed with water and purified by crystallization from 30% acetic acid. There was thus obtained 20 g. (95%) of colorless plates melting above 280°.

Analysis. Subs., 03178: 22.36 cc. of 0.0963 N I2. Calc. for C9H10O5NAs: As, 26.13. Found: 25.54.

3-o-Arsonophenyl-2-oxazolidone, (o)H2O3AsC6H4NCOOCH2CH2.—A mixture of

2.1 g. of β-chloro-ethyl-(o-arsonophenyl) carbamate with 2.6 cc. (2 molecular equivalents) of 5 N sodium hydroxide and 20 cc. of water was refluxed for 3 hours. The solution was cooled and acidified with coned. hydrochloric acid until strongly acid. The product separated as a white powder which was purified by crystallization from 20% acetic acid. There was thus obtained 1.3 g. (69%) of colorless plates melting at 212-213° with decomposition.

Analysis. Subs., 0.3630: 25.63 cc. of 0.0963 N I2. Calc. for C9H10O5NAs: As, 26.13, Found: 25.63.

3-p-Arsonophenyl-1,3,2-oxazone, (p)H2O3AsC6H4NCOOCH2CH2CH2.--A mixture

of 4.2 g. of  $\gamma$ -chloropropyl-(p-arsonophenyl) carbamate with 20 cc. of boiling absolute alcohol and 14 cc. (2 molecular equivalents) of a 10% solution of potassium hydroxide in absolute alcohol was refluxed for 2.5 hours. A granular precipitate of potassium chloride started to form at the very beginning and increased in amount until the end of the time mentioned. The mixture was cooled, the granular precipitate filtered off, and hydrogen chloride passed into the alcoholic filtrate until it reacted strongly acid. The solvent was then evaporated and the sol d residue combined with the original precipitate. By treatment of the total solid with dil. sodium hydroxide solution in the cold, the potassium chloride and sodium chloride dissolved, and the product was readily precipitated with an excess of hydrochloric acid. It was purified by crystallization from dil. acetic acid, yielding 2.8 g. (72%) of white plates which melted at 245-247° with decomposition.

Analysis. Subs., 0.2007: 13.52 cc. of 0.0963 N I2. Calc. for C10H12O5NAs: As, 24.58. Found: 24.43.

Arsono-arylamino-ethanols and -propanols.—A  $\beta$ -chloro-ethyl- or  $\gamma$ -chloro-propyl-(arsono-aryl) carbamate was dissolved in 10% aqueous sodium hydroxide containing 5 molecular equivalents of alkali. The solution was refluxed for 4 hours, cooled, and coned, hydrochloric acid added until the mixture was neutral to congo red. The aminoalcohols separated usually as white solids but occasionally as oils which solidified on

standing. The products were filtered, washed with cold water and recrystallized from water. The amino-alcohols thus produced are readily soluble in dil. hydrochloric acid.

They may be formed also by hydrolysis of the corresponding oxazolidone or oxazone but the isolation of these intermediate products is quite unnecessary.

p-Arsonophenyl-β-hydroxyethyl Nitrosamine, (p)H₂O₃AsC₆H₄N(NO)CH₂CH₂-OH.—To a solution of 3.5 g. of β-p-arsonophenyl-amino-ethanol in 6 g. of concd. hydrochloric acid and 6 cc. of water was added a solution of 2 g. of sodium nitrite in 10 cc. of water, with stirring and the mixture then heated to boiling. While still hot it was made alkaline to litmus by addition of 10% sodium hydroxide solution, then cooled and concd. hydrochloric acid was added until the solution was just acid to congo red. A crystalline precipitate separated which was purified by crystallization from water. It formed bright yellow needles which started to darken at 170–175° and melted at 236° with decomposition.

p-Arsonophenyl- $\gamma$ -hydroxy-propyl Nitrosamine, (p)H $_2$ O $_3$ AsC $_6$ H $_4$ N(NO)CH $_2$ CH $_2$ -CH $_2$ OH.—This substance was prepared in a manner exactly analogous to that used for the nitrosamine described above, and formed yellow crystals which were purified from water and melted at 142–143°.

These nitroso compounds gave the expected nitroso-amine reactions.

#### Summary

- 1. Various amino-aryl-arsonic acids were condensed with  $\beta$ -chloro-ethyl- and  $\gamma$ -chloropropyl chloroformates to form the corresponding  $\omega$ -chloro-alkyl-(arsono-aryl) carbamates.
- 2. By treatment with 2 molecular equivalents of aqueous alkali, the  $\beta$ -chloro-ethyl-(arsono-aryl) carbamates were converted into arsono-aryl oxazolidones and the  $\gamma$ -chloropropyl-(arsono-aryl) carbamates into 3-arsono-aryl-1,3,2-oxazones.
- 3. By treatment with excess of aqueous alkali the arsono-aryl-oxazolidones or  $\beta$ -chloro-alkyl-(arsono-aryl) carbamates were converted into arsono-aryl-amino-ethanols and the  $\beta$ -arsono-aryl-1,3,2-oxazones or  $\gamma$ -chloropropyl-(arsono-aryl) carbamates into  $\gamma$ -arsono-aryl-amino-propanols. The arsono-aryl-amino alcohols were much less toxic than the corresponding arsanilic acids.

# THE ANTISEPTIC ACTION OF THE ZINC CHLORIDE SALT OF

By J. W. Howard and F. D. Stimpert Received October 9, 1923

#### Introduction

In connection with the investigation of the use of zinc chloride as a condensing agent in the preparation of anilides our attention was called to the fact that the chemical and physical data in the literature² concerning a possible side product of the reaction, namely the double salt of aniline with zinc chloride  $[(C_6H_5NH_2)_2\ ZnCl_2]$ , were very meager.

This salt further interested us in that it offered an opportunity to compare the bactericidal action of a compound with its constituent compounds.

The medicinal use of zinc chloride is generally that of an antiseptic or disinfectant, being applied either as a solid or in solution.

While aniline has not been used for these purposes, the fact that it is a compound of known toxicity suggested that a study of its bactericidal action might be of value as well as a comparison of this action with that of zinc chloride and with its double salt with zinc chloride.

In order to make the data concerning the salt of aniline with zinc chloride more complete as well as to make the bactericidal comparisons mentioned the following study has been carried out.

# Experimental Part

Zinc Chloride.—Fused, U. S. P. sticks of commercial quality were used in making the solution.

Aniline.—The usual constant-boiling fraction of freshly distilled aniline was used.

Zinc Chloride Salt of Aniline.—Ten g. of aniline was thoroughly mixed with 7.5 g. of finely ground, fused zinc chloride. This mixture was allowed to stand for one hour after the heat of the reaction had subsided. The reaction product was extracted with boiling 95% alcohol, from which the salt readily crystallized on cooling; yield, 11 g.

The needles soften slightly at 230° and melt at 255°. The salt is soluble to the extent of 0.64 g. in 100 cc. of water at 20°; 0.87 g. in 100 cc. of 0.4% hydrochloric acid at 20°; 0.066 g. in 100 cc. of 95% alcohol at 20°. It is also only very slightly soluble in carbon disulfide, chloroform, benzene or ethyl ether. It is somewhat more soluble in methyl alcohol or acetone. It is slowly decomposed by 3 N sodium carbonate solution, readily by 1 N

¹ Presented before the Division of Chemistry of Medicinal Products at the 66th meeting of the American Chemical Society, Milwaukee, Sept. 10-14, 1923.

² Schiff, Jahresber., 1863, 413. Lachowicz and Bandrowski, Monatsh., 9, 512 (1888). Tombeck, Compt. rend., 124, 961-3 (1897). Base, Am. Chem. J., 20, 646 (1898). Hodges, Chem. News, 103, 52 (1911). Reddelien, Ann., 388, 165 (1912).

sodium hydroxide or boiling water. The water solution becomes slightly cloudy on standing for several days at room temperature.

Calc. for C₁₂H₁₄N₂ZnCl₂: N, 8.71. Found: 8.72, 8.75.

Bactericidal Studies.—For this purpose a 6% solution of zinc chloride, a 3% solution of aniline and a 0.6% solution of the zinc chloride salt of aniline were used. The latter two solutions were made in these concentrations because of their limited solubilities in water. The zinc chloride solution was made stronger than the others, as preliminary experiments indicated that this was necessary for comparative purposes.

These solutions were so diluted as to make a total of 5 cc. in each case. To each of these portions of 5 cc. was added 0.1 cc. of a 24-hour broth culture of staphylococcus aureus that had been transplanted on 2 successive days. At 5-minute intervals a 5mm. loop was transplanted from these solutions in 10 cc. of broth and incubated for 48 hours. An examination was made of the broth for positive and negative cultures by cloudiness. These results were then checked by plating 1 cc. of the 48-hour broth culture and incubating for 48 hours. These results were further checked by direct plating from the bacteria suspensions in the original solutions and incubating.

Table I
RESULTS
6% Zinc chloride solution

Dilutions Cc. soln.	Cc. water	ŏ	Time in	minutes	20
5				_	
4	+1	+	+ +	+	
2.5	+2.5	+	+	+	+ (few)
2	+3	+ .	+	+	+ (few)
0.5	+4.5	+	+	+	+
		3% Aniline s	olution		
5			-		
4	+1	+		-	_
3	+2	+	+ 1	-	
2	+3	1 +	+ +	+	
1	+4	+	+	+	+

This would indicate that aniline has about four times the disinfectant power of zinc chloride in solution.

TABLE II

0.6% Solution of zinc chloride salt of aniline
5 cc. of solution

Time in minutes	5 10	15 20	25 30	35
Results	+ +	+ +	+ -	
	(strong) (strong)	(mod.) (few)	(few)	

As this table indicates, there would be no object in diluting this solution further. The colony counts here indicated a gradual but marked decrease

with increase in time. The 15- and 20-minute plates on comparison with the aniline and zinc chloride plates of the same times and dilution show clearly a stronger antiseptic action. Predicting from the curve obtained from the aniline solution, in order to compare on a time basis with the salt solution, the results would seem to indicate that the salt has about 1.3 times the disinfecting power of aniline and about 5 times that of zinc chloride.

When the salt solution was allowed to stand for a week at room temperature, it became somewhat cloudy and lost the power to kill the bacteria in even the 30- or 35-minute periods.

#### Summary

- 1. The double salt of aniline with zinc chloride has been prepared and physical and chemical data have been added to those already existing.
- 2. Its bactericidal action has been found to be greater than that of either aniline or zinc chloride.

MISSOULA, MONTANA

# STUDIES ON REACTIONS RELATING TO CARBOHYDRATES AND POLYSACCHARIDES.¹ V. THE USE OF ACETYLENE FOR THE SYNTHESIS OF CYCLIC ACETALS

By Harold S. Hill² and Harold Hibbert Received October 16, 1923

In a previous communication³ the authors have pointed out the structural relationship existing between cyclic acetals and polysaccharides, that is, that the carbonyl-hydroxyl condensation reaction involved in cyclic acetal formation is without doubt duplicated, either inter- or intramolecularly, or both, when simple sugars condense to form di-, tri-, or polysaccharides. In view of this relationship the belief was expressed that a thorough investigation of the simpler cyclic derivatives would afford a promising means of attack for the problem of the nature of the complex molecules of starch, inulin, cellulose, etc. It is in the course of this work that a new and improved method for the synthesis of cyclic acetals has been developed.

Earlier investigators have prepared cyclic acetals from acetaldehyde and ethylene glycol,⁴ trimethylene glycol,⁴ 1,2-propylene glycol,⁵ glycerol,⁶

- ¹ The title has been altered so as to be more in accord with present, and proposed future investigations (Hibbert).

and mannitol,⁷ by heating mixtures of acetaldehyde (or paracetaldehyde) and polyhydroxy derivatives, either alone or with a catalyst which was usually hydrochloric, sulfuric, or phosphoric acid, or iodine.⁸

In a number of interesting researches, Nieuwland and co-workers^{9,10} have recently shown that various condensation reactions between acetaldehyde and other products (aniline, toluidine, methyl alcohol, ethyl alcohol) take place as well, or better if, instead of using the free aldehyde, this is generated *in situ* from acetylene, catalytically, by the agency of a small amount of a mercuric salt in the presence of sulfuric acid. Thus, by passing the gas into a mixture of an alcohol and the catalyst it was possible to synthesize the simple acetals.

In view of this, it seemed highly probable that the same process might be applied to the preparation of *cyclic* acetals, and it has, in fact, been found that not only are high yields of uniformly pure products more easily and cheaply obtainable at room or moderate temperature, and in a much shorter time by this method, but it is now possible to synthesize readily a number of cyclic acetals, the preparation of which is rendered difficult, and in some cases even precluded, by the unfavorable experimental conditions associated with the earlier methods of formation.¹¹

The procedure used consists essentially in passing acetylene with vigorous stirring into a mixture of a polyhydroxy compound and a small amount of mercuric sulfate and coned. sulfuric acid (93%) as a catalyst. It has been applied with good results to the synthesis of cyclic ethylidene derivatives of ethylene glycol, trimethylene glycol, 1,2-propylene glycol, 1,4-tetramethylene glycol, glycerol- $\alpha$ -bromohydrin, glycerol, 2,3-dimethyl-2,3-butanediol (pinacol), 2-methyl-2,4-pentanediol, and  $\alpha$ -methyl glucoside. Attempts to obtain a similar product from glucose yielded a sirup which could not be crystallized or distilled, but which gave every indication of being an acetal.

Of the above derivatives, ethylidene glycerol was prepared by Harnitzky and Menschutkin⁶ in 1865 by heating glycerol and acetaldehyde together

- 11 The possibility of synthesizing cyclic acetals by the use of acetylene was suggested to Dr. J. A. Nieuwland by the writer some eighteen months ago. He was kind enough to intimate that in view of our greater interest in this particular phase of the subject he would be glad to see the work carried out by us. We desire to express to him and his co-worker, Mr. Hoffmann, our appreciation of the kindness accorded, especially since the latter, due to a misunderstanding, later prepared, independently and almost simultaneously with ourselves, one or two identical acetals, namely, those from trimethylene glycol and pinacone.

In further agreement, and with Dr. Nieuwland's kind consent, it is our intention to extend his acetylene method to the synthesis of cyclic acetals from polyglycols.

at 180° in a sealed tube. Their product boiled at 184–188° and was only slightly soluble in water, whereas the ethylidene glycerol obtained by the new acetylene method boils at 189–195° and is miscible with water in all proportions. Nef¹² also obtained an ethylidene glycerol, soluble in water. It is to be noted in this connection that somewhat the same discrepancies exist between the benzylidene glycerol described by Harnitzky and Menschutkin and that prepared later by Fischer,¹³ and also by Irvine, Macdonald and Soutar.¹⁴ It is probable that in both cases the earlier investigators were dealing with impure products. The question as to whether ethylidene glycerol exists as a 5- or a 6-membered cyclic structure will be taken up in a later paper.

The cyclic acetals of 2,3-dimethyl-2,3-butanediol (pinacol) and of its isomer 2-methyl-2,4-pentanediol, representing 5- and 6-membered rings, have not been obtained previously. Their synthesis by the acetylene method is noteworthy in that the ethylidene cyclization takes place in preference to dehydration and rearrangement to pinacolone derivatives, in spite of the presence of concd. sulfuric acid which presumably should tend to favor the two latter reactions. Both of these acetals are colorless, volatile liquids having a strong odor of camphor and menthol.

The cyclic acetal of 1,4-tetramethylene glycol, I, is also of interest in that it represents a new type of comparatively rare 7-membered ring. 15

The existence and ease of formation of this acetal would seem to indicate that speculations regarding the structure of polysaccharides are by no means limited to the probabilities of only five- and six-membered heterocyclic groups.

- ¹⁴ Irvine, Macdonald and Soutar, J. Chem. Soc., **107**, 344 (1915).
- ¹⁵ As far as can be ascertained this is the only known example of a simple, saturated, heterocyclic structure containing 5 carbon and 2 oxygen ring atoms. In fact, the only 7-membered heterocyclic carbon-oxygen derivatives of any kind appear to be the ε lactone, 2-6-dimethyl-octane-carboxylic-acid-3,8-olid, and its isomer, 5-isopropylheptane-carboxylic-acid-2,7-olid, both isolated by Baeyer and his co-workers [Ber., 29, 29 (1896); 32, 3619 (1899); 32, 3629 (1899); 33, 860 (1900)].

So far as the authors are aware, the crystalline ethylidene product (m. p., 77°) from  $\alpha$ -methyl glucoside is the first acetaldehyde derivative of a sugar to be described, although various benzaldehyde¹⁶ and acetone¹⁷ derivatives of carbohydrates are known. By analogy with other derivatives this ethylidene product presumably has the structure II. The benzylidene derivative of  $\alpha$ -methyl mannoside contains two aldehyde residues, and it is therefore to be expected that diethylidene  $\alpha$ -methyl mannoside will result from the treatment of this glucoside with acetylene. ¹⁸

In the adaptation of the acetylene method of cyclic acetal formation to solid polyhydroxy compounds, such as pinacol,  $\alpha$ -methyl glucoside, and glucose, it was found advantageous to use ethylene glycol as a solvent. The treatment of the solution with acetylene yielded a mixture of the acetals of both the solvent and solute from which the two components were readily separated by distillation.

#### Mechanism of the Reaction

There is no conclusive evidence with regard to the mechanism of the reaction involved in the formation of cyclic acetals from acetylene, although there are two likely possibilities. The first is that acetylene in the presence of mercury salts reacts with traces of water to form acetaldehyde, which in turn condenses with the polyhydroxy compound with regeneration of water. An objection to this scheme lies in the fact that it involves a simultaneous hydration and dehydration which, while not unknown, is hardly plausible, and further that the amount of water present would appear to be too small to account for the rapidity of the reactions, in view of the strong attraction of the acid for it. In every case anhydrous glycols were used, only a small amount of concd. sulfuric acid was added, and the acetylene itself was bubbled through concd. sulfuric acid before it entered the reaction vessel.

A second and more probable alternative is that a direct addition reaction occurs between acetylene and the glycol used. Leaving out of consideration the catalytic role of the mercury salt, for which Nieuwland has postulated an intermediate molecular complex, it would appear that the majority of these acetylene reactions consist essentially in the addition, through the oxygen atom, of an hydroxyl derivative to an unsaturated carbon atom of acetylene with subsequent rearrangement. In the case where dil. sulfuric acid is employed, acetaldehyde is formed, the hydroxy compound in this case being water.

¹⁶ Irvine and Scott, J. Chem. Soc., 103, 575 (1913).

¹⁷ Macdonald, ibid., 103, 1896 (1913).

¹⁸ It is our intention to extend the investigation to other carbohydrates and polysaccharides.

Acetaldehyde

·· -> shows the relative direction of free partial valence force.

With a glycol replacing water in the series of changes given above, similar reactions occur, first, *intermolecularly* between acetylene and one hydroxyl group, and second, *intramolecularly* with the other hydroxyl, the whole transformation being practically instantaneous.

> > Ethylidene ethylene glycol

As to the actual changes which render the acetylene capable of effecting such "addition" reactions, it is possible that these may take place in three stages: (1) the formation of an acetylene-mercury derivative; (2) decomposition of this with removal of the mercury and addition of the elements of sulfuric acid; (3) removal of sulfuric acid and addition of water or glycol.¹⁹

Possibly a similar addition and rearrangement may take place in a variety of reactions involving hydroxyl derivatives, for example: in ester and anhydride formation, etc.

# **Experimental Part**

# Description of Apparatus

Acetylene was supplied from a commercial tank, the gas being first passed into a gasometer in order to afford a means of pressure control and volume measurement.

¹⁹ The fact that dry acetylene can condense directly with anhydrous amines and alcohols, in the presence of concd. sulfuric acid, has been shown by Nieuwland and coworkers. (Refs. 9, 10.)

The arrangement used consisted in mounting two 20-liter glass bottles (having openings at both top and bottom), one above the other. The outlets near the bottom of both were connected by means of heavy rubber tubing, and the securely attached stopper of the lower vessel contained the inlet from the acetylene tank, as well as the outlet leading to the reaction flask, both of these connections being equipped with stopcocks. After the lower bottle was filled with water and this forced into the upper one by means of acetylene from the tank, the valve of the latter was closed, as well as the stopcock on the inlet in order to prevent any leakage taking place through the connection on the tank. An opening to the atmosphere was left in the top of the upper bottle, and in filling the gasometer with acetylene care was taken to admit the gas from the high-pressure tank cautiously and only when the proper stopcocks were open. The amount of gas used was determined from the readings on the lower bottle, this having been calibrated for temperature and pressure to give directly the volume under standard conditions.

From the gasometer the acetylene was passed through a single wash bottle containing concd. sulfuric acid, and from this into the reaction vessel. The latter, in the majority of the experiments described later, was a large-neck, 2-liter, round-bottom flask, having a well-fitted rubber stopper through which passed an inlet tube extending nearly to the bottom of the flask, an outlet tube near the top equipped with a stopcock and a mechanical stirrer. The stirring device operated through a mercury seal, deep enough to hold the maximum gas pressure employed (about 5 cm. of mercury) and was designed to produce a splashing effect so as to insure an efficient mixing of gas and liquid.

#### Description of Method

The preparation of ethylidene ethylene glycol may be taken as illustrative of the acetylene method of synthesizing cyclic acetals.

Four g. of mercuric sulfate was triturated in a mortar with 4 cc. of ordinary concd. sulfuric acid (93%), the resulting paste transferred to 62 g. of pure ethylene glycol while the mixture was cooled and shaken, and the whole then poured into the reaction flask. The stopcock on the outlet tube of the latter was opened and the air in the apparatus displaced by acetylene. The outlet was then closed, the contents vigorously stirred, and acetylene led in under the full pressure of the gasometer. Absorption started at once and the rate increased rapidly as the reaction mixture became less viscous due both to the spontaneous rise in temperature and the progressive transformation of glycol into its acetal.

In the preparation of the majority of cyclic acetals the temperature could be allowed to rise with safety to  $60-70^{\circ}$ , but in the case of such compounds as pinacol,  $\alpha$ -methyl glucoside, etc., it was advisable to operate at a lower temperature, not higher than  $10-25^{\circ}$ , and to use a cooling bath. The time required for the absorption of the calculated amount of acetylene was in general about 30 minutes, this varying somewhat with the nature of the glycol, the temperature used, and the viscosity of the material.

When the required amount of acetylene had been run in, the stirrer was stopped, the flow of gas cut off, the reaction mixture transferred at once to another flask, and the residue washed out with ether. More ether was added and the combined ether solutions were washed once with a 10%

solution of sodium carbonate to neutralize any sulfuric acid present. Since a number of cyclic acetals are soluble in water it is advisable to use as little of the carbonate solution as possible and to extract the wash liquor once or twice with ether. The combined ether solution was dried over solid potassium carbonate, and fractionated through a 30cm. bead column to remove the solvent. In this way 66 g. of ethylidene ethylene glycol, b. p. 82–85°, was obtained. Except for small traces of other derivatives, this was the sole product formed in the reaction. The yield obtained, calculated on the weight of glycol taken, was equal to 75%.

Experiments carried out, using concd. sulfuric acid (93%) to which several per cent. of water had been added, resulted in decreased yields of the ethylidene derivative and the formation of objectionable by-products. Larger amounts of the pure concentrated acid did not favor the yield, and four times the amount employed as above produced considerable charring during the reaction.

Preparation of Ethylidene Trimethylene Glycol. III.—One hundred and fourteen g. of trimethylene glycol gave 115 g. of the cyclic acetal; b. p., 108–111°; yield, 75%. The absorption of gas took place even more rapidly than in the case of ethylene glycol. There were no by-products.

Preparation of Ethylidene 1,2-Propylene Glycol. IV.—One hundred and fourteen g. of glycol yielded 106 g. of the acetal; b. p.,  $92^{\circ}$ ; yield, 70%.

Preparation of Ethylidene Glycerol Bromohydrin. V.—One hundred and fifty-five g. of pure glycerol- $\alpha$ -bromohydrin, b. p. 132° (15 mm.), gave 85 g. of the corresponding cyclic acetal; b. p., 170–182°; yield, 40%. In this experiment the absorption of acety-lene became very slow after about one-half of the calculated amount had been added, and finally ceased altogether. In the ether extract there was a considerable quantity of a higher boiling material which could not be distilled. The bromine atom in the molecule appears to hinder the reaction with acetylene, since the same difficulty was encountered with other bromine derivatives. Ethylidene bromohydrin, however, may be easily prepared with a 70% yield by heating  $\alpha$ -bromohydrin with paracetaldehyde and a trace of iodine as catalyst.³

Preparation of Ethylidene Glycerol. VI or VII.—One hundred thirty-eight g. of glycerol (anhydrous) gave 110 g. of ethylidene derivative; b. p., 189–196°; yield, 63%. In this preparation efficient stirring was rendered difficult on account of the high viscosity of the glycerol, and this resulted in a decrease in the rate of absorption of the acetylene. It was found, however, that by surrounding the reaction flask with a water-bath maintained at about 70°, the speed of the reaction was greatly increased without the produc-

tion of any injurious effect, and in this way the required 34 liters of gas was absorbed in  $1^{1}/_{2}$  hours.

Ethylidene glycerol as prepared by this method, is a colorless, limpid sirup, completely miscible with water, ether, and alcohol. It has only a slight odor when freshly prepared but on standing, especially in moist air, acquires the odor of acetaldehyde. It is hydrolyzed into glycerol and acetaldehyde by dilute acids.

Preparation of Ethylidene 1,4-Tetramethylene Glycol. VIII.—Owing to the small quantity of tetramethylene glycol available because of the difficulties involved in its preparation, this experiment was performed on a small scale. Eighteen g. of the glycol was treated with 4.6 liters of acetylene, using 0.6 cc. of concd. sulfuric acid and 0.8 g. of mercuric sulfate as a catalyst. The addition of the acetylene required several hours, the slow rate of absorption being due to some extent to the inability to stir such a small amount of material efficiently. The ether extract after two fractionations gave 4.6 g. of a colorless liquid, b. p.  $125-127^{\circ}$ , equivalent to a 20% yield. In the flask there remained an equal amount of a thick sirup which could not be distilled but gave every indication of being an acetal, as it yielded acetaldehyde on treatment with acids, etc.

The product boiling at 124–127°, namely, ethylidene tetramethylene glycol, has the same characteristic odor as the cyclic acetals from ethylene and trimethylene glycols, as well as the same general physical and chemical properties. Its boiling point is also in harmony with those of the corresponding acetals from ethylene and trimethylene glycols.

Analyses. Calc. for C₆H₁₂O₂: C, 62.94; H, 10.3. Found: C, 60.9; H, 9.97.

The low value for carbon was doubtless due to a slight amount of impurity, which it was not possible to remove from the acetal due to the small amount of material available for fractionation. The low yield was also due to some extent to the small weight of glycol used, since a parallel experiment on the same scale with ethylene glycol gave a relatively small yield of the corresponding acetal.

Preparation of Ethylidene Pinacol. IX.—Twenty g. of pinacol prepared from pinacol hydrate by dehydrating it over concd. sulfuric acid was dissolved in 30 g. of ethylene glycol, and the solution treated as usual with 16 liters of acetylene, using as catalyst 3 g. of mercuric sulfate and 3 cc. of concd. sulfuric acid. The temperature was kept below 20°, about 1½ hours being required for the absorption of the gas. Careful fractionation of the reaction product gave (a) ethylidene ethylene glycol, 35 g., yield 81%; and (b) ethylidene pinacol, 15 g., b. p. 133-134°; yield, 61%.

Analyses. (b) Calc. for C₈H₁₆O₂: C, 66.66; H, 10.97. Found: C, 66.22; H, 10.97.

The pinacol derivative, unlike the acetals from ethylene, trimethylene and tetramethylene glycols, is only slightly soluble in water, but resembles them in its other properties. It possesses a powerful, camphor-like odor.

Synthesis of Ethylidene 2-Methyl-2,4-Pentanediol. X.—Twenty-nine g. of the glycol²⁰ and the corresponding amount of catalyst, on treatment with 5.6 liters of acetylene gave 27 g. of ethylidene derivative, b. p. 139-140°; yield, 71%. Its properties were almost identical with those of the isomeric ethylidene pinacol.

Analyses. Calc. for C₈H₁₆O₂: C, 66.66; H, 10.97. Found: C, 66.62; H, 11.08.

Synthesis of Mono-ethylidene- $\alpha$ -methyl Glucoside,—Twenty g. of  $\alpha$ -methyl glucoside was dissolved in 80 g. of ethylene glycol, 4 g. of mercuric sulfate and 3 cc. of

²⁰ This glycol was supplied through the kindness of Dr. R. R. Read of the University of Vermont, to whom we wish to express our best thanks.

coned. sulfuric acid were added, and the mixture was treated with 34 liters of acetylene. The temperature was kept below 10° to prevent decomposition of the glucoside by the acid present. As a result of the low temperature the rate of absorption was somewhat slower than in the synthesis of the ethylidene glycols. After the completion of the reaction, ether containing a little absolute alcohol was added, the solution washed with a small amount of a concentrated solution of potassium carbonate, filtered, and then dried over the solid carbonate. The solvents (including ether, alcohol, and the ethylidene glycol formed in the reaction) were removed by distillation, first under atmospheric, and during the later stage, under diminished pressure, in order to maintain a temperature below 60° throughout the operation. The resulting sirup was freed from the last traces of solvents by being kept several days in an evacuated desiccator. In the first preparation the crystallization started slowly and was brought about by exposing the product to the air on a watch glass and rubbing with a glass rod. When once a sample of the solid product had been obtained, the sirups were readily crystallized by "seeding." The crude product was recrystallized from ligroin containing a small amount of dry ether, and obtained as silk-like, white crystals; m. p., 77°.

Analyses. Calc. for C9H16O6: C, 49.0; H, 7.27. Found: C, 48.4; H, 7.22.

Synthesis of Ethylidene Glucose.—The same procedure as used in the preparation of ethylidene- $\alpha$ -methyl glucoside was applied to glucose.²¹ A nearly colorless, very sticky, ether-soluble sirup was obtained which, however, could not be crystallized. It was readily hydrolyzed by means of dilute acids to glucose and acetaldehyde. The sirup was not analyzed.

#### Summary

- 1. A new method has been developed for the preparation of cyclic acetals from polyhydroxy compounds. This consists in passing acetylene gas into the hydroxy derivative (containing a small amount of mercuric sulfate and concd. sulfuric acid, 93%) at room, or at a moderate temperature.
- 2. In the case of solid hydroxy derivatives (pinacol, glucosides, etc.), these are first dissolved in glycol and the resulting ethylidene derivatives then separated by a simple distillation process.
- 3. The mechanism of the reaction possibly consists, at least in part, of an *inter*molecular addition of the glycol to the acetylene, followed by a rearrangement, this being succeeded in turn by an *intra*molecular addition, followed by a second, subsequent rearrangement.

New Haven, Connecticut

²¹ It was observed that pure, dry, powdered glucose when merely mixed with glycol apparently undergoes some physical or chemical change, in that the product sets to a stiff paste, or, with a larger proportion of the glucose, to a solid mass. The phenomenon is being investigated.

# STUDIES ON REACTIONS RELATING TO CARBOHYDRATES AND POLYSACCHARIDES. VI. RELATIVE EASE OF FORMATION OF FIVE- AND SIX-MEMBERED HETEROCYCLIC CARBON-OXYGEN CONFIGURATIONS

By Harold S. Hill¹ and Harold Hibbert Received October 16, 1923

There is probably no more general characteristic of all varieties of sugars and polysaccharides than the recurrence in one form or another of heterocyclic, carbon-oxygen configurations. At the present time, however, the greatest confusion exists concerning the relative stability and ease of formation of the different cyclic structures encountered, so that any evidence of a general character which can be brought forward regarding either of these factors is of importance from both theoretical and practical standpoints. A large amount of work will have to be done before the solution of such a complicated problem may be hoped for, and it is obvious that at the present early stage of the investigation it is desirable first to ascertain the relationships existing between the simplest possible derivatives. The present research is concerned mainly with supplying evidence concerning the relative ease of formation of the ring systems A and B, using for this purpose "partition experiments" by the

new acetylene method for the synthesis of cyclic acetals described in the preceding communication,² (Part V). This consists essentially in passing acetylene into a glycol mixed with a small amount of concd. sulfuric acid and mercuric sulfate, the latter acting as a catalyst.

The "partition principle," as applied to this reaction, is based on the assumption that, when one molecular weight of acetylene is passed into a mixture of one molecular weight of each of two different glycols, the gas will react preferentially, and consequently the amounts of the two cyclic acetals formed will be a relative measure of their ease of formation. The reaction would appear to be admirably suited for such a study since, (1) only traces of by-products are formed; in other words, the acetylene

- ¹ Antoine Chiris Co. Research Fellow.
- ² This Journal, 45, 3108 (1923).
- Michael, J. prakt. Chem., N. F., 60, 341 (1899); Ber., 39, 2138, 2143, 2149, 2153, 2157, 2569, 2785, 2789 (1906); 40, 140 (1907).

reacts only to form cyclic acetals; (2) there is practically no hydrolysis of the acetals to acetaldehyde and glycol, only traces of water being present throughout the reaction; there was also little, or no darkening, indicating the absence of free aldehyde; (3) there is no reverse reaction; (4) the acetylene is supplied only as fast as it reacts.

The objection might be raised that different solubility relationships between the two glycols and their respective acetals might bring about a preferential reaction with the acetylene. Against this view is the fact that, in the experiments on which the conclusions of this paper are based, the materials used, and the products formed, were either all mutually soluble, thereby insuring the presence of one phase throughout, or else their solubilities were so nearly identical as to render it unlikely that a given reaction would be appreciably favored by this factor.

#### Discussion of Experimental Results

In reviewing the evidence it is well to bear in mind the three main factors governing the ease of ring formation in this type of reaction.⁴

⁴ In this connection mention should be made of the investigations of Boeseken in which he attempts to show that the ease of formation of cyclic structures by the interaction of an aldehyde or acetone with a polyhydroxy derivative is dependent largely on the relative spatial positions of the hydroxyl groups about the carbon axis. Such a reaction, it is claimed, takes place readily only when the two hydroxyls involved are on adjacent carbon atoms, and on the same side of the chain. He had previously shown [Ber., 46, 2612 (1913)] that compounds having this configuration, when added to a solution of boric acid, increase its conductivity, and from the results of experiments using this method, concluded that in the simple glycols, such as ethylene, trimethylene and tetramethylene glycol, pinacol, etc., the two hydroxyls are on opposite sides of the chain, while in glycerol and many other polyhydroxy compounds there are two on the same side. He then determined [Rec. trav. chim., 40, 525 (1921)] the equilibrium constants for the reaction of acetone with ethylene glycol, chlorohydrin and glycerol, and found values of K equal to 0.28, 0.14 and 0.77, respectively, thus proving, in his opinion, the marked influence exerted on the ease of ring formation by the spatial position occupied by the hydroxyl groups. A serious objection must be raised to such evidence in that Boeseken, in drawing conclusions from his determinations of equilibrium constants, has apparently disregarded the fact of the widely different energy relationships of the groups H, Cl, and CH2OH, which must in themselves be potent factors in influencing the extent to which the cyclic ketals are formed, and hydrolyzed. It seems rather improbable that the compounds,

would be formed and hydrolyzed with the same ease, regardless of the position of the hydroxyl groups in the free glycol or glycerol. A further objection to Boeseken's view is the ease with which a wide variety of aldehydes react with all the simple glycols, as well as with glycerol and the more complex polyhydroxy compounds. In view of such conflicting evidence, it is considered doubtful that the spatial configuration of the hydroxyl groups in the *simple* 1, 2 and 1, 3 diol derivatives exerts an appreciable influence on the ease of formation of their cyclic acetals.

These are (1) the number of atoms in the ring; (2) the nature of the atoms in the ring; (3) the nature of the atoms or groups attached to the ring atoms.

# Influence on Ring Formation Exerted by the Number of Atoms in the Ring

An experiment involving a partition of acetylene between ethylene glycol and trimethylene glycol showed that the 6-membered cyclic structure, II, is formed in marked preference to that containing 5 ring atoms, I, the ratio being approximately 2:1.

A similar experiment using the isomers, 1,2-propylene and trimethylene glycols, gave almost the same ratio, favoring II over III.

The partition experiment between 2-methyl-2,4-pentanediol and ethylene glycol yielded five times as much of the 6-membered cyclic derivative, IV, as of ethylidene ethylene glycol, I, while when the same experiment was repeated using trimethylene glycol instead of ethylene glycol, the ratio of configuration, IV to that of II, was found to be only about 2: 1. The results of these two experiments, therefore, supply indirect, yet clearly confirmatory evidence that it is primarily the structure (size) of the ring itself which determines the greater ease of formation of II over I.⁵

# The Influence of Groups Attached to the Ring Atoms

Partition experiments, using the acetylene method for the synthesis of cyclic acetals, appear to establish the fact that where formation of similar rings is concerned the presence of methyl groups attached to the glycol carbon atoms favors cyclization. Thus, IV is formed in preference to II

⁵ This is in agreement with the earlier work carried out in this Laboratory by Dr. John A. Timm (not yet published), on the "partition ratios" obtained when using one molecular equivalent of an aldehyde with one equivalent each of a 1,2, and a 1,3 glycol and a small amount of sulfuric acid (40%) as a catalyst.

in the ratio of 2:1. Formation of cyclic acetal IV takes place five times as easily as I, while with II and I, which involve the same rings except for the absence in the former of methyl groups, the ratio is only 2:1.

In harmony with such evidence are the observations of Meyer,⁶ Hjelt⁷ and others,⁸ that (a) tetramethyl- and other alkylated succinic acids form cyclic anhydrides with markedly greater ease than succinic acid itself, and that (b) by Evans,⁹ that methylated cyclic oxides are prepared more readily than those having no methyl groups attached to the ring atoms.

On the other hand, cyclic acetal formation is apparently hindered by the introduction of a second methyl group on the ring carbon of the acetal-dehyde residue. The compound V, for example, could not be prepared by the earlier methods for the synthesis of such derivatives, ¹⁰ although Boeseken, Schaefer and Hermans¹¹ have recently isolated it. ¹²

It is well known that the replacement of two hydrogen atoms by oxygen in a carbon-oxygen heterocyclic structure causes a great decrease in stability of the ring.

$$\begin{array}{c|cccc} CH_2-CH_2 & CH_2-C=O & CH_2-C=O \\ & O & & O & O \\ CH_2-CH_2 & CH_2-CH_2 & CH_2-C=O \\ Stable & Less stable & Least stable \\ \end{array}$$

A replacement of hydrogen by hydroxyl appears to bring about a similar change.

- ¹² It would be interesting to ascertain whether this product V could be prepared by passing allylene (CH₃—C≡CH) into trimethylene glycol in the presence of a mercuric salt. If a positive result were obtained, an experiment employing equimolecular quantities of allylene, acetylene and this glycol should give a partition between V and II, the extent of which would provide definite evidence as to the influence on ease of formation of methyl groups attached to a carbon between two ring oxygens.

The Structure of Ethylidene Glycerol

The greater ease of formation of 6-membered over 5-membered cyclic acetals, in the partition of acetylene between a mixture of 1,2 and 1,3 glycols leads to interesting speculations as to the probable structure of ethylidene glycerol. It has been shown² that this cyclic acetal may be obtained with a yield of 63% by means of the acetylene method, the product boiling within the range  $189-196^{\circ}$ . From the results of partition experiments already mentioned, there is no apparent reason why, in the preparation of the glycerol derivative, there should not be an *intra*molecular partition leading to the formation of configurations VI and VII, with the latter predominating.

With a view to obtaining additional data bearing on this problem, experiments were carried out involving a partition of acetylene between glycerol and ethylene glycol, which gave yields of [VI or VII] and I in a ratio of about 2:1. Using trimethylene glycol and glycerol, the ratio of [VI or VII] to II was a little less than 1:2, and a similar experiment with glycerol and 1,2-propylene glycol showed a marked preference in favor of [VI or VII] over III.

Correlating these results as to their bearing on the configuration of ethylidene glycerol, we find:

- A. If the 5-membered cyclic structure, VI, predominates, it follows from the results of partition experiments that (1) the ease of formation of VI is greater than that of VII; (2) VI than I; (3) VI than III; and (4) that of VI is less than that of II.
- B. If the 6-membered ring, VII, predominates (1') the ease of formation of VII is greater than that of VI; (2') VII than I; (3') VII than III; and (4') that of VII is less than that of II.

Alternative B appears to have the greater weight of supporting evidence. 1', 2' and 3' follow from the generalization that in all the cases investigated,

a 6-membered cyclic ethylidene derivative is formed in preference to a 5-, and 4' is in harmony with the observation that replacement of hydrogen on a ring carbon by hydroxyl causes a decrease in tendency towards cyclization. On the other hand, in A there is no particular evidence favoring 1, 2 and 3.

The conclusion to be drawn from partition experiments, therefore, is that ethylidene glycerol is probably a mixture of VI and VII, with the latter predominating.¹³

It should be borne in mind, however, that *iso* propylidene and benzylidene glycerols, have been shown by Irvine and his pupils ¹⁴ as well as by Fischer ¹⁵ to possess the 5-membered cyclic structures,

Just why these two acetals should have a ring configuration different from that of ethylidene glycerol is not clear, but an explanation may possibly be found in the light of the theory developed by Ingold and Thorpe, ¹⁶ namely, that each group attached to a carbon atom influences the direction of the remaining valence bonds, or forces—the larger groups requiring more space. From this it would follow that the angle  $\alpha$  would be less in VIII and IX than in X, thus accounting for the marked tendency of

acetaldehyde to form the larger ring structure, and also for the fact that acetone does not react readily with trimethylene glycol to give the 6-membered *iso* propylidene derivative, V, while the 5-membered *iso* propylidene ethylene glycol can be readily obtained.

With a methylene group attached to two oxygen atoms, XI, the angle  $\alpha$  would be still larger and, as a matter of fact, methylene glycerol exists in two isomeric forms.¹⁷

#### **Experimental Part**

In each of the following experiments the glycol or glycerol used was pure and dry.

Expt. I. Partition of Acetylene between Ethylene Glycol and Trimethylene Glycol.—A mixture of 93 g. of ethylene glycol and 114 g. of trimethylene glycol was treated

¹³ If this is the case, it is possible that the two acetals may hydrolyze at different rates, which fact would make itself known in the properties of the non-hydrolyzed material. The matter is to be investigated further from this standpoint.

with 33.6 liters of acetylene in the presence of 6 g. of mercuric sulfate and 6 cc. of concd. sulfuric acid. The apparatus and method of procedure were the same as that described in the previous communication.² Special care was exercised in securing as exact a measurement of the gas as possible, and the temperature during absorption was not allowed to rise higher than  $60^{\circ}$ . The final product was extracted with other immediately after the required amount of acetylene had reacted, the resulting lower layer being treated several times with this solvent. The other solution was washed with a small amount of 10% aqueous potassium carbonate, the latter extracted with other, and the combined other solutions were dried over solid potassium carbonate and carefully fractionated using a 30cm. bead column. The product was found to consist almost entirely of other, ethylidene of the glycol (b. p.,  $82-85^{\circ}$ ), and of the ethylene glycol (b. p.,  $107-111^{\circ}$ ), the yields of these two acetals being 40 g. and 91 g., respectively. Calculating the percentage yields on the basis of the total possible amounts of each, it was found that the yield of the ethylene derivative was 30%, and that of the trimethylene derivative was 60%.

It is not claimed that this ratio is more than an approximate measure of the relative amounts of the two cyclic configurations formed by this method, due to the difficulty in this case of separating the cyclic acetals completely.

- Expt. II. Partition of Acetylene between Ethylene Glycol and 1,2-Propylene Glycol.—A mixture of 93 g. of ethylene glycol and 114 g. of 1,2-propylene glycol when treated exactly as in Expt. 1, yielded 100 g. of a mixture of the two corresponding cyclic acetals, boiling within the range 85–91°. It was not possible to separate this mixture into its components which boil at 83° and 92°, respectively.
- Expt. III. Partition of Acetylene between Trimethylene Glycol and 1,2-Propylene Glycol.—From a reaction mixture of 66 g. each of trimethylene glycol, 1,2-propylene glycol and 19 liters of acetylene, involving the same quantities of catalyst as in Expts. I and II and operating under the same experimental conditions, by careful fractionation 45 g. (51%) of ethylidene trimethylene glycol (b. p., 107–111°) and 20 g. (23%) of ethylidene 1,2-propylene glycol (b. p., 92–97°) were obtained.
- Expt. IV. Partition of Acetylene between Ethylene Glycol and 2-Methyl-2,4-pentanediol.—A mixture of 29 g. of the pentane derivative and 15.5 g. of ethylene glycol was allowed to react with 5.6 liters of acetylene in the presence of 1.5 g. of mercuric sulfate and 1.5 cc. of concd. sulfuric acid. The temperature was kept at 20°. Fractionation of the extracted products gave approximately 3 g. (13%) of ethylidene ethylene glycol (b. p., 80-90°) and 22 g. (61%) of ethylidene 2-methyl-2,4-pentanediol, (b. p., 138-140°).
- Expt. V. Partition of Acetylene between Trimethylene Glycol and 2-Methyl-2,4-pentanediol.—A mixture of 29 g. of the pentane derivative and 19 g. of trimethylene glycol with 5.6 liters of acetylene yielded about 6 g. (24%) and 16 g. (44%) of their respective cyclic acetals (b. p., 108-115°, and 138-140°). The amounts of catalyst used were the same as in Expt. IV.

Expt. VI. Partition of Acetylene between Ethylene Glycol and Glycerol.—A mixture of 78 g. of glycerol, 53 g. of ethylene glycol and 19 liters of acetylene with 4 g. of mercuric sulfate and 4 cc. of concd. sulfuric acid gave 52 g. (51%) of ethylidene glycerol (b. p., 189–197°) and 19 g. (25%) of ethylidene ethylene glycol (b. p., 80–90°).

Expt. VII. Partition of Acetylene between Trimethylene Glycol and Glycerol.—A mixture of 79 g. of glycerol, 66 g. of trimethylene glycol and 19 liters of acetylene yielded 27 g. (26%) and 41 g. (47%) of their respective cyclic acetals (b. p., 185–197°, and 106–111°). The quantity of catalyst used was the same as in Expt. VI.

Expt. VIII. Partition of Acetylene between 1,2-Propylene Glycol and Glycerol.—A mixture of 79 g. of glycerol, 66 g. of 1,2-propylene glycol and 19 liters of acetylene, gave 42 g. (40%) of ethylidene glycerol (b. p., 189–196°) and 22 g. (25%) of ethylidene-

1,2-propylene glycol (b. p., 91-96°). There was some difficulty in obtaining a complete separation of the acetals from the unchanged glycols, owing to the mutual solubility of 1,2 propylene glycol and ethylidene glycerol in both ether and the aqueous solution of potassium carbonate used in washing the product. In order to ensure the removal of the unchanged glycol and glycerol, it was necessary to wash the extracted product once with water. This wash liquor undoubtedly contained a certain amount of the soluble ethylidene glycerol so that the actual yield of the glycerol derivative was probably somewhat greater than the amount isolated. There is no doubt, therefore, of the preponderance in this reaction of the formation of this acetal over that of ethylidene-1,2-propylene glycol.

#### Summary

- 1. "Partition experiments" on the formation of cyclic acetals by the action of 1 molecular equivalent of acetylene on a mixture of one equivalent of a 1,2-glycol and one of a 1,3-glycol, indicate that the 6-membered ring forms with considerably greater ease than the 5-membered ring.
- 2. The presence of methyl groups attached to the glycol carbon atoms increases the tendency towards ring formation.
- 3. It seems probable that ethylidene glycerol, as prepared by the acetylene method from glycerol, represents a mixture of a 5- and a 6-membered cyclic acetal, the latter predominating. The product thus represents the final result of an "intramolecular partition reaction."

# STUDIES ON REACTIONS RELATING TO CARBOHYDRATES AND POLYSACCHARIDES. VII. THE EASE OF FORMATION AND NATURE OF CERTAIN SIX, SEVEN, AND LARGER CARBON-OXYGEN CYCLIC STRUCTURES

By Harold S. Hill and Harold Hibbert

RECEIVED OCTOBER 16, 1923

In the preceding communication (Part VI), the question of the relative ease of formation of certain 5- and 6-membered heterocyclic compounds was considered, and evidence submitted showing that cyclic acetals obtained from acetaldehyde and containing 6 ring atoms are formed in marked preference to those having only 5. The present investigation is an extension of this study to derivatives containing more than 6 atoms in the ring.

The importance of further experimental evidence on this subject is at once apparent from a review of the theories which have recently been advanced regarding the molecular configurations of various polysaccharides. Cellulose, for example, is regarded by Karrer² as being a polymerized form of a hypothetical anhydro cellobiose. The latter compound

¹ Antoine Chiris Co. Research Fellow.

² Karrer, Helvetica chim. Acta, 5, 187 (1922).

contains a 13-membered cyclic structure having 11 carbon and 2 oxygen ring atoms. The same investigator assigns to diamylose, and its polymer starch, a similar, 14-membered cyclic configuration. On the other hand, Irvine³ believes that the known facts regarding cellulose are best interpreted on the basis of its complex molecule being derived from an anhydrotriose unit,⁴ consisting of an 18-membered cyclic structure having 15 carbon and 3 oxygen atoms in the ring. Except for these assumptions, there exists at the present time no knowledge regarding the existence of carbonoxygen rings of this size, much less with respect to their properties and the conditions under which they are formed. In fact, examples of simple, carbon-oxygen heterocyclic structures containing even as high as 7 ring atoms are very rare, the most prominent of these being ethylidene tetramethylene glycol prepared recently by the action of acetylene on tetramethylene glycol.⁵

Before taking up the interpretation of the experimental evidence, a brief discussion is necessary of the more important factors involved in the formation of large, cyclic configurations. The problem is obviously complicated by questions such as whether an atom can rotate *freely* on the axis of a single bond, and whether there is a force which tends to keep the atom of a cyclic structure in the same plane. The great influence of these factors on the configuration of a large ring may be illustrated by the use of suitable wire models.⁶

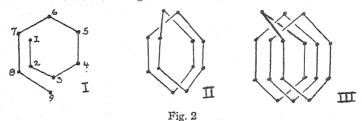

The universal existence and ease of formation of 5- and 6-membered rings would seem in itself to be strong evidence that there is a mutual attraction between all the atoms in a chain, and that it is this force which causes "cyclization." Thus in a given hypothetical case, where the assumption is made of a constant angle of valence forces of approximately 120°, a chain of 3 atoms exists in a configuration illustrated by 1–3; a chain of 4 atoms as 1–4, rather than 1–4′; one with 5 atoms 1–5 instead of 1–5′, etc., and in a 6-membered chain the systematic structure 1–6 rather than one of the large number of possible 1–6′ groupings.

- ³ Irvine, J. Chem. Soc., 123, 525 (1923).
- ⁴ It is of interest that Bertrand has recently succeeded in isolating such a triose complex.
  - ⁵ Hill and Hibbert, This Journal, 45, 3108 (1923).
- ⁶ These can be made by taking a piece of stout iron or brass wire, measuring off, for example, 3 cm., then bending this to form a given angle, say 120°; again measuring off the same distance and bending to form a second similar angle. This typifies the union of 4 atoms. By continuing, a ring may be built up of any number of atoms. It will be noticed, however, that with a larger number of atoms (7, or more) there is a considerable strain on the ring, which is the greater, the larger the number of atoms present. When this strain reaches a certain limit it is relieved by the collapsing of the simple, large ring, to give a more complex, but more stable, spiral configuration such as is indicated in II or III of Fig. 2.

Fig. 1

In other words, a mutual attraction tends to keep the atoms of a chain in one plane and at the same time prevents in some measure free rotation about a single valence linking. The absence of any directing force would allow free rotation on the axis of a single bond with the consequent displacement of the atoms from a plane so that 6' might be located at almost any point in space about 1 within the maximum length of the chain. It is believed that a systematic arrangement, 1–6, is more in harmony with our existing knowledge, than an indefinite zigzag structure⁷ represented by 1–6'. It should be noted that the relative positions of 1 and 6 would be influenced by groups attached to any of the atoms.

If the foregoing conception of the structure of an atomic chain, the atoms of which possess a constant angle of valence forces of 120°, is correct, it follows that a 7-, 8-, 9-, or higher-membered chain would exist in Form I,

the positions of 7, 8, 9, etc., being held near to 1, 2, 3, etc., respectively, by the same mutual forces which determined the configuration of the original ring. The actual forms, therefore, of closed chains containing as high as 12 and 18 ring atoms would resemble the spiral configurations indicated by II and III. In other words, cyclization in atomic chains might be expected to be a periodic function of their length, the period depending on the angles between the valence bonds, or forces, joining the atoms.⁸

⁷ This point is to be discussed by one of us (Hibbert) in a forthcoming paper dealing with the "Mechanism of Organic Reactions."

⁸ The theory would appear to derive some support from the fact that, while tetraand pentamethylene glycols readily dehydrate to give cyclic oxides, the 1-6, 1-7 and 1-8 diols do not show this property. 1-10-Decamethylene glycol, however, may be The higher periods would be less sharply defined than the first, since the greater the number of atoms in a closed chain, the less would be the strain produced by the addition or subtraction of a single atom.

The possibility of spiral ring formation was suggested by Frankland⁹ and has been emphasized by Pickard, Kenyon and co-workers,¹⁰ in their interesting researches on the dependence of rotatory power on chemical constitution. The latter show¹¹ that "in a series of normal esters of secondary alcohols exhibiting optical activity we may expect irregularities in the rotatory power... and that these irregularities are due to the fact that the ester chain of carbon atoms assumes a spiral form with about five atoms in one complete turn, entire turns being completed at the point of irregularity."

# Relative Ease of Formation of 5-, 6- and 7-Membered Cyclic Acetals

It was of primary importance to establish definitely the existence of the first period in the tendency towards ring closure. Consequently, the relative ease of formation of 5-, 6- and 7-membered cyclic acetals resulting from the action of acetylene, in the presence of a catalyst, on ethylene glycol, trimethylene glycol and tetramethylene glycol, respectively, was first investigated. It has already been shown in the last communication 12 that it is possible to apply the "partition principle" to this reaction, and that one mole of acetylene, when caused to react with a mixture of one mole of ethylene glycol, and one mole of trimethylene glycol, combines more readily with the latter, the ratio of the 6-membered cyclic structure to the 5, being approximately two to one. A similar experiment involving a partition of one mole of acetylene between one mole each of ethylene glycol and tetramethylene glycol now shows that the penta-atomic ring is formed three times as readily as the acetal containing 7 ring atoms. The existence of an optimum in the ease of ring formation with this series of compounds is therefore clearly demonstrated.

# Attempts to Prepare Cyclic Acetals Containing More than Seven Ring Atoms

The rapid decrease in the ease of ring closure in hepta-atomic configurations renders it difficult to account for the formation and stability of the much larger ring systems which are assumed to exist in the polysaccharides converted into a cyclic oxide, indicating a second period in the tendency toward cyclization. Some doubt exists as to the actual configuration of decamethylene oxide, so that the evidence is not conclusive. This product is to be investigated as well as the higher members of the glycol and polyglycol series and their cyclic acetals.

except on the ground that, with sufficient lengthening of a chain, there is a recurrence of the tendency towards "cyclization." Estimating that the second "period" of ring formation in this series of cyclic acetals would occur in structures having from 11 to 13 ring atoms, an attempt was made to prepare the cyclic ethylidene derivatives of octa- and decamethylene glycols. The method used was that in which a mixture of a glycol and paracetaldehyde is heated in the presence of a trace of 40% sulfuric acid as a catalyst. Both octa- and decamethylene glycol yielded heavy, sirupy. odorless acetals which had very high and indefinite boiling points, the latter property indicating that polymerization had probably occurred. since the simpler cyclic acetals containing 5, 6, and 7 ring atoms are limpid. volatile liquids, possessing a characteristic odor. It has not yet been possible to prove definitely whether the sirups obtained from the higher glycols are cyclic structures or open-chain derivatives of indefinite size resulting from successive glycol-acetaldehyde condensations, such as  $HO-(CH_2)_9-CH_2-O-CH(CH_3)-O-CH_2-(CH_2)_9-O-CH(CH_3)-O$ -CH₂-(CH₂)₉OH, etc. Analysis for carbon and hydrogen gave values reasonably close to those calculated for the cyclic acetal, which are somewhat below the percentages of carbon and hydrogen in an open chain of the type mentioned above. In view of other possible configurations, however, it is not considered possible to differentiate by analysis alone between the cyclic and open-chain alternatives.

If our conception of large atomic rings as closed spirals (II and III) is correct, the different physical properties of the ethylidene compounds of octa- and decamethylene glycols from those of the lower homologs cannot be considered as evidence against the existence of the former in cyclic form. It is to be expected that a change of molecular structure from a simple ring to a dicyclic, closed spiral would give rise to compounds having totally different physical properties.¹³

13 In this connection it is interesting to note that in the homologous series of cyclic anhydrides of dibasic acids there is a sharply marked break in physical properties [Auger, Ann. chim. phys., [6] 22, 362 (1891). Etaix, ibid., [7] 9, 370, 387, 398, 404 (1896). Michael, J. prakt. Chem., [2] 60, 337 (1899). Voerman, Rec. trav. chim., 23, 265 (1904). Einhorn and von Diesbach, Ber., 39, 1222 (1906). Einhorn, Ann., 359, 150, 158 (1908). Staudinger and Ott, Ber., 41, 2208, 3829 (1908). Staudinger and Bereza, Ber., 41, 4462 (1908). Diels and Lalin, Ber., 41, 3429 (1908)] between succinic and glutaric anhydrides on the one hand, and adipic and the higher members on the other. The two former derivatives contain 5- and 6-membered heterocyclic configurations and closely resemble each other in their properties, being characterized by their tendency to form large crystals, and their ready solubility in solvents. Adipic anhydride differs from glutaric from a chemical standpoint only in the addition of another CH₂ group, yet this compound and the higher homologs have practically no crystalline form and are insoluble in many solvents. More important, still, is the fact that the 7- and higher-membered cyclic anhydrides exist for the most part only in a polymerized condition, while succinic and glutaric anhydrides do not polymerize. These

The suggestion is offered that "cyclization" of long chains to give closed spiral configurations is closely connected with the phenomenon of polymerization. It is difficult to explain this change in the case of polysaccharides in any other way.¹⁴ For example, Karrer's diamylose (anhydro maltose) differs from maltose itself only in that: (1) a new half-acetal type of linkage is introduced by the dehydration, and (2) a closed chain of 14 atoms has been formed. Since there are already three analogous linkages in maltose, the introduction of a fourth group of this inert type could scarcely be expected to produce any great change in properties. It is probable, therefore, that the formation of the 14-membered ring is alone responsible for the tendency of diamylose to polymerize. Furthermore, since most of the known examples of simple, cyclic structures do not polymerize, it is unlikely that merely increasing the number of ring atoms to form simple large rings would cause this property to appear. The conclusion is reached that the longer closed chains exist in the alternative, closed-spiral configurations, and that it is the greatly increased complexity of the latter which in some way (possibly an interlocking as suggested by Robinson)¹⁵ brings about polymerization.

Similar reasoning may be applied to the polymerization of the 18-membered cyclic structure of the anhydro-triose suggested by Irvine as the unit on which the cellulose complex is built up.

On the whole it appears probable that the acetal sirups obtained from the action of acetaldehyde on octa- and decamethylene glycols are polymerized forms of 11-, and 13-membered ring structures.

The present investigation was rendered difficult by the laborious processes necessary for the preparation of the higher glycols. The three which have been tried with the acetal reaction were made only in small facts would seem to indicate that the addition of a CH₂ group into the molecule of glutaric anhydride does not give rise merely to an increase in size of a simple ring, but that the 7-membered closed chain assumes an entirely different molecular configuration. A logical explanation is that simple atomic rings above a certain size become strained to a point where the structure collapses to a more stable but more complex form, the valence bonds remaining intact. This would account for the sharp change in physical properties without a corresponding break in the chemical nature of members of a homologous series.

14 The phenomenon of polymerization is one of the most important with which chemists have to deal, and at the same time, one of the least understood. It plays a leading role in animal metabolism, plant life, and industrial processes and in fact, penetrates to the roots of our very existence. It seems useless, however, to expect an understanding of the nature of the more complicated, polymerized products, such as cellulose, starch, etc., and of the factors giving rise to their formation, until the simpler cases, such as the polymerization of ethylene oxide, have been examined, and an explanation furnished. An investigation of these simpler derivatives is in progress. (Hibbert.)

¹⁵ Robinson, J. Soc. Chem. Ind., 42, 953 (1923).

amounts. It is proposed to synthesize a series of glycols, trimethylene to decamethylene, and higher if possible, as well as polyglycols, and to make a more exhaustive study of the heterocyclic structures which may be derived from them.

## Experimental Part

## Preparation of 1,4-Tetramethylene Glycol

Tetramethylene glycol was synthesized from trimethylene glycol, by first converting it into tetramethylene bromide by the method of Marvel and Tanenbaum. The reduction of the ester was the most troublesome step, but after the technical difficulties had been overcome, the method gave a yield of 60-72%. Efficient stirring appears to be of the greatest importance.

The tetramethylene bromide was converted into the diacetate by means of the procedure given by Henry¹⁷ for the similar synthesis of trimethylene diacetate. A mixture of 100 g. of tetramethylene bromide, 125 g. of potassium acetate and 225 cc. of 90% ethyl alcohol was heated for 14 hours on a steam-bath. The cooled solution was filtered from the solid potassium bromide, and the greater part of the alcohol distilled. Two layers separated, the lower of which was extracted with ether and the latter solution added to the upper layer which was then distilled under diminished pressure. After the last of the alcohol had been removed, a certain amount of potassium acetate separated. The distillation was stopped, ether added, the mixture filtered, and the ether removed. Fractionation of the solution under diminished pressure yielded 76 g. of tetramethylene acetate, b. p., 106–112°, representing a 95% yield of fairly pure material.

The diacetate was converted into tetramethylene glycol by heating with powdered potassium hydroxide¹⁷ and distilling the resulting glycol directly from the reaction mixture, under diminished pressure. The yields were poor, 34 g. of diacetate with 24 g. of potassium hydroxide giving only 9.5 g. of purified glycol, and representing a 50% yield. Calcium or barium hydroxide, in place of potassium hydroxide gave no better results.

Preparation of Ethylidene Tetramethylene Glycol.—This cyclic acetal has already been prepared from the glycol by means of acetylene and a trace of mercuric sulfate and coned. sulfuric acid.¹⁸ It may also be obtained by the following method. A mixture of 11.6 g. of tetramethylene glycol, 10 g. of paraldehyde (added from time to time) and one drop of 40% sulfuric acid was heated for 10 hours on the water-bath. The product was extracted with ether, washed with a small amount of 10% sodium carbonate solution, dried over solid potassium carbonate and fractionated. There was obtained 4 g. of ethylidene tetramethylene glycol; b. p., 125–127°; yield, 27%. There was about an equal amount of a sirup left in the flask which could not be distilled, but which was an acetal of some kind, since it was readily hydrolyzed by dilute acids into acetaldehyde and tetramethylene glycol.

Partition of Acetylene between Ethylene Glycol and 1, 4-Tetramethylene Glycol.— The procedure employed for this experiment was identical with that already described in a similar determination of the "partition value" between ethylene glycol and trimethylene glycol.¹⁹

A mixture of 18 g. of tetramethylene glycol, 12.4 g. of ethylene glycol and 4.4 liters of acetylene (the calculated amount) with 1 g. of mercuric sulfate and 1 cc. of concd. sulfuric acid as catalyst, gave 4.6 g. (b. p., 80–90°) and 2 g. (b. p., 120–130°) of the

¹⁹ This series, Part VI, THIS JOURNAL, 45, 3117 (1923).

respective cyclic acetals, representing yields of 26.0% and 8.5% of the 5- and 7-membered ring derivatives, respectively. It is not claimed that these yields are more than approximations, although there is no doubt of the preponderance of the smaller cyclic ring derivative.

Preparation of Decamethylene Glycol.—Dimethyl sebacate was prepared by heating a mixture of 5 parts by weight of sebacic acid, 2 parts of methyl alcohol and 4 parts of concd. sulfuric acid for 15 hours. The product was poured into an excess of water, extracted with ether, and distilled under diminished pressure; yield of pure dimethyl ester, 90-95%; b. p., 167-168° (15 mm.).

It was found that Marvel and Tanenbaum's modification ¹⁶ of the reduction method developed by Levene and Allen ²⁰ may be applied, satisfactorily to the reduction of dibasic esters. Ninety g. of dimethyl sebacate was reduced with 138 g. of sodium, 320 cc. of toluene and 780 cc. of absolute ethyl alcohol. The yield of decamethylene glycol, m. p., 72°, was 41 g. or 60%. The procedure followed was approximately that given by Marvel and Tanenbaum for the reduction of ethyl phenoxybutyrate. ¹⁶ After the distillation of alcohol and toluene from the reaction mixture, 600 cc. of water was added and the crude solution extracted five times with ether. Evaporation of the solvent left crude decamethylene glycol which was recrystallized from a mixture of ligroin and benzene.

Preparation of Ethylidene Decamethylene Glycol, 
$$CH_3-CH_4-CH_2$$
 ??

—Eighteen g. of decamethylene glycol, 15 g. of paracetaldehyde and 4 drops of 40% sulfuric acid were heated together for 12 hours under a reflux condenser. More paracetaldehyde (10 g.) was then added to replace loss by volatilization and the heating continued for another 12 hours. The product was treated with ether, the solution washed with a small amount of 10% sodium carbonate solution and dried over solid potassium carbonate. Removal of the solvent left a viscous, colorless sirup which was fractionated under diminished pressure. The small first fraction, boiling at  $138-140^\circ$ , was found to be unchanged glycol. At  $230^\circ$  (0.5 mm.) a sirup began to distil, and the temperature rose steadily to  $320^\circ$  (0.5 mm.) at which point the distillation was stopped. The greater part of the product still remained in the flask as a colorless sirup. There had been no apparent decomposition, although the product was somewhat more viscous than at the start of the distillation. This fact, together with the rise in boiling point would seem to indicate that a polymerization of the product had been brought about by heating.

Analyses [distilled sirup, b. p.,  $230-320^{\circ}$  (0.5 mm.)]. Calc. for ethylidene decamethylene glycol,  $C_{12}H_{24}O_2$ : C, 72.00; H, 12.0. Found: C, 71.16; H, 11.8. Sirupy residue. Found: C, 71.41; H, 11.9.

Both sirups were readily hydrolyzed to acetaldehyde and decamethylene glycol by treatment with dilute acids.

Preparation of Octamethylene Glycol.—Suberic acid was obtained from castor oil by oxidizing this with nitric acid according to the method given by Markownikoff.³¹ The yield of pure acid was only about 5-6% of the weight of oil used, although earlier investigators record a higher yield.

A mixture of 115 g. of pure suberic acid (m. p., 141°) with 230 g. of methyl alcohol and 75 g. of concd. sulfuric acid was heated for six hours under a reflux condenser. The yield of dimethyl suberate, [b. p., 136-138° (14 mm.)] was 87 g., or 62%.

Dimethyl suberate was converted into octamethylene glycol by the same method

²⁰ Levene and Allen, J. Biol. Chem., 27, 435, 443 (1916); 33, 509 (1918).

²¹ Markownikoff, Ber., 26, II, 3090 (1893).

and procedure as followed in the reduction of dimethyl sebacate ester; 80 g. of dimethyl suberate, on reduction with 138 g. of sodium, 780 cc. of absolute ethyl alcohol and 320 cc. of toluene, gave 33 g. of pure octamethylene glycol; b. p., 167–168° (15 mm.); m. p., 63°; yield, 55%. Because of the greater solubility of this glycol in water, eight extractions with ether were necessary in order to remove it completely from the crude, aqueous salt solution. Prior to this extraction only the minimum amount of water necessary to dissolve part of the solid products had been added to the residue left after removal of the alcohol and toluene.

Preparation of Ethylidene Octamethylene Glycol,  $\begin{bmatrix} \mathrm{CH_3-CH} \\ \mathrm{CH_3-CH_2} \end{bmatrix}_{x}^{?}$ 

—A mixture of 19 g. of octamethylene glycol, an excess of paraldehyde (25 g.) added from time to time, and 6 drops of 40% sulfuric acid was heated for 12 hours under a reflux condenser. Extraction with ether, as in the preparation of the decamethylene derivative, yielded similar products, namely, a small amount of unchanged glycol, and a sirup having an indefinite, very high boiling point. The latter material was not analyzed, but appeared to be analogous to the sirup obtained from the reaction of acetaldehyde with decamethylene glycol, being readily hydrolyzed to the free aldehyde and glycol by means of dilute acids.

The authors desire to express their thanks to the Antoine Chiris Company, through whose generosity the work described in Parts V, VI and VII, was rendered possible. They also wish to express their gratitude to the Committee of the Warren Fund, National Academy of Sciences, for the grant made to them for the purchase of chemicals used in the course of these investigations.

### Summary

- 1. A discussion is given of ring formation and of the properties of cyclic acetals derived from high-membered glycols (1:4; 1:8; 1:10).
- 2. It is shown that the ease of formation increases from the 5- to the 6-membered rings and then diminishes again with the 7-.
- 3. It is suggested that due to the strain involved in the structures of higher-membered cyclic acetal rings, these collapse, and assume a "spiral ring formation." The tendency of atomic chains to assume the latter is probably a periodic function of the number of atoms in the chain. The properties of the individual atoms in such spiral ring formations probably vary in a "periodic manner."
- 4. The "tendency towards polymerization" and "that of long chains to undergo cyclization to give closed-spiral configurations" probably stand in intimate connection with each other.
- 5. It is considered probable that the condensation products derived from acetaldehyde and octa- and decamethylene glycol, respectively, represent polymerized cyclic acetals of the "closed-spiral type."
- 6. The possibility of the existence of starch, cellulose, etc., as polymerized, closed-spiral configurations may serve to account for the stability of such ring complexes.

#### THE AUTO-OXIDATION OF CHLOROFORM

By A. M. Clover Received October 19, 1923

Pure chloroform is known to be decomposed by the air with the formation of hydrochloric acid, phosgene and carbon dioxide.¹ The development of an oxidizing substance has also been noted and this has been referred to previously as chlorine. The literature on the subject has been brought together by Baskerville.²

As no proof exists that the oxidizing substance is chlorine, and further, as the formation of phosgene and carbon dioxide leaves no doubt that the reaction is one of oxidation, the writer was led to a study of the question, suspecting that we have here an example of peroxidation similar to that which occurs with benzaldehyde and with ethers.³

When pure4 chloroform is exposed in such a manner that it comes in contact with a sufficient supply of air, it is decomposed at a remarkable rate, a fairly good idea of which may be obtained by following the development of acidity and also of the oxidizing substance which has previously been called chlorine. A maximum rate of oxidation is obtained by filling glass-stoppered bottles to one-third of their volume and allowing them to stand in diffused light. For reasons which will become obvious later, no experiments were made in sunlight. The reaction proceeds slowly at first and the rate gradually increases from day to day. At the end of a period varying from 3 to 4 weeks the development of oxidizing substance reaches a maximum at which time the solution has frequently become hazy and green. Soon afterward nearly all of the oxidizing substance disappears. When at its maximum the solution is usually close to 0.2 N in oxidizing strength, which may be measured by its action upon acidified potassium iodide solution. During the first two weeks of the oxidation the acidity developed was about twice that of the oxidizing value. After this time the acidity showed a relative increase in value. It was measured by dissolving 1 cc. of the chloroform in 400 cc. of water and titrating with standard sodium hydroxide solution, until a permanent color was produced with phenolphthalein. Of course, this method caused the hydrolysis of phosgene or any other substance capable of hydrolysis.

- ⁴ All chloroform used in this work was purified by shaking the commercial product thoroughly with an equal volume of water thrice, drying it twice with calcium chloride in a filled bottle of amber glass and then distilling. A product so purified was usually free from oxidizing substance and contained only a slight trace of free acid; when this was not the case it was discarded.

Although the accumulation of oxidizing substance ceased after a few weeks, there was no decrease in the rate of decomposition of the chloroform, for the acidity continued to increase rapidly. One sample which was not exceptional became more than N in acidity in six weeks.

When the pure chloroform was saturated with water the decomposition was found to take place more rapidly, as indicated by the acidity which in one experiment became  $1.7\ N$  after an exposure of six weeks. At no time during this period was there present more than a very small amount of oxidizing substance.

It has already been observed in the case of ethers that a relatively small amount of auto-oxidation takes place in amber glass when compared with flint glass. With chloroform the rate in amber is nearly one-half that in the flint. However, the accumulation of oxidizing substance goes much further in the amber and in one experiment reached a strength of  $0.6\ N$  in about two months. At this point the strength began to fall off rapidly. Undoubtedly, light is a factor in both the formation and decomposition of the oxidizing substance.

Some experiments were carried out in an atmosphere of dry air but the results did not differ much from those previously obtained without this precaution.

# Nature of the Oxidizing Substance

After it was learned that the oxidizing substance accumulates only for a limited time and then disappears, it was possible to select solutions of considerable strength at the proper time. When such a solution was added to water the latter showed a decided test for hydrogen peroxide by means of chromic acid. By comparing the strengths of colors obtained in such experiments with those obtained with very dilute solutions of hydrogen peroxide of known strength, it was possible to learn approximately the amount of this substance obtained from the oxidized chloroform. In this way, it was determined that the amount of hydrogen peroxide which resulted from the treatment with water depended largely upon the amount of water used. When the latter was in sufficient quantity to yield a solution of about 1 part in 100,000 the yield obtained was close to 80% of the oxidizing substance contained in the chloroform. When a limited amount of water was used the yield was only a small fraction of this.

The fact noted in the preceding paragraph suggests that the hydrogen peroxide does not exist in the chloroform as such, but that it is formed by reaction with the oxidizing substance upon water. This view is confirmed by the fact that hydrogen peroxide is only very slightly soluble in chloroform. An aqueous solution of the peroxide containing about 38% of the latter was shaken thoroughly with an equal volume of chloroform. The latter was 0.008~N in active oxygen, which is only a very small

fraction of the oxidizing strength of the chloroform solutions under consideration.

Furthermore, the behavior of the oxidizing substance toward a solution of potassium iodide leaves no doubt that the hydrogen peroxide was formed through reaction with water. When the oxidized chloroform is added directly to a dilute acidified solution of potassium iodide the liberation of iodine is rapid and complete within the least time possible to make a titration. When the experiment is repeated with all factors unchanged except that the chloroform solution is first added to the water and shaken, the addition of acidified potassium iodide then results in a very slow liberation of iodine in a manner characteristic of hydrogen peroxide. The direct action of the oxidizing substance is that of a much more powerful agent, being similar to that of chlorine or hypochlorous acid.

It may be concluded that the oxidizing substance is a peroxide which is formed directly by the peroxidation of the chloroform. The fact that a good yield of hydrogen peroxide is obtained through hydrolysis only in very dilute solution makes it impracticable to isolate a considerable quantity of this substance. There is evidence of a small amount of free chlorine in the hydrolyzed product as shown by the immediate action upon potassium iodide in dilute solution. Perhaps this chlorine existed along with the peroxide in the chloroform, having been formed from it as a decomposition product. The stronger solutions of peroxide which were obtained in amber bottles always had a green color. This color disappeared on partial evaporation of the solvent as did also the characteristic action upon potassium iodide. The large loss of active oxygen which occurs when the peroxide is treated with a limited amount of water can be explained only by assuming the escape of this oxygen as gas. Chlorine is found in such a solution only to a very small extent.

It was anticipated that the peroxide could be isolated by evaporation of the unchanged chloroform. Although the strength of the peroxide solution is increased by this process, still there is much loss of peroxide and all of the latter disappears soon after removal of the solvent. The amount of residue is almost negligible. Several ether peroxides have been obtained as approximately pure residues upon evaporation of the unchanged ethers, but as the experience with chloroform is so decidedly different it seems likely that in the latter case peroxide formation does not consist in the simple addition of oxygen alone but also in the separation of hydrochloric acid as follows:  $CHCl_3 + O_2 = CO_2Cl_2 + HCI$ . It would be very difficult to prove that hydrochloric acid is formed in the primary action of peroxidation, but there can be no doubt about the presence of a monocarbon peroxide derivative which can be explained

satisfactorily only by the formula, Cl₂=C(), dichloro-carbon-peroxide.

#### Preservatives or Anticatalysts

It has been the general custom for many years to preserve chloroform by the addition of 0.5 to 1% of alcohol, and this method seems to have given perfect satisfaction so far as the development of objectionable decomposition products is concerned. It has not been shown whether the alcohol acts as an anticatalyst, preventing the oxidation of the chloroform, or whether it destroys the objectionable products by entering into reaction with them. This question has been discussed by Baskerville⁵ who has collected the literature on the subject.

In studying the action of alcohol the writer has been especially impressed by the small amount of this substance necessary to prevent the formation of even a trace of peroxide, phosgene or acid. It has been found repeatedly that pure chloroform containing 0.25% of alcohol after standing for three months in diffused light under conditions most favorable to oxidation, shows no trace of the above mentioned impurities. Starch solution was employed in testing for peroxide. The acidity was determined by the use of 0.01 N alkali. The initial acidity of the purified chloroform was usually such that 4 or 5 drops of 0.01 N sodium hydroxide were required to produce a permanent color with phenolphthalein when 1 cc. of the chloroform was dissolved in water which had been previously brought to a definite color with alkali. It will be recalled that without the addition of alcohol to the chloroform a very high acidity would have been shown by the latter at the end of six weeks. It is difficult to understand how the presence of so small an amount of alcohol could prevent, by ordinary reaction, the formation of a trace of acid. However, alcohol in sufficient quantity does destroy peroxide which has developed in pure chloroform, but a high degree of acidity remains. A sample in which the oxidation had proceeded for less than two weeks and in which the acid value was, according to previous experience, not much more than twice the oxidizing value, was treated with about 2% of alcohol. After about one-half hour the solution became turbid. In two hours practically all peroxide had disappeared but the acidity was nearly as great as it was before the alcohol was added. This experiment also confirms the conclusion previously reached, that no hydrogen peroxide is present for this would not have been destroyed.

When alcohol was used as a preservative in the proportion of 1 to 1000, a trace of peroxide was first noticeable at the end of 6 weeks when there was also found to be a small increase in the acidity of the chloroform. At 1 to 2000 the alcohol was less effective as a preservative, for the same result was obtained after about one week.

Other Preservatives.—Some other substances besides alcohol are known to have a preservative action upon chloroform. The writer se-

⁵ Baskerville, J. Ind. Eng. Chem., 4, 364 (1912).

lected for study several common organic substances of different types with the hope of throwing additional light upon the question of the role of the preservative.

Phenol, benzyl alcohol, petroleum ether, purified liquid petrolatum and methyl alcohol have been found to be very effective. Different samples of chloroform containing 1% of these substances were exposed in the usual manner for a period of five months. At no time was it possible to obtain even a slight coloration by means of potassium iodide and starch; also, not even a slight increase in the acidity could be detected in any case. It is thought that all of these substances would be perfectly effective at a greater dilution, but this has not been carefully tested except in the case of the petroleum oils.

The phenol solution was finally evaporated in a current of air. The residue was not colored and it dissolved completely in water. It was converted into 2,4,6-tribromophenol, which was found to be pure after recrystallization from dil. acetic acid; m. p., 93°.

The petrolatum solution was finally evaporated and all chloroform was removed from the residue by repeatedly adding alcohol to it and distilling off the alcohol. Finally, the residue was tested for chlorine by means of copper oxide, with negative results.

These effective preservatives represent greatly different types of substances, and it is apparent that chemical structure is not an important factor in the preserving action. As to the question of a chemical change in the preservative, the results here are in agreement with the experience with alcohol. It has not been possible to show the presence of any substance which might be expected to be formed by the oxidation or chlorination of the preservatives.

Further experiments with the petroleum oils have shown that these are considerably more effective than alcohol and this is especially significant because the former are so resistant to chemical change. Pure chloroform containing 1 part of petroleum ether in 1000 was under observation for three and a half months, during which no trace of peroxide could be detected. The same result was obtained with liquid petrolatum. At a dilution of 1 part in 2000 a trace of peroxide first appeared with liquid petrolatum after five weeks. With petroleum ether, the result was not quite so good.

Benzene, benzoic acid, ether and acetone were found to have a decided anticatalytic action but are not as effective as the substances previously mentioned. Acetic acid and carbon tetrachloride are almost without action, which proves that the preservative action is not due merely to the presence of a foreign substance.

Observations were made on the auto-oxidation of two other substances closely related to chloroform, namely, bromoform and methylene chloride.

The latter developed a decided, although very small amount of oxidizing substance after 10 weeks' standing. With bromoform the development of oxidizing substance and acid was rapid at first but it soon reached a maximum which was not large.

#### Summary

Chloroform undergoes auto-oxidation in diffused light with the formation of a peroxide, which is very probably dichloro-carbon-peroxide. This substance is formed at a gradually increasing rate and its accumulation proceeds up to a certain point, where rapid decomposition sets in. Beyond this point the oxidation of the chloroform continues, although very little peroxide is found in the solution.

The phosgene, carbon dioxide, chlorine and hydrochloric acid present in the oxidized product result from decomposition and hydrolysis of the peroxide.

The preservative plays the role of an anticatalyst.

#### NOTES

The Molecular Conductivity of Potassium Iodide in Epichlorohydrin.— Epichlorohydrin¹ was treated with anhydrous copper sulfate for a few days and the product distilled. It had a constant boiling point of  $115^{\circ}$ . After a second distillation the distillate was colorless and had a constant conductance of  $0.2 \times 10^{-7}$ . This could not be changed after repeated treatment and distillation. The potassium iodide used was known to have been of very high purity.

The solubility of potassium iodide in this solvent was first found by a preliminary experiment. It was found that a gram molecule in 60 liters would give just the convenient solution. Therefore, 0.0277 g. of potassium iodide was dissolved in 10 cc. of epichlorohydrin and the conductance was found by the well-known Kohlrausch method. Every necessary precaution was taken and the conductivity cell was kept in a thermostat at a constant temperature of 18.00°. The value of the cell constant at that temperature was found to be 0.260.

The Points of Minimum Swelling of Ash-Free Gelatin. —In an earlier paper² we described experiments indicating two points of minimum in the curve showing the degree of swelling of gelatin as a function of Sörensen (PH) value, one at 4.7 and the other at 7.7. This finding was criticized

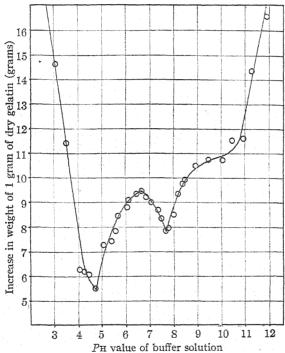

Fig. 1.—The two points of minimum swelling of ash-free gelatin.

by Sheppard and Elliott³ on the ground that the gelatin used was not ashfree. It was intimated that the point of minimum found at 7.7 was probably due to mineral impurities in the gelatin used.

- ¹ Presented before the Leather and Gelatin Division at the 66th meeting of the American Chemical Society, Milwaukee, Wis., September 12, 1923.
  - ² Wilson and Kern, This Journal, 44, 2633 (1922).
- ³ Paper presented before the 65th meeting of the American Chemical Society, New Haven, Conn., April 6, 1923.

Through the kindness of Dr. Sheppard, we secured a sample of Eastman's highly purified gelatin, which proved to be practically ash-free and gave a Sörensen value of 4.7 in distilled water. We repeated the experiments exactly as described in the earlier paper, except for using a more dilute buffer solution so as to increase the sensitivity of the measurements. In all cases, the buffer solutions had a final concentration of 0.02 M phosphoric acid plus sodium hydroxide to give the desired Sörensen value. The results obtained, at  $7^{\circ}$ , are shown in Fig. 1.

The second point of minimum, at 7.7, stands out too sharply to be attributed to experimental error and we found that the results can easily be duplicated. Moreover, Mathews and Higley⁵ studied the absorption spectrum of gelatin with changing Sörensen value and found minimum values for the wave length of maximum absorption in the ultraviolet at PH 4.68 and 7.66, coinciding with our points of minimum swelling. Since they used gelatin solutions, it was not necessary to use an extraneous buffer material. It is important to note that they used purified gelatin and regulated the Sörensen value by the simple addition of hydrochloric acid or sodium hydroxide.

That the two points of minimum have a real existence seems established, although the explanations offered as to the cause still remain in the controversial stage.

Konstanten der Atomphysik (The Constants of Atomic Physics). By Dr. Walther A. Roth and Dr. Karl Scheel. Julius Springer, Linkstr. 23–24, Berlin, W. 9, 1923. 114 pp. 9 figs. 27.5 × 19.5 cm. Price \$2.00.

This is a separate printing of 32 tables (114 pp.) from the new fifth edition of "Landolt-Börnstein." As such it needs no introduction to the scientific public except to say that the same high level of thoroughness and accuracy has been maintained as in previous editions. The data purport to be complete to the end of 1921, and the many specialists who have made the selection seem to have done their work well. The German

Commission's atomic weights are used, "Avogadro's number" is called Loschmidt's, and other "scars of war" are apparent, but as a whole one feels only admiration for the achievement of such a task under the difficulties which must have beset it. The tables include among other things radioactive constants, ages of minerals, molecular magnitudes, selected wave lengths from all types of spectra, crystal structures, and many kinds of data concerning radiation. Some defective type has been used on p. 4, and at the top of Table 6, "8a," should read "6a."

NORRIS F. HALL

Fluorescenz und Phosphorescenz im Lichte der Neueren Atomtheorie (Fluorescence and Phosphorescence in the Light of the Modern Atomic Theory). By Peter Pringsheim. Second Edition, revised. Julius Springer, Berlin, 1923. viii + 228 pp. 33 figs. 22 × 14 cm.

The first edition of this excellent little monograph has been reviewed in This Journal, 44, 1602 (1922). The addition of 60 references has again brought the bibliography up to date. The text has been revised and amplified throughout to bring it into conformity with the most recent conclusions of research. Consequently a number of provisional statements in the first edition now reappear as definite and dependable conclusions. The advantages of such a revision, though it has expanded the book by only 20 pages, need not be further emphasized. It is to be hoped that the author will be able to continue this policy in later editions.

G. S. FORBES

Grundriss der Photochemie in elementarer Darstellung als Einführung in das Studium (Outline of Photochemistry, in Elementary Presentation, as Introduction to the Subject).—By Prof. Dr. J. PLOTNIKOW, Professor and Director of the Physicochemical Institute at the Royal Technical Hochschule at Agram. Walter de Gruyter and Company, Berlin and Leipzig, 1923. vi + 196 pp. 34 figs. 23 × 15 cm. Price \$1.00.

The misfortunes of the author between 1917 and 1920 due to political and economic convulsions in Russia and surrounding countries have been recounted in a review of "Allgemeine Photochemie," This Journal, 43, 2260 (1921). Later he received news that "the exponents of the new civilization" in Russia had converted into cigarette wrappers the manuscript of his "Photochemisches Praktikum" which, ready for the press, had been stored in Moscow. Accepting a call to Agram with high hopes of resuming experimental research, he found the laboratory appropriated for other purposes. His inextinguishable creative impulse then found expression in the present work, which he describes as a summary of his previous books, but in elementary form, intelligible to all desiring to follow the newer developments of natural science.

The beginnings of photochemistry among the ancients and its progress down to recent times interest the author more than the theorizing of the last ten years. The Bohr atom and Einstein's photo-equivalence are indeed more adequately treated than in "Allgemeine Photochemie." The author, however, frankly distrusts these as a foundation for photochemical theory. The complete omission of various hypotheses and theories which have recently been the subject of much discussion may have seemed necessary in view of the permissible size of the book and in view of the audience for which it is intended. Plotnikow's own well-known convictions regarding photochemical valence, kinetics, and temperature coefficients are developed at some length. The present divergence of opinion with regard to such matters might have been more distinctly stated. Examples and applications of photochemical action are given in quantity and variety sufficient to whet the reader's appetite for wider information along these lines. Considering the author's thorough knowledge of photochemical technique and his important contributions towards its improvement, an exposition in greater detail would have been welcome.

The author brought to his task the resources of a lifetime of experimental research, technical experience and deductive thought in this domain of science. He has triumphed over crushing anxieties and disappointments, and has produced a highly readable and instructive book which meets a real need in chemical pedagogy. For him, moreover, photochemistry is a passion as well as a problem, and his enthusiasm must infect the most casual reader.

G. S. Forbes

The Determination of Hydrogen Ions. An elementary treatise on the hydrogen electrode, indicator and supplementary methods with an indexed bibliography on applications. By W. Mansfield Clark, Ph.D., Professor of Chemistry, Hygienic Laboratory, United States Public Health Service. Williams and Wilkins Company, Baltimore, U. S. A. Second edition, reprinted, June, 1923. 480 pp. 42 figs. 23.5 × 15.5 cm. Price net, postpaid, \$5.00, United States, Canada, Mexico, Cuba; \$5.50, other countries.

This second edition gives a detailed exposition of "the two methods which are in use daily by workers in several distinct branches of biological science." Colorimetric methods and the electrometric method for measuring hydrogen-ion concentrations and various forms of apparatus are described fully. Sufficient theory is presented to give the experimenter a good understanding of the meaning of his results. Supplementary methods are also briefly reviewed, with references, and an extensive bibliography on methods and applications of hydrogen-ion determinations is given.

Some of the chapters of the first edition have been rewritten and all have been brought up to date, resulting in a work of 480 pages as compared with 312 pages in the original issue. A number of additions are worthy of special mention. A long list of indicators with their colors and ranges of usefulness has been added. The chapter on approximate indicator

methods has been greatly expanded. An elementary description of the potentiometric method for measuring electromotive forces has been added to the description of the electrometric method with more or less repetition in a later chapter. However, according to the footnote on p. 149, this matter needs emphasis. Descriptions of the ballistic galvanometer and electrontube methods of measuring electromotive forces have been added. The chapter on reduction potentials has been considerably extended and interesting relationships between the hydrogen electrode, metal electrodes in solutions of metal ions, and oxidation-reduction electrodes are pointed out. A description of the quinhydrone method brings the chapter on supplementary methods up to date. Over 900 references have been added to the bibliography, making a total of more than 2,000 references on hydrogen-ion methods and their applications in various branches of science.

In the chapter on standardization of measurements of Sörensen values  $(P\mathrm{H})$  the author points out that the electrometric method measures only ratios between concentrations, so that for the calculation of  $P\mathrm{H}$  values a determination of one concentration by an independent method is required. Sörensen assumed that conductance data gave the correct degree of dissociation for 0.1~M hydrochloric acid solution and based his  $P\mathrm{H}$  values on that. Recent work on activities has shown that Sörensen's assumption was undoubtedly in error, but in the meantime a vast amount of hydrogen-ion data has been accumulated in which Sörensen's value for the 0.1~N calomel electrode has been accepted. In view of the still unsettled state of the newer conceptions of electrolytic dissociation and the possibility of further changes, and also in view of the large amount of data based on Sörensen's value for the calomel electrode, the author wisely recommends that Sörensen's value continue to be used for the present.

A few minor points where improvement could be made seemed worthy of mention. Some of the tables lack titles, notably Table 3. The first paragraph in small type on p. 44 seems out of place. The sections on the theory of concentration cells, pp. 144 and 154, should contain some mention of the liquid-junction potential difference, which is neglected in the treatment. The statement that no important chain can be constructed without involving liquid-junction potentials (p. 163) is too general.

This is a complete and useful book and should be in the hands of all who work on hydrogen-ion concentrations. That it fills a need is evidenced by the exhaustion of the reprint of the first edition and the second edition.

WARREN C. VOSBURGH AND MARION EPPLEY

Oxidations and Reductions in the Animal Body. By H. D. Dakin. Second edition. Longmans, Green and Co. New York, London, Toronto, Bombay, Calcutta and Madras, 1922. ix + 176 pp. 24 × 16 cm. Price \$2.00 net.

Ten years have elapsed since the first edition of this Monograph appeared. For the most part, the addition of new experimental data and oc-

casional alterations in opinion are all that has been attempted in revising it, but the chapter on The Carbohydrates—the one most affected by progress made in the ten-year period—has been to a large extent recast. It is of interest that the new matter of this chapter deals chiefly with the earlier steps in the cleavage of glucose, before oxidation has become involved at all, for this seems to show that Dakin has already begun a task which, in his preface, he sets himself for the future. There he says: "It has become increasingly clear in recent years that the oxidations and reductions occurring in the living body are so closely interwoven with other types of reaction, especially condensation and hydrolysis, that it would seem that their consideration apart from other metabolic changes was becoming unduly artificial and could not be justified much longer." A section on the formation of sugar from fatty acids, and a few others not to be found in the original edition, also bear witness to the same tendency.

In the beginning, the author undertook to treat his subject almost wholly from the standpoint of the fate of organic compounds in the animal body, and little attention was paid to the mechanism of their oxidation or reduction. The space devoted to this question has now been about doubled; Wieland's dehydrogenation theory receives particular attention, and this and other developments relating to the participation of water in oxidation-reduction processes lead finally to an account of the remarkable catalyst (glutathione) recently discovered by Hopkins in animal and plant tissues.

The book will continue to be a mine of ready information to those interested in this field. It is to be hoped that the author can now find time to revise it at more frequent intervals, for no other publication covers the same ground.

CYRUS H. FISKE

Chemie der Pflanzenzelle (The Chemistry of the Plant Cell). By Dr. Viktor Grafe, Professor of the Biochemistry of Plants at the University of Vienna. Gebrüder Borntraeger, Berlin, 1922. viii + 420 pp. 32 figs. 25.5 × 16.5 cm.

In this book the physiology of plants is treated from the point of view of the energy transformation involved, with the structural and chemical aspects of the subject as a background. There are three portions, the first of which includes a descriptive treatment of such fundamental physicochemical processes as osmotic pressure, interfacial tension, and colloidal behavior; the second section treats of the structure of plants and the chemistry of their components, including enzymes, pigments and toxins; and the third and largest section deals with the dynamic chemistry of plants, particularly as displayed in the processes of photosynthesis and the perception of and response to stimulus.

The first section is the least satisfactory: the explanations are often cumbersome and the examples poorly chosen; it is often difficult to under-

stand the author's meaning. The chapters on stimulation and response show the author at his best.

The book as a whole is poorly organized, and reflects by its errors of citation and its neglect of recent important researches the author's lack of foreign periodicals. The author displays a not unusual fault in being hypercritical of theories which cannot conveniently be reconciled with those which he himself supports.

All life processes are considered first of all as transformations of energy; every theory to be acceptable to the author must account satisfactorily for the intake, storage or release, and outgo of energy. This alone makes the book unusually suggestive; the treatment of photosynthesis, and of stimulus and response is well worth a thoughtful perusal, even though the reader may remain unconvinced or even at times doubtful of the real meaning. Another striking feature of the book is the constant invocation of vaguely defined surface phenomena as explanations of vital phenomena.

The author does not successfully generalize his conclusions; in fact, he seems to despair of the ultimate solution of many problems. The book will appeal to those who insist upon meticulous observance of detail; those who ruthlessly demand clear and concise generalizations will hardly be satisfied.

S. C. Brooks

Practical Bacteriology for Chemical Students. By David Ellis, Ph.D., D.Sc., Head of the Department of Bacteriology and Botany in the Royal Technical College, Glasgow. Longmans, Green and Company, 55 Fifth Avenue, New York; 39 Paternoster Row, London, E. C. 4; Toronto, Bombay, Calcutta and Madras, 1923. viii + 136 pp. 55 figs. 19.5 × 13 cm. Price \$1.50.

David Ellis, the author, is already known to American workers in the field of bacteriology through the medium of his textbook, "The Outlines of Bacteriology," and a later work, "The Iron Bacteria." He has also contributed numerous monographs on the subject of the iron bacteria which have special interest for the waterworks biologist and engineer. In all of these he has shown an ability to present fundamental information in an effective way.

His reason for compiling the little volume which is here reviewed is that "in the study of Chemistry there are many avenues of research which are closed to the intending investigator owing to a lack of knowledge of the elementary principles of bacteriology." If the book is an aid to overcoming this deficiency, it is a real contribution to scientific literature. It is the judgment of the reviewer that the book does this and that it will appeal most strongly to the class it seeks to reach.

There are twelve chapters of about equal length, each of which takes the form of a series of laboratory exercises designed to acquaint the beginner with fundamental principles and procedures in bacteriology and to familiarize him with the working tools of the science. Discussion of the subject matter of chapters and explanation of results are interspersed with the exercises. The latter are clearly set apart, each step is numerically indicated, formulas are given for solutions and examples presented for the calculation of results. There are 55 figures, most of which are conventionalized drawings designed to set forth essential details. The book is a manual of elementary procedures amplified by the minimum of discussion and designed to serve as a guide to the acquisition of more complete knowledge.

The first eight chapters deal with such subjects as bacteriological apparatus, culture media and their use, staining, morphological and physiological characteristics of bacteria, biochemical activities and methods of isolation and numerical estimation. The ninth and tenth chapters deal with the examination of water and sewage. Usual procedures are given and also confirmatory tests for *Bact. coli communis*. The latter do not include some of the more recent tests which have largely supplanted, at least in this country, the older tests and which give a far better idea of the fecal or non-fecal origin of colon forms. Methods for the identification of *Bact. enteritidis sporogenes* are also given in detail. The two concluding chapters deal with yeasts and moulds. The novitiate in the science will find a great deal in these chapters which will acquaint him with the principal types of these organisms, methods for their culture and their biochemical reactions.

There are certain omissions in information which, if added, would not greatly increase the size of the book and would add considerably to its value.

A short description of the microscope would be of great value to many students of chemistry. The writer has found that a great number of such students are entirely unfamiliar with this delicate instrument which is so invaluable in many branches of science. The different morphological groups of bacteria could well have been described to acquaint the new student with the exterior appearance of these cells as seen under the microscope.

No mention is made of the adjustment of culture media reaction by means of hydrogen-ion determinations, nor of the use of hydrogen-ion concentration in determinations of acidity of cultures. This practice has almost displaced former titration methods, which deserve mention only as secondary procedures.

The book as a whole merits approval from the standpoint of what it purports to be. Many of the exercises will provide teachers as well as students with suggestions for laboratory work.

Rhus Dermatitis from Rhus Toxicodendron, Radicans and Diversiloba (Poison Ivy). Its Pathology and Chemotherapy. By James B. McNair. University of Chicago Press, Chicago, Illinois, 1923, xi + 298 pp. 18 figs.  $23.5 \times 5$  cm. Price \$4.15 postpaid

With the exception of Chapter XII, the remaining fifteen chapters of this book represent a collection of reprints of papers previously published by the author in various botanical and medical journals. The guiding aim is to establish a scientific basis for the treatment of dermatitis produced by the poisonous constituents of the rhus species (poison ivy, poison oak, etc.). It is stated in the preface that "The investigation of this poison has been carried on from the standpoint of pharmacology, of botany and of chemistry." The botanical and pharmacognostic features are considered in the first eight chapters, which abound in historical reviews and summaries of the literature. The original work along botanical lines is found in these chapters and appears to be sound. Probably the best part of the book is in Chapter X, which deals with the "Chemistry of the Poisonous Principle." This is claimed to be a polyhydric phenol, named by the author "lobinol" (from Rhus diversiloba or poison oak). It is not a definite chemical substance, but appears to be a vellowish-brown, viscous (oily?) residue (p. 93, analytical scheme) with phenolic properties, and neither a protein nor a glucoside. It may be a mixture, similar to or identical with toxicodendrol, the oily constituent of Rhus toxicodendron (poison ivy), first described by Pfaff. Hence, the reader is left in doubt as to the real identity of the constituent, and as to the justification of coining a new name ("lobinol") for it.

Chapter XIV deals with immunity to the poison and consists almost entirely of a review of the literature. The author argues against the production of immunity by the administration of the poison, but is of the opinion that natural immunity exists against it, though this is usually relative and seldom absolute.

Coming to Chapters XV and XVI, which deal with remedies for and treatment of the dermatitis, disclosure of the rational remedy would be expected, for the author states in the preface "Botany and pathology combined with a chemical knowledge of the structure of the poison have yielded a rational remedy for Rhus dermatitis." However, this is not the case, and for the following reasons: (1) The structure and nature of the poison remain unsolved. (2) Erroneous speculations in pharmacology cannot furnish the basis of a rational treatment. For instance, it is stated on pp. 113–114 that "The erythrocytes contribute hemoglobin the iron of which has the power to combine with lobinol. Likewise the blood brings glucose which on its conversion into glucuronic acid, probably has power to combine with the noxious properties of lobinol." Similar ideas are reiterated on p. 176. Moreover, if it is true that "There is reason to

believe that Rhus poison is not transmitted by body fluids....." (p. 114), these speculations could have been omitted. (3) Out of a long list of therapeutic agents and trials, the most suitable remedy settled upon by the author is a lotion containing ferric chloride. This is not new. Metallic salts (lead acetate, etc.) are well known to be effective precipitants of the poison and useful in treatment of the dermatitis. (4) The remaining measures and adjuncts in the treatment proposed by the author are familiar and largely empirical, inclusive of the paraffin treatment, which had been exploited during the World War for severe skin burns from flame projectors, etc.

From what is known of skin irritants ("dermitant," used by the author presumably means the same) in general, including war compounds, etc., the designation of rhus dermatitis as a "specific disease" is not justified. The use of the heading, "Chemotherapy....," for the various and mixed treatments outlined in Chapter XVI is not in accordance with the accepted meaning of the term.

On the whole, this book will furnish interesting and profitable reading for the general reader. However, for the physician and investigator the inclusion of considerable irrelevant and redundant material reduces its usefulness. This exists on pp. 109, 110, 122, 132, 138, 142, 144, 146, in most of Chapter XV which contains a six-page list of remedies, most of which are obsolete, and among the 34 pages of "abstracts," really detailed descriptions, of clinical case histories in the Appendix. In the Appendix there are 77 pages of a systematized bibliography pertaining to rhus and other matters, a good part of which will be useful to future students of the subject. In view of the great difficulties of investigating skin irritants and the practical nature of the problem of rhus dermatitis, the efforts and aim of the author are laudable. However, it may be doubted if our knowledge of rhus dermatitis has been advanced since the work of Pfaff in 1897.

# Subject Index to Volume XLV, 1923'

ABIETIC acid	0
Acetals, p-bromoacetaldehyde and monobromcacetaldehyde—their prepn., preper-	9
ties and utilization for the synthesis of bromo- and hydroxy-cyclic, related to	
polysaccharides, 734; catalytic synthesis of the, and their halogenation, 1552;	
action of Grignard reagent on, 1807; use of C ₂ H ₂ for synthesis of cyclic, 3108;	
5-, 6-", and 7-membered cyclic, and attempts to prepare cyclic, contg. more than	
7 ring atoms	
Acetamide, soly relations of	-
2-Acetamido-5-bromo-p-xylene	9
Acetanilide, soly. relations of	6
Acetic acid, hydration of, 702; detn. in acetic anhydride	9
Acetic anhydride, catalytic decompn. of formic acid in, 455; ring closure of hydrazo-	
dithio- and -monothio-dicarbonamides with, 1036; detn. of AcOH in 268	9
Acetodiethylmethylmercuric chloride	9
Acetodimethylmethylmercuric chloride	0
Acetone, ternary system, toluene-water-, 2555; decompn. of	9
Acetophenone-p-arsonic acid	
Acetophenone dimethylacetal	3
Acetophenone o-tolil	0
Acetoxime, prepn. of	
o-Acetoxybenzylacetamide	
$\alpha$ -Acetoxymercuri- $\beta$ -alkoxy- $\beta$ -phenylpropiophenone, reaction with acids and with	•
KI	Q.
α-Acetoxymercuri-β-ethoxy-β-phenylpropiophenone	
$\alpha$ -Acetoxymercuri- $\beta$ -methoxy- $\beta$ -phenyl- $\beta$ -chloropropiophenone. 276	
α-Acetoxymercuri-β-methoxy-β-phenylpropiophenone	
1-Acetoxymercurimethyl-1,2-dihydrobenzofurans, conversion into the correspond-	J
	0
5-Acetoxymercuri-3-nitrosalicylaldehyde	
Acetyl-m-aminobenzoic acid, NH ₄ salt of	
Acetyl-p-aminobenzoic acid, NH ₄ salt of	U
2-Acetylamino-4,6-dibromo-5-methylphenol, and acetate and action of benzoyl	
chloride47	4
Acetylchloroaminobenzene, photochem. study of, 2574; formation of p-chloro-	
acetanilide from	1
Acetylene, prepn. of oxalic acid from, 795; catalytic condensation with C ₆ H ₆ and	
its homologs, 3090; use for the synthesis of cyclic acetals, 3108; partition be-	
tween ethylene glycol and trimethylene glycol, etc., 3122, 3123; partition be-	
tween ethylene glycol and 1,4-tetramethylene glycol	
3-Acetyl-6-methoxybenzonitrile	
o-Acetyloxybenzylbenzamide, hydrolysis of	3
Acetyl radical, effect of relative positions of hydroxyl and amino radicals in the	
migration of, from N to O	9
Acids, adsorption by activated sugar charcoal, 1109; adsorption of substituted	
org., by activated sugar charcoal, 1112; hydrogen-ion catalysis by, 2813, 2815;	
neutral NH4 salts of some org., and their substituted derivs	19
er <u>ak dara kanala</u> n di Siring Bertaga di Tibiran kanalan bertaga kenalah di kanalan di kanalan di Kanalan bertaga	

¹ This index was prepared in the Editorial Offices of Chemical Abstracts through the courtesy of Dr. E. J. Crane and under his direction.

Actinium emanation, solubilities of	690
Additions	3140
Adrenaline, derivs. of synthetic	1792
Adsorption, of toluene vapor on plane glass surfaces, 63; lecture expt. demonstrat-	
ing, 437; of gases by oxide catalysts, 887; and catalysis in CO oxidation, 900;	
influence of temp., pressure and supporting material for the catalyst on the,	
of gases by Ni, 920; by activated sugar charcoal, 1106; isotherms in catalytic	
combination of C ₂ H ₄ and H in the presence of metallic Cu, 1196; of gases by	
Cu, 2296; of mixed gases by charcoal—CO ₂ and N ₂ O	
Alchemy, of Geber (book rev.)	1341
Alcohols, urethans from Cl-substituted secondary and tertiary, 475; interaction	
of aliphatic, and $\beta$ - $\gamma$ -dibromopropyl isothiocyanate, 482, 3142; reaction with	
bromomethylphthalimide and its use for the sepn. and identification of, 541;	
action of bromomethylphthalimide on, contg. water, 543; purification and some	
phys. properties of certain aliphatic, 1334, 3140; ionization of	1348
Aldehydes, reduction of, 1071; mechanism underlying the reaction between, and	
tautomeric substances of the keto-enol type, 1975; simplification of the Gatter-	
mann synthesis of hydroxy, 2373; condensations of, with resorcinol and some	
other aromatic hydroxy compds., 2984; condensation to esters by Al ethoxide.	3013
Aldoses, revision of Rosanoff's diagram of the	1273
Alkali, action on substituted uric acids	3056
Alkali metal hydroxides, action of solns. of, on Cu oxide and on Cu	
Alkali metal perchlorates	
Alkali metals, at. vols. of halogens and, in combination, 423; diams. of atoms of,	
424; action on triphenylmethyl and its compds	
Alkaline earth perchlorates	286
Alkoxychlorophosphines, addn. to carbonyl compds	762
Alkylguanidines, prepn. of	1755
Alkyloxytriphenylmethyl	190
Alkyl tin halides, compds. formed between, and NH3 and the amines	3078
Allophanic acid, γ-chloropropyl ester	726
Allotropy, Theory of (Smits, book rev.)	2472
Allyl acetone chlorohydrin	2438
Allyl corn starch	2701
Allyldextrin	2700
Allyl ethers, of various carbohydrates	2698
3-Allyl-4-hydroxycinnamic acid, and Me ester	1853
Allylinulin	2701
4-Allyloxycinnamic acid, Me ester	1853
Allyl potato starch	2701
9-Allylpseudouric acid.	144
9-Allyluric acid	144
Alumina, reactions of formic acid at the surface of—selective activation of	809
Aluminum, sepn. from Mn and certain other elements, 676; displacement of metals	
from solus. of their salts by less electropositive elements—replacement of Na	
and K by Mg and, 2788; diffusion of H through	
Aluminum ethoxide, condensation of aldehydes to esters by	
Amalgams, heat of soln. of Tl in dil. Tl	
Amines, identification of, 2696; compds. formed between alkyl tin halides and	3078
Amino acids, detn. of, of feeds—of linseed meal, wheat bran, soy beans and red clover	
hay, 815; effect in retarding the hydrolytic decompn. of an enzyme, 1960; oc-	
currence of free, in the ungerminated wheat kernel, 2137; arsenated N-aryl.	2751

Aminoarylarsonic acids, condensation with pyruvic acid and aldehydes	1313
Aminobenzoic acids, decompn. by boiling water	751
2-Amino-5-bromo-p-xylene, hydrobromide	2000
2-Amino-4-chlorobenzamide	1027
2-Amino-4-chlorobenzoic acid.	1027
p-Amino-o-chlorophenol	2193
6-Aminochromane, and derivs	
m-Aminomandelic acid, resolution of	
3-Amino-4-methoxyacetophenone	
m-Aminophenol, ethers of	528
p-Aminophenol, action of Br and HNO3 on	481
m-Aminophenyl allyl ether	539
p-Aminophenyl β-bromoethyl ether	539
$m$ -Aminophenyl $\gamma$ -bromopropyl ether	537
γ-Aminopropanols, substituted	790
Amino radical, effect of relative positions of hydroxyl radical and, in the migration	
of acetyl from N to O	469
d-cis-3-Amino-1,2,2-trimethylcyclopentanoic acid, deaminization of Me ester of	
2-Amino-p-xylene, bromination of, and certain new azo dyes	1999
Ammino compounds, equilibria between the acido- and aquo-Ir pentammines,	1000
378; soly. of Co NH ₃ salts in Na ₂ SO ₄ and NaCl solns	2006
Ammonia, reactions of strongly electropositive metals with org. substances in	2000
liquid, soln., 768, 779, 1780, 2756; apparent deviation from Henry's law for	
the system, $-H_2O$ , 915; synthesis in the low-voltage arc, 1605; resistance-	
temp. coeff. of concd. solns. of K in liquid, and the sp. conductance of solns.	
of K in liquid, at intermediate concns., 2551; action on Ca and Ba nitrides,	
2559; equil., 2918; compds. formed between alkyl tin halides and	2079
Ammonium cuprous carbonate, absorption of CO by, solns	
Ammonium cuprous formate, absorption of CO by, solns	
Ammonium perchlorate	286
	200
Ammonium salts, reaction between Br and, and its effect on the pptn. of MnO ₂ ,	2000
1883; neutral, of some org. acids and their substituted derivs	2010
Amylase, effect of amino acids in retarding the hydrolytic decompn. of pancreatic.	
Amylene, action of SeOCl ₂ on.  tert-Amyl mercuric bromide.	
	822
Amylurea.	1919
Analysis, qual., of the Fe group, 438; Pharmaceutical and Food, (Thurston, book	
rev.), 1089; use of bromate in vol., 1115, 1417, 1666, 3142; Lunge-Berl-	
Chemisch-technische Untersuchungsmethoden (Berl, book rev.), 1572;	
Calcus. of Quant. Chem., (Hamilton, Simpson, book rev.), 1573; Qual. Org.	0000
(Kamm, book rev.), 2006; Clinical Lab. Methods (Haden, book rev.)	
Anhydrocamphoronic acid	
Anhydrocamphoronyl chlorides	
Anhydro-α-hydroxymercuribenzoylacetic acid	
1-Anilidobenzothiazole	2590
Aniline, action of Br and HNO ₃ on, 482; trichloroacetate, 1996; antiseptic action	2100
of the ZnCl ₂ salt of	
Aniline black, action of Br and HNO ₃ on.	482
3-Anilino-4-carbethoxy-5-oxyisoxazole.	
2-Anilino-4-carbethoxy-5-oxypyrazole	1079
2-Anilino-3-chloro=5-hydroxy-1,4-naphthoquinone	1919

Animal organism, Oxidations and Reductions in the (Dakin, book rev.)	3145
4-Anisalhydantoin	848
p-Anisylbiphenylenemethyl peroxide	219
4-Anisylhydantoin	848
4-Anisylhydantoin-3-propionic acid	, 852
Anthraquinones, 1831; absorption spectra of	2445
Anthraquinone sulfonic acids, reactions with mercaptans	1831
β-meso-Anthroylacrylic acid, and Me ester	
Antimonous oxides, cryst. structure of the cubic forms of	1621
Antimony, at. wt. of, 570; system, Pb-, 1683; at. wt. of, from diff. sources, 2009;	
action of SeOCl ₂ on	
Antiseptics, action of the ZnCl ₂ salt of aniline	
Apatite, relative detn. of the at. wt. of Cl in Bamle	1577
Arachidic acid, detn. of the mixt. of, and lignoceric acid in peanut oil	113
Aroxychlorophosphines, addn. to carbonyl compds	762
Arsenic, sepn. of Sn and, 1187; detection of minute amts. of, in GeO ₂	1380
Arsenic compounds, arsenated benzophenone and its derivs., 510; arsenated benz-	
anilide and its derivs., 757; detn. of C and H in org., 998; derivs. of phenyl-	
diketopyrrolidine, 1307; arsenated N-arylamino alcs., 2751; aliphatic arseno	
compds	
Arsenious oxide, certain phys. properties of, in water soln., 1102; cryst. structure of	
the cubic forms of	
Arsenious sulfide, action of light on, hydrosol, 16; sols	
Arsenoacetic acid	
2-p-Arsenoanilinoethanol	
3-p-Arsenoanilinopropanol	
p-Arsenobenzovlanilide	
p-Arsenobenzoyl-p-anisidide	
p-Arsenobenzoylanthranilide	760
p-Arsenobenzovl-α-naphthylamide	760
p-Arsenobenzoyl-p-phenetidide	760
p-Arsenobenzoyl-p-xylidide	760
Arsonation, of o- and m-cresol, 800; of phenol	
2-p-Arsonoanilinoethanol	
3-p-Arsonoanilinopropanol	
Arsonoarylamino alcohols	
Arsonoarylaminoethanols	
Arsonoarylaminopropanols	
p-Arsonobenzoylanilide	
p-Arsonobenzoyl-o-anisidide	
p-Arsonobenzoyl-p-anisidide	759
p-Arsonobenzoylanthranilide	759
p-Arsonobenzoylarsanilide	759
p-Arsonobenzoyl-p-phenetidide	
1-(4'-Arsono-3'-methoxyphenyl)-2-phenyl-4,5-diketopyrrolidine	1314
1-(4'-Arsono-3'-methylphenyl)-2-phenyl-4,5-diketopyrrolidine	1314
1-(4'-Arsonophenyl)-2-(4'-chlorophenyl)-4,5-diketopyrrolidine	1314
p-Arsonophenyl-β-hydroxyethyl nitrosamine	3105
p-Arsonophenyl-γ-hydroxypropyl nitrosamine	1305
1-(4'-Arsonophenyl)-2-(2'-methoxyphenyl)-4,5-diketopyrrolidine	1313
1-(4'-Arsonophenyl)-2-(4'-methoxyphenyl)-4,5-diketopyrrolidine	1313
1-(4'-Arsonophenyl)-2-(3',4'-methylenedioxyphenyl)-4.5-diketopyrrolidine	1314

3-o-Arsonophenyl-2-oxazolidone	3104
3-p-Arsonophenyl-2-oxazolidone	3103
3-p-Arsonophenyl-1,3,2-oxazone	3104
1-(4'-Arsonophenyl)-2-phenyl-4,5-diketopyrrolidine	1313
p-Arsonosobenzoylarsanilide, hydrated	759
Arsphenamine, S content of, and its relation to the mode of synthesis and the	
	2182
The state of the s	2754
β-Arylaminoethanols	785
$\gamma$ -Arylaminopropanols	794
Arylmonothioamides, action of hydroxylamine and of hydrazine on, of carbethoxy-	
ethylmalonate	3092
Atomic weights, 29th Ann. Rept. of the Comm. on	563
Atoms, structure of C ₆ H ₆ , 264; compressibility, internal pressure and magnitude	
of, 422; At. Form with Special Reference to the Configuration of the C Atom	
(Price, book rev.), 1858; photographing the disintegration of, 2095; Kon-	
stanten der Atomphysik (Roth, Scheel, book rev.), 2142; heat of ionization	
and structure of, 2805; Fluorescenz und Phosphorescenz im Lichte der	
Neueren Atomtheorie (Pringsheim, book rev.)	
Azido-carbondisulfide, formation, prepn. and general properties	2541
Azido-dithiocarbonic acid, formation, prepn. and properties	2604
Azobenzene, 1785; reduction of	1786
Azobenzene p-isothiocyanate, reduction of	
m-Azodimethylanilinemandelic acid	
p-Azodimethylanilinemandelic acid	1993
d- $m$ -Azo- $β$ -naphtholmandelic acid	
$l$ - $m$ -Azo- $\beta$ -naphtholmandelic acid	
$p$ -Azo- $\beta$ -naphtholmandelic acid	
m-Azophenolmandelic acid	
m-Azoresorcinolmandelic acid	
p-Azoresorcinolmandelic acid	
Azoxybenzene, 1785; reduction of	
Azulene, expts. on	717
BACILLUS, tuberculosis, sugar contd. in the nucleic acid of	1000
Bacteriology, Practical, for Chem. Students (Ellis, book rev.)	
	1539
Barbituric acid, new hypnotics of the, series.	243
Barium chloride, dissociation pressures of hydrates of, 349; effect of sucrose on	220
the activities of the ions of	1632
	2559
	2662
	1109
	1987
Benzalacetophenone, addn. of diphenoxychlorophosphine to, 767; addn. of mono-	1901
phenoxydichlorophosphine to	766
	1314
Benzalchromanone	
Benzaldehyde, 1083; addn. of phenoxydichlorophosphine, methoxydichlorophos-	
phine, and ethoxydichlorophosphine to, 765; equil. between benzoin and,	
836; action of aq. alkali on, 2356; addn. of benzoyl bromide to	2360
Benzalpinacoline, reduction products of	1557
mortismatramonitarial animananamic transfer on the existence of the existe	

Benzanilide, arsenated, and its derivs	757
Benzarsonic acid	757
Benzene, structure of, 264; rings through the $m$ and $p$ positions of, 528; soly.	
of water in, 1143; relation between mol. structure and odor in trisubstituted,	
2161; catalytic condensation of C ₂ H ₂ with, and its homologs	3090
Benzidine, structure of	521
Benzil, rearrangement, 1509, 1522, 1529, 2356; action of ultraviolet light on 1828,	1829
Benzilic acid, action of ultraviolet light on	1830
Benzilodicyanohydrin	1527
1,3-Benzodioxanes, aryl	2417
Benzoic acid, soly. relations of	
Benzoin, 1529; equil. between benzaldehyde and	836
Benzophenone, arsenated, and its derivs	510
Benzoquinones, effect of the solvents on the reduction potentials of certain	2194
Benzoylacrylic acid, isomeric esters of	
γ-Benzoyl-2-aminobutane	
2-Benzoylamino-4-6-dibromo-5-methylphenol, acetate	474
Benzoyl bromide, addn. to benzaldehyde	2360
Benzoylcarvomenthyl semicarbazide	
γ-Benzoyl-2-chloro-3-aminobutane	
γ-Benzoyl-1-chloro-2-butane	
Benzoylfenchyl semicarbazide	3004
Benzoylformic acid, and Me ester, 1979, 1980; mercurous and mercuric salts	
Benzoylhexahydrophenyl semicarbazide	
Benzoylisogranatolinecarboxylic acid, Et ester	
Benzoylmenthyl semicarbazide	
Benzoylmethylmercuric chloride	
1-Benzoyl-2-methyl-4-phenylpyrrolidine	
Benzoylnitrosocarvacrol, HNO3 addn. product	
Benzoylnitrosophenols	
Benzoylnitrosothymol, HNO2 addn. product of	
o-Benzoyloxybenzylacetamide	
o-Benzoyloxybenzylbenzamide	1742
Benzoylphenylnitrocyclopropane	
Benzylidene-o-arsanilic acid	1314
Benzylidene-p-arsanilic acid	1313

between ethylene and, 1014; luminous discharge in-possible detn. of the	
ionization potential of, 1192; catalytic decompn. of H ₂ O ₂ in a, -bromide soln.,	
1251, 2048; reaction between, and NH4 salts and its effect on the pptn. of	
$\mathrm{MnO}_2.$	1883
Bromoacetaldehyde, prepn., properties and utilization for the synthesis of acetals	
related to polysaccharides	734
2-Bromo-4-acetylamino-6-methylphenol, benzoate of	472
Bromoanhydrocamphoronyl chlorides	3076
3-p-Bromoanilino-4-carbethoxy-5-oxyisoxazole	
3-p-Bromoanilino-4-carbethoxy-5-oxypyrazole	
p-Bromobenzenesulfonamides.	
p-Bromobenzenesulfonyl chloride	
2-Bromo-4-benzoylamino-6-methylphenol and acetate.	
α-Bromo-n-butyric acid, NH ₄ salt of	
4-Bromo-1-cyanonaphthalene.	1112
p-Bromodiphenyl-1-naphthylcarbinol chloride	1778
p-Bromodiphenyl-1-naphthylmethyl peroxide	
α-Bromo-β-ethoxy-β-phenylpropiophenone	2767

Bromoethylidene bromohydrin	745	
Bromoethylidene glycerol	748	
Bromoethylidene glycol	. 747	
Bromoethylidenetrimethylene glycol	747	
α-Bromomercuri-β-ethoxy-β-phenylpropiophenone		
α-Bromomercuri-β-methoxy-β-phenylpropiophenone		
α-Bromo-β-methoxy-β-phenylpropiophenone, 2767; action of alkali on, addn. of		
mercuric acetate to the product, and reaction of ethylmagnesium bromide		
with	2769	
ω-Bromomethylfurfuraldehyde.	182	
	104	
Bromomethylphthalimide, reaction of ales, with, and its use for the sepn. and	~ 10	
identification of ales., 541; action on ales. contg. water	543	
4-Bromo-1-naphthalenecarboxylic acid and Et ester		
p-Bromophenylchrysofluorene		
p-Bromophenylhydrazodithiodicarbonamide		
m-Bromophenylmercuric acetate		
o-Bromophenylmercuric acetate		
p-Bromophenylmercuric acetate	1327	
p-Bromophenylmercuric chloride		
Bromopierin, reactions with chloropierin	2069	
β-Bromopropionic acid, NH ₄ salt of	3000	
Bromosaligenin	2419	
Bromotetraacetylfructose	2388	
p-Bromotriphenylcarbinol chloride		
p-Bromotriphenylmethyl peroxide		
1-(5-Bromo-2-p-xylylazo)-β-naphthol		
1-Butene, reaction with NCl ₃		
2-Butene, reaction with NCl ₂ .		
Butyl alcohol, reaction with $\beta$ - $\gamma$ -dibromopropyl isothiocyanate		
sec-Butyl alcohol		
1,5-Butylanthraquinonesulfone, sodium sulfonate.		
Butylanthraquinone thioether		
Butylene, action of SeOCl ₂ on		
sec-Butyl mercuric bromide.	821	
tert-Butyl mercuric bromide.	822	
	821	
sec-Butyl mercuric chloride	041	
CACODYL derivatives.	2996	
Cadmium, at. heat at low temps., 1413; heat of vaporization of, 2080; activities of	2000	
Zn, Sn, Pb, Bi and, in their binary liquid mixts	2885	
Cadmium cobaltinitrite.		
Cadmium sulfate, vapor pressures of hydrates of		
Calcite, non-existence of two forms of		
Calcium, equilibria in systems involving H, N and		
Calcium fluoride, surface energy of.		
Calcium hydride, action of N and H on, 2560; equil. in the system Ca-H, 2561;		
equil. in the system Ca, H, N, Ca nitride and, and reaction products	25/1	
Calcium hydroxide, electrometric study of the neutralization of $H_{a}PO_{4}$ by	881	
Calcium nitride, action of NH3 on, 2559; action of N and H on, 2560; equil. in the		
system Ca-N-, 2567; equil. in the system, H, N, Ca hydride and, and reac-	3.3	
tion products	2571	
Calcium oxide. See Lime.		

Calcium sulfate, soly. and surface energy of	
Calcium sulfite, heat capacity of dihydrate of, 2232; soly. of, dihydrate	
Calcium thiosulfate, sp. heat and free energy of diln. of solns. of	
Calculations, of Quant. Chem. Analysis (Hamilton, Simpson, book rev.)	
Calibration, of cells for conductance measurements	
Calorimeters	876
α-Camphoronamide-imide	
Camphoronic acid, derivs. of	
β-Camphoronimide, acid chloride of	
β-Camphoronimide-amide	3069
Camphor series, mol. rearrangements of the	
Cannizzaro's reaction	
Capsaicin, constitution of	
Capsicum, constitution of the pungent principle of	2179
Carbamic acid, trichloromethyldimethylcarbinol, trichloromethylphenylcarbinol	
and dichloromethyldimethylcarbinol esters of, 478; trichloromethylmethylcarbinol and 2-trichloromethyl-1,3-dioxolane-4-carbinol esters of	479
Carbanilic acid, $\gamma$ -chloropropyl esters, 726; $\gamma$ -chloropropyl-o-methyl ester, 727;	419
$\beta$ -chloroethyl esters, 787; trichloromethyldimethylcarbinol ester of	478
Carbanilidophenylhydroxyurea	
Carbethoxymalonic acid, action of hydroxylamine and of hydrazine on the aryl-	1200
monothioamides of Et ester of	3002
(3-Carboethoxypiperidino)acetic acid, and Et ester	
(3-Carboethoxypiperidino)propionic acid, Et ester	
Carbohydrates, action of dry HBr on, 176; effects of the method of desiccation on	
the, of plant tissue, 439; allyl ethers of various, 2698; reactions relating to,	
3108, 3117,	3124
Carbon, physicochem. study of the S held by, at high temps., 1; at. wt. of, 563;	
relative stability of the C-Hg linkage in dialkyl Hg compds., 820; detn. in org.	
compds. with As and with Hg, 998; At. Form with Special Reference to the	
· Configuration of the, Atom (Price book rev.)	1858
Carbon dioxide, system, CaO-, 1167, 3142; reduction by ultraviolet light, 1184;	
adsorption by charcoal	
Carbon disulfide, reaction on p-phenylenediamine	2349
Carbon monoxide, adsorption and catalysis in, oxidation, 900; catalytic oxidation	
of, 2305; MnO ₂ in the catalytic oxidation of, 2841; absorption by cuprous NH ₄	
carbonate and formate solns	3141
Carbonyl compounds, addn. of alkoxy- and aroxy-chlorophosphines to, 762;	10.57
reduction of	
o-Carboxyphenylarsonic acid	511
Carvomenthyl semicarbazide, and hydrochloride.	1342
Catalysis, decompn. of formic acid in acetic anhydride, 455; adsorption and, in	3000
CO oxidation, 900; decompn. of KClO ₄ and its, by Fe ₂ O ₃ , 1134; combination of	
$C_2H_4$ and H in the presence of metallic Cu, 1196, 2235; decompn. of $H_2O_2$ in	
a Br-bromide soln. and a study of the steady state, 1251; reduction of nitro	
compds., 1281; in Org. Chemistry (Sabatier, book rev.), 1859; Catalytic	
Action (Falk, book rev.) 2002; decompn. of H ₂ O ₂ in a Br-bromide soln.,	
2048; in oxidation of CO—efficiency of the catalysts, MnO ₂ , CuO and mixts.	
of these oxides, 2305; promoter action in the decompn. of KClO ₃ , 2330; de-	
compn. of H ₂ O ₂ by ferric salts, 2493; promoter action in homogeneous, 2512;	
in reduction of uracil to hydro-uracil, 2702; hydrogen-ion, by acids, 2813,	

2815; hydroxy ion, 2817; MnO ₂ in the catalytic oxidation of CO, 2841; condensation of C ₂ H ₂ with C ₆ H ₆ and its homologs, 3090; ion activities in homo-		
geneous	3141	
Catalysts, adsorption of gases by oxide, 887; influence of temp., pressure and supporting material for the, on the adsorption of gases by Ni, 920; Pt oxides as, in the reduction of org. compds.—activation by the salts of certain metals.		
1071; Pt oxide as, in the reduction of org. compds.—prepn. and properties of the oxide of Pt obtained by the fusion of chloroplatinic acid with NaNO ₃ ,		
2171; Pt oxide as, in the reduction of org. compds	3020	
Cataphoresis, of proteins.	954	
Cells, plant, Chemie der (Grafe, book rev.).		
Cells, voltaic, calibration of, for conductance measurements—intercomparison	0140	
of cell consts., 1366; design and use of conductance, for non-aq. solns., 1692;		
temp. coeffs. of unsatd. Weston cells	2268	
Cellulose, chemistry, 176, 734, 2433; mannose from white spruce, 1008; action		
of concd. HCl on diff., 1729; Lehrbuch der Cellulosechemie (Heuser, book rev.)		
2221; action of chloral on, 2363; allylated	2701	
Charcoal, adsorption by activated sugar, 1106; adsorption of mixed gases by	2638	
Chemical combination, possible reconciliation of the octet and positive-negative		
theories of	2959	
Chemical compounds, factors influencing, formation in fused salt mixts., 963;		
unsatn. and mol. compd. formation	1433	
Chemical constitution, relation between, and odor in trisubstituted benzenes,		
2161; relationship between the, of certain compds. and their effect upon the		
activity of urease	3142	
Chemicals, Org. Syntheses (Conant, et al., book rev.)	2005	
Chemical substances, Thermodynamics and the Free Energy of (Lewis, Randall,

m-Chlorophenylhydrazodithiodicarbonamide	1041
m-Chlorophenylmercuric acetate	1326
o-Chlorophenylmercuric acetate	1327
p-Chlorophenylmercuric acetate	1325
Chloropicrin, reactions with bromopicrin.	
γ-Chloropropyl aryl carbamates	792
β-Chloropropyl chlorocarbonate	725
$\gamma$ -Chloropropylurethans	723
Y-Chloropropylatemans	
Chromanone	
Chromic acid, partial and consecutive reactions in the photosensitive system:	2100
quinine sulfate, H ₂ SO ₄ and	1001
Chromolipoids (Palmer, book rev.)	
Cinnamalacetic acid, polymerization of allyl ester of	1342
Clay, relation of H-ion conen. to the flocculation of a colloidal, 1243; nature of the	1562
acidity of the colloidal, of acid soils	ogen
Clover, amino acids of, hay	2009
Clupanodonic acid	
	1290
Cobalt, sepn. of Fe and Al from, 676; detn. of, in the presence of metals of the Fe	
group, 1439; action of SeOCl ₂ on, 2093; interference of, in the bismuthate	0000
method for Mn	
Cobalt chloride, equil. in systems with HCl and H ₂ O	663
Cobalt compounds, soly. of Co NH ₃ salts in Na ₂ SO ₄ and NaCl solus	
Cobalt salts, complexes in solns. of	1353
Cobalt sulfate, dissociation pressures of hydrates of, 349; vapor pressures of hy-	to Pro / h
drates of	578
Coke, forms of S in	1
Collagen, hydrolysis by trypsin	1515
Collodion, membrane for liquid junctions.	1271
Colloids, action of light on As ₂ S ₃ hydrosol, 16; black colloidal suspension in P, 67;	
constitution of Fe ₂ O ₃ hydrosol, 297; heat of coagulation of Fe ₂ O ₃ hydrosol	
with Na ₂ SO ₄ , 311; Formation of (Svedberg, book rev.), 2004; mechanism of	
the mutual pptn. of certain hydrosols, 2532; detn. of size and distribution of	
size of particles	2910
Color, influence of S on the, of azo dyes, 2399; absorption spectrum and its relation-	
ship to	2420
Compressibility, internal pressure and at. magnitudes	422
Conductivity, electric, calibration of cells for conductance measurements, 1366;	
design and use of conductance cells for non-aq. solns., 1692; Injury, Recovery	
and Death in Relation to (Osterhout, book rev.), 1861; of dil. HCl, 2017; sp.,	
of solns. of K in liquid NH ₃ , 2551; equiv. conductance of Me ₃ SnCl in EtOH,	
2624 of Me SuCl in mixed solvents 2946; mol of KI in enjoblary hydrin	9.190

Constants, der Atomphysik (Roth, Scheel, book rev.)	3142
Copper, vapor pressure of, 617; sepn. of Fe and Al from, 676; catalytic combination	
of C2H4 and H in the presence of metallic, 1196, 2235; action of solns. of alkali	
hydroxides on, 1237; action of SeOCl2 on, 2091; adsorption of gases by,	
	2861
	3141
Copper ammonium formate, absorption of CO by, solns	
Copper chloride, equil. in systems of CuCl ₂ with HCl and H ₂ O	663
Copper oxide, vapor pressure of, 617; action of solns. of alkali hydroxides on,	0.00
the second secon	2305
Copper salts, complexes in solns. of, 1353; as promoters in the Fe salt catalysis of	2000
the state of the s	2512
	2012
Copper sulfate, dissociation pressures of hydrates of, 349; vapor pressures of	
	1863
	1944
Corrections.	
Cottonseed oil, phytosterols of.	
Creatinine, kinetics of the conversion of creatine into, in HCl solns

3,4-Diacetyl-2,5-diimino-2,3,4,5-tetrahydro-1,3,4-thiodiazole	
Diadrenaline ether, dihydrochloride	
Dialkylbarbituric acids, with tertiary amino grouping	1757
p-Diaminodiphenylamine, action of Br and HNO₃ on	
Diaminodiphenylthiourea, reaction with CS ₂ , 2353; reaction of glacial AcOH on	
Dianisidine, tetraphthalaldehyde and	
2,2'-Di-p-anisoylarsenobenzene	513
5.5-Diarylbarbituric acids.	
Diazobenzeneimide, isosterism of phenyl isocyanate and	
Dibenzalacetone, reaction of, with (AcO) ₂ Hg.	
2,2'-Dibenzoylarsenobenzene	
4,4'-Dibenzoylarsenobenzene	512
Dibenzoylethylene, new method of prepg., and related compds.	
Dibenzyl ether, 2358; action of Br on	
Di-p-benzyloxyhexaphenylethane, degree of dissociation of	215
2,6-Dibromo-4-acetylamino-5-methylphenol, and acetate and benzoate 472	
2,6-Dibromo-4-acetylaminophenol, acetate and benzoate	471
Dibromo- <i>p</i> -arsinobenzoyl- <i>o</i> -anisidide	761
p-Dibromobenzene, luminescence of compds. formed by the action of Mg on, and	
related compds., 278; soly, relations of	. 636
2,6-Dibromo-4-benzoylamino-5-methylphenol, acetate	
2,6-Dibromo-4-benzoylaminophenol, and acetate	471
Di-(bromoethylidene)mannitol	749
2,5-Dibromoterephthalic acid, and di-Et ester	
2,5-Dibromo- <i>p</i> -xylene	
Dichloroacetic acid, direct conversion of derivs, of, into derivs, of trichloroacetic	
acid	1994
Dichloro-p-arsinobenzoyl-o-anisidide	761
Dichloro-o-arsinobenzoyl chloride	511
Dichloro-p-arsinobenzoyl ethyl anilide	761
p-Dichlorobenzene, 272; utilization for synthesis in the diphenic acid series	
2,5-Dichlorobenzenesulfonic acid, NH ₄ salt of	
2,3-Dichloro-5-benzoxy-1,4-naphthoquinone	
Di-(4-chlorobenzoylethane)	
Di-(4-chlorobenzoyl)ethylene.	
5,5-Dichlorodiphenic acid, and anhydride	1020
$\alpha, \gamma$ -Dichlorohydrin, purity of, prepd. by the action of HCl on glycerol	2771
Dichlorohydroxyethylidenebisnitroanilines	
Dichlorojugione, Na salt of	
Dichloromethyldimethylcarbinol, ester of carbamic acid.	478
2,5-Dichlorophenylimino-2,3,4,5-tetrahydro-1,3,4-thiodiazole	
2,0-12temorophenymmno-2,0,-t,0-temanydro-1.5,-t-inioniaxole

Fluorenone, reaction with phenol	3075
Fluorenone series	3071
Fluorescence, of oxidation products of Grignard compds., 2069; im Lichte der	
Neueren Atomtheorie (Pringsheim, book rev.)	3143
Fluoroheptaacetylcellulose	834
Fluorotetraacetylfructose	2388
Fluorotetraacetylglucose	834
Fluorotriacetylxylose	835
Foods, Use of, for the Preservation of Vitality and Health (McCollum, book rev.).	
259; Vital Factors of (Ellis, Macleod, book rev.), 559; Analysis (Thurston,	
book rev.)	1089
Formaldehyde, detn. in paraformaldehyde, 1493; detn. in presence of substances	
found in formalin, 2150; detection of	
Formic acid, decompn. by H2SO4, 447; catalytic decompn. in acetic anhydride,	
455; reactions of, at the surface of alumina, 809; detn. of	
Formulas, simplified method of writing "electronic".	
Freezing points, correction to the, diagram of Pb-Na alloys.	
Fructose, action of dry HBr on	182
Fuller's earth, effect on pinene and other terpenes.	728
Fumaric acid, phys. properties of, 1003; prepns. from, 2156; salts of	
Furalacetone	
Furalacetophenone	
Furfural, reduction of, and its derivs	
Furoin	
β-Furylaerylic acid	
Furyl alcohol	
GALLIC-acid-benzein	2992
Gallium, at. wt. of	1155
Gases, app. for working with, at low temp., 332; soly. relations of certain, 682;	
sp. heats of polyatomic, at low temps., 874; adsorption by oxide catalysts,	
887; influence of temp., pressure and supporting material for the catalyst on	
the adsorption of, by Ni, 920; heat capacities and entropies of diatomic	
and polyatomic, 1445; electrode, 1723; entropy of diatomic, and rotational	
sp. heat, 2277; adsorption by Cu, 2296; adsorption of mixed, by charcoal	2638
Geber, Alchemy of (Darmstaedter, book rev.)	1341
Gelatin, d. and hydration in, sols, 2613; points of min. swelling of ash-free	3139
Germanium, extn. from Ge-bearing ZnO, 1380; metallic-prepn. of fused-phys.	
and chem, properties	2033
Germanium dioxide, prepn. of, free from As-detection of minute amts. of As in,	
1380; reduction of	2033
Glass, adsorption of toluene vapor on plane, surfaces, 63; evidence from the sp.	
heats of glycerol that the entropy of a, exceeds that of a crystal at the abs.	
zero, 93; -to-metal joint, 716, 2135; wetting of, by Hg	2255
Gluconyl-p-arsanilic acid	761
d-Glucose, action of dry HBr on	181

Glycerol, evidence from the sp. heats of, that the entropy of a glass exceeds that of a crystal at the abs. zero, 93; partition of C ₂ H ₂ between, and ethylene glycol,	
trimethylene glycol and 1,2-propylene glycol	3123
Glycine, characteristics of the 2 cryst. forms of	
Gold, effect of light and H-ion conen. on the formation of colloidal, in silicic acid	
gel	
Graphite, some properties of, 572; structure and dimensions of	
Graphs, method for reproducing, in quantity	
Gravitation, Theory of General Relativity and (Silberstein, book rev.)	864
Grignard reagents, quant. estn. of the, 150; reaction between ethylenic hydro-	
carbons and the, 554; prepn. of dialkyl Hg compds. from the, 820; action on	
keto acids, 1086; yields of some	2462
f HALIDES, electrometric titration of the, in the presence of one another, 623;	
reaction of org. Hg compds. with	
Halogen-alkyl sulfonates, reaction between organomagnesium halides and	
Halogenation, 480; of the acetals	1552
Halogens, simultaneous detn. of S and, in org. compds., 255; at. vols. of, and	
alkali metals in combination, 423; diams. of atoms of, 424; absorption by	
mercurous salts	
Hay, amino acids of clover	815
Heat, capacities and entropies of diatomic and polyatomic gases	
Heat of coagulation, of Fe ₂ O ₃ hydrosol with Na ₂ SO ₄	311
Heat of formation, of PbO	
Heat of ionization, and at. structure	
Heat of solution, of TI in dil. Tl amalgams	
Heat of vaporization, of Hg and Cd	
Henry's law, apparent deviation from, for the system NH ₃ -H ₂ O	
Hexahydrophenyl semicarbazide, 3006; decompn. at elevated temps	
Hexahydrophenyl urazole	
Hexamethylenetetramine, crystal structure of	22
Hexosamines, Their Derivs., and Mucins and Mucoids (Levene, book rev.)	
History, of Chemistry (Venable, book rev.), 1854; Beiträge zur, der Naturwis-	1001
senschaften und der Technik (von Lippmann, book rev.)	
Holmium, absorption spectrum of	912
Homococaine, prepn. of an isomer of	
Homoisophorones	
Homomesityl oxide	1922
Homophorone	1924
p-Homosaligenin	2420
Humin, origin of the, formed by the acid hydrolysis of proteins	550
Hydantoins, synthesis of polypeptide	843
Hydrates, dissociation pressures of certain salt, 342; vapor pressures of certain	
hydrated metal sulfates	578
Hydration, of AcOH and HCl	702
Hydrazine, action on the arylmonothioamides of carbethoxyethyl malonate	
Hydrazobenzene, 1786; reduction of	
$Hydrazodi-\alpha$ -naphthyldithiodicarbonamide	
Hydrazodithiodicarbonamides, ring closure of, with acetic anhydride	
Hydrazomonothiodicarbonamides, ring closure of, with acetic anhydride	
Hydriodic acid, activity of the ions of, 2852; catalytic decompn. of H ₂ O ₂ in a Br-	

bromide soln.—rate measurements in dil. solns. and in the absence of sulfate,	0040
and their interpretation as a function of the activity product of	
Hydrobromic acid, action of dry HBr on carbohydrates and polysaccharides	176
Hydrocarbons, reaction between ethylenic, and the Grignard reaction, 554; addn.	
of NCl₃ to unsatd	3084
Hydrochloric acid, condensation of a mixt. of NO and dry HCl at liquid-air	
temp., 332; equil. in the systems, NiCl ₂ , CoCl ₂ , CuCl ₂ -H ₂ O-, 663; hydration	
of, 702; precision measurement of the compn. of the constboiling mixt. of	
water and, 1220; oxonium compds. in the vapor state, 1675; action of concd.,	
on different celluloses, 1729; conductance of dil	2017
Hydrogen, prepn. of active, 261; at. wt. of, 563; dissociation of mol., from the	
entropies of diatomic and monatomic, 673; detn. in org. compds. with As and	
with Hg, 998; catalytic combination of C ₂ H ₄ and, in the presence of metallic	
Cu, 1196, 2235; analysis of, for traces of N, 1688; vapor pressure of, 2326;	
water-jacketed, electrode, 2503; equilibria in systems involving Ca, N and,	
2559; diffusion through metals	2857
Hydrogen bromide. See Hydrobromic acid.	
Hydrogen chloride. See Hydrochloric acid.	
Hydrogen hexasulfide	601
Hydrogen ion, factors detg. the activity of, 702; catalysis by acids2813,	
Hydrogen-ion concentration, modification of Gillespie's method for the detn. of,	
940, 3142; relation to the flocculation of a colloidal clay, 1243; source of	
trouble in electrometric measurements of, 1904; effect on the formation of	
colloidal Au in silicic acid gel, 2261; Detn. of (Clark, book rev.)	3144
Hydrogen peroxide, action upon certain phenyl-substituted uric acids, 135; in-	
hibition of the photochem. decompn. of solns. of, 650, 1210; catalytic de-	
compn. of, in a Br-bromide soln., 1251, 2048; catalytic decompn. by ferric	
salts, 2493; Cu salts as promoters in the Fe salt catalysis of, 2512; action	
on certain phenyl-substituted uric acids.	3142
Hydrogen persulfides, soly. of S in	601
Hydrogen sulfides, errors in the detn. of	
Hydrolysis, intercepted	
Hydroquinone, action of Br and HNO ₃ on.	481
Hydrosols. See Colloids.	
Hydrouracil, reduction of uracil to	2702
Hydroxamic acids, formation from ketene, 515; reactions of $\alpha$ -phenyl- $\beta$ -hy-	
droxyurea and of $\alpha, \alpha$ -diphenyl- $\beta$ -hydroxyurea interpreted from the stand-	
point of their, structures	1472
Hydroxyaldehydes, simplification of the Gattermann synthesis of	2373
p-Hydroxybenzoylbenzene-o-sulfonic acid	488
p-Hydroxybenzoyl- $o$ -benzoic acid, triacetate of the $p$ -hydroxyanilide of	
o-Hydroxybenzylacetamide	
o-Hydroxybenzylamine, diacyl derivs. of.	
o-Hydroxybenzylbenzamide	
α-Hydroxybenzyldiphenylphosphine oxide	168
4-Hydroxybenzylhydantoin-3-propionic acid, 853; Et ester.	855
Hydroxybenzylphosphonic acid, diphenyl ester of	766
3-Hydroxy-1-carvomenthyl-5-phenyltriazole	
3-Hydroxy-1,2-dimethyl-1,3-cyclopentane-dicarboxylic acid, dimethyl ester of,	5000
and 3-amide of the lactone of	2260
3-Hydroxy-1-fenchyl-5-phenyltriazole.	
3-Hydroxy-1-hexahydrophenyl-5-phenyltriazole	

α-Hydroxyisopropylphosphonic acid, diphenyl ester and acetyl deriv. of Hydroxylamine, prepn. of, hydrochloride, 188; transference expts. with electromeric derivs. of, 355; ketene and, 520; action of, on the arylmonothio-	766
amides of carbethoxyethyl malonate	
Hydroxyl radical, effect of relative positions of, and amino radical in the mi-	
gration of acetyl from N to O	469
1-Hydroxymercurimethyl-1,2-dihydrobenzofurans	
3-Hydroxymercuri-5-nitrosalicylalaniline, anhydride of	1333
3-Hydroxy-6-methoxy-2-(2-hydroxy-4-methylbenzoyl)benzoic acid	
3-Hydroxy-6-methoxy-2-(4-methoxy-1-methylbenzoyl)benzoic acid	
$\alpha$ -Hydroxy- $\alpha$ -methylbenzylphosphonic acid, diphenyl ester of	
$\alpha$ -Hydroxy- $\alpha$ -methyl- $\beta$ -chloroethylphosphonic acid, diphenyl ester of	767
1-Hydroxy-2-methyl-5,8-dimethoxyanthraquinone	
1-Hydroxy-3-methyl-5,8-dimethoxyanthraquinone	
1-Hydroxy-4-methyl-5,8-dimethoxyanthraquinone	
2-Hydroxy-3-methylphenylarsonic acid	
α-Hydroxy-α-methylpropylphosphonic acid, diphenyl ester of	766
Hydroxynaphthoquinone, studies	
1-Hydroxy-2-phenyl-4-(3,4-methylenedioxyphenyl)pyrroline	
2-Hydroxy-1,5,5-trimethylcyclopentanoic acid, Me ester	
d-cis-2-Hydroxy-1,2,3-trimethylcyclopentanoic acid, Me ester	
l-trans-3-Hydroxy-1,5,5-trimethylcyclopentanoic acid, Me ester	
o-Hydroxytriphenylcarbinol, tautomerism of	
o-Hydroxytriphenylchloromethane	198
o-Hydroxytriphenylmethyl	
Hypnotics, new, of the barbituric acid series	243
CE, m. p. of, on the abs. temp. scale	2124
Imido-β-resorcylic acid, Me ester	
Imido thiol esters, production by the condensation of thiocyanates with re-	
sorcinol or phloroglucinol	
Imidothiol-β-resorcylic acid, esters and their salts	
Imidothiol-2,4,5-trihydroxybenzoic acid, Me ester hydrochloride	
Indicators, lecture table demonstration of action of	
Injury, in Relation to Cond. and Permeability (Osterhout, book rev.)	1861
Inorganic chemistry, (Denham, book rev.), 258; Inorg. Chem. Synonyms and	
Other Useful Chem. Data (Darling, book rev.), 558; Textbook for Schools	
(Holmyard, book rev.), 1575; ein Lehrbuch zum Weiterstudium and zum	
Handgebrauch (Ephraim, book rev.), 2473; Lab. Exercises in (Norris, Mark,	
book rev.)	2473
Interferometer, cell for use as a pressure gage	1714
Invertase, spontaneous increase in, activity of banana exts	1539
Iodate, electrometric titration of	2013
Iodides, detn. of, 629, 631; reaction of strong oxidizing agents upon	1422
Iodimetry, standardization of solns. used in	1358
Iodine, luminous discharge in-detn. of the ionization potential of, 337; reaction	
between AgClO ₄ and, 398; estn. by Na ₂ S ₂ O ₃	1361
Iodine pentoxide, soly. in H ₂ SO ₄	108
Iodoacetic acid, NH4 salt of	
o-Iodobenzoic acid, NH4 salt of	
p-Iodobenzoic acid, NH4 salt of	3000

Iodochloride-2-chloroethylene, org. products from the decompn. of	186
Iodochloride-1,2-dichloro-2-iodoethylene, org. products from the decompn. of	186
3-Iodochloride-4-methoxyacetophenone	2165
Iodochlorides, spontaneous decompn. of unsatd. aliphatic	182
$\alpha$ -Iodo- $\beta$ -ethoxy- $\beta$ -phenylpropiophenone	
o-Iodomercurianisole	1754
o-Iodomercuriphenetole	1754
<i>p</i> -Iodomercuriphenetole	
o-Iodomercuriphenol ethers, reaction with KCNS and with Na ₂ S ₂ O ₃	
p-Iodomercuriphenol ethers, reaction with KI and with KCNS	1755
3-Iodo-4-methoxyacetophenone	2164
$\alpha$ -Iodo- $\beta$ -methoxy- $\beta$ -phenylpropiophenone	
<i>p</i> -Iodophenylmercuric acetate	1328
3-Iodoso-4-hydroxyacetophenone	2165
3-Iodoso-4-methoxyacetophenone	2165
Ionization, electrolytic, of alcs., 1348; of salt vapors	2803
Ionization, gaseous, detn. of the, potential of I, 337; possible detn. of the, po-	
tential of Br, 1192; α-ray bulb as a source of	2593
Ions, electrolytic, activities of the, of KOH in aq. soln., 70; transference numbers	
of KOH in aq. soln., 77; transference expts. with electromeric derivs. of	
hydroxylamine, 355; effect of sucrose on the activities of certain, 1627;	
moving boundary method for detg. transference numbers, 2246; activity	
of the, of HI in aq. soln., 2852; individual thermodynamic properties of,	
2898; activities in homogeneous catalysis	3141
Iridium, detn. in Pt alloys	2820
Iridium compounds, equilibria between the acido- and aquo-iridium pentammines.	378
Iron, sepn. from Mn and certain other elements, 676; detn. of Mn in, 1615;	
action of SeOCl ₂ on	2093
Iron alloys, detn. of Mn in	1615
Iron group, qual. analysis of the	438
Iron oxide (Fe ₂ O ₃ ), constitution of, hydrosol, 297; heat of coagulation of, hydro-	
sol with Na ₂ SO ₄ , 311; ferric salt as the "soln. link" in the stability of, hy-	
drosol, 2522; prepn. and analysis of, sols, 2533; decompn. of KClO4 and	
its catalysis by	
Iron salts, catalytic decompn. of H ₂ O ₂ by ferric, 2493; Cu salts as promoters in	
the, catalysis of H ₂ O ₂ , 2512; ferric salt as the "soln. link" in the stability of	
Fe ₂ O ₃ hydrosol, 2522; decompn. of pyrimidines by ferrous, 2972; oxidation of	
uric acid with ferrous	2980
Iron sulfate, absorption spectra of the complex compds. of, with NO, 1863; dis-	
sociation pressures of hydrates of	349
5-Isoamyl-5-α-acetophenetidinopropylbarbituric acid	
Isoamyl-γ-acetophenetidinopropylmalonic acid, Et ester	1761
Isoamyl alcohol, and reaction with $\beta$ - $\gamma$ -dibromopropyl isothiocyanate	485
Isoamyl-γ-bromopropylmalonic acid, Et ester	
5-Isoamyl-5-γ-diethylaminopropylbarbituric acid	1760
Isoamyl-γ-diethylaminopropylmalonic acid, Et ester	
5-Isoamyl-5- $\gamma$ -ethylanilinopropylbarbituric acid	1761
Isoamyl-γ-ethylanilinopropylmalonic acid, Et ester	
Isoamylurea	
Isobutyl alcohol, a reaction with $\beta$ - $\gamma$ -dibromopropyl isothiocyanate	
Isocampholactone structure of	2366

Isocyanic acid, isosterism of phenyl ester of, and diazobenzeneimide, 1734; Ph	
ester, reaction with $\beta$ -phenylhydroxylamine	
Isogranatanine, derivs	2738
Isogranatoninecarboxylic acid, Et ester, 2747; Et ester and hydrochloride	
thereof	2749
Isomers, mechanism underlying the reaction between aldehydes or ketones and	
tautomeric substances of the keto-enol type	1975
Isophthaldehyde, and benzidine	525
Isopropyl alcohol	1336
Isopropylanthraquinone thioether, oxidation of, and of the dithioethers	1835
Isopropyl semicarbazides	3007
Isosterism, of phenyl isocyanate and diazobenzeneimide	1734
Isothiocyanic acid, interaction of aliphatic alcs. and $\beta$ - $\gamma$ -dibromopropyl esters of,	
482; p-acetylaminophenyl ester, 2354; interaction of aliphatic alcs. and $\beta$ - $\gamma$ -	
dibromopropyl ester of	3142
Isotopes, 1426; (Damiens, book rev.), 2774; sepn. of Hg into, in a large app.,	
591; intern. table of, 868; sepn. of	1592
THOT ONTO 11 decides of	1070
JUGLONE, chlorination of	1910
KETENE, 3095; formation of hydroxamic acids from, 515; and benzhydroxamic	
acid	521
Keto acids, action of the Grignard reagent on	
γ-Ketobutylethylene oxide	2437
3-Keto-1,2-dimethylcyclopentanecarboxylic acid, and action of Grignard's re-	
agent thereon	2370
Ketones, hydrolysis of proteins in the presence of, 550; mechanism underlying	
the reaction between, and tautomeric substances of the keto-enol type, 1975;	
catalytic reduction of $\gamma$ -nitro-, 2144; addn. of Hg salts to $\alpha,\beta$ -unsatd., 2763;	
ketenic decompn. of	3095
2-Keto-3-phenyltetrahydro-1,3-oxazine.	726
2-Keto-3-o-tolyltetrahydro-1,3-oxazine	727
Kinetics, of the conversion of creatine into creatinine in HCl solns	2242
LANTHANUM, at. wt. of, 570; prepn. and properties of	614
Laws, 3rd law of thermodynamics, 93; apparent deviation from Henry's, for the	
system, NH ₃ -H ₂ O.	915
Lead, at. wt. of, 571; system, Sb-, 1683; action of SeOCl ₂ on, 2093; diffusion of	
H through, 2861; activities of Zn, Cd, Sn, Bi and, in their binary liquid	
mixts., 2865; at. wt. of, from the Belgian Congo	2954
Lead alloys, correction to the fp. diagram of, with Na	
Lead compounds, diplumbic hexaethyl	
Lead fluoride, surface energy of	
Lead iodide, surface energy of	
Lead oxides, action of SeOCl ₂ on, 2093; free energy and heat of formation of	
PbO, 2632, 3142; action of S upon p-toluidine in the presence of litharge	3045
Lecture experiments, demonstrating adsorption, 437; demonstration of solubilities	
or of indicator action	1471
Liesegang rings	
Light, action on As ₂ S ₃ hydrosol, 16; partial and consecutive sections in the photo-	
sensitive system; quinine sulfate, H ₂ CrO ₄ and H ₂ SO ₄ , 1891; effect on the	
formation of colloidal Au in silicic acid gel, 2261; filter	
Light, ultraviolet, reduction of CO ₂ by, 1184; action upon diketones	

Lignoceric acid, detn. of the mixt. of arachidic acid and, in peanut oil	113 3142 815 1944
Liquids, mutual soly. of, 1148; collodion membrane for liquid junctions, 1271; dielec. consts. of org., at the b. p., 2794; extremely dry	2836
Lithium chloride, vapor pressure of, solns, at 20°	
and related compds., 278; of organo-Mg halides	2058
MAGENTA, adsorbed moisture and water of crystn. in	1662
positive elements—replacement of Na and K by Al and	
Mg halides  Magnesium stannide, crystal structure of  Magnesium sulfate, dissociation pressures of hydrates of, 349; vapor pressures of	2058 2777
hydrates of	578
Maleic acid, phys. properties of, 1003; prepns. from, 2156; salts of	2341
Manganese, sepn. of Fe and Al from, 676; detn. in Fe, steel and other alloys, 1615; interference of Co in the bismuthate method for	2600
as catalyst in oxidation of CO	
Manganese sulfate, vapor pressures of hydrates of	
Mannose, from white spruce cellulose	1008
Manometer, improved optical lever, 59; upper range of the quartz-fiber	1637
Mass effect, in the entropy of substances	80
Medicine, Die Physikalische Chemie in der Inneren (Schade, book rev.)2474,	2475
Membrane, collodion, for liquid junctions	1271
Menthyl semicarbazide	
Mercaptans, reactions of anthraquinonesulfonic acids with	
1-Mercaptobenzothiazole, prepn. and properties of, its homologs and derivs	
1-Mercapto-3,5-dimethylbenzothiazole	
1-Mercapto-5-ethoxybenzothiazole	
1-Mercapto-5-methoxybenzothiazole	
1-Mercapto-3-methylbenzothiazole	
1-Mercapto-4-methylbenzothiazole	
1-Mercapto-5-methylbenzothiazole	
Mercuribisphenol ethers, reaction of HgCl ₂ with	
Mercuric cyanide, estn. of	1400
Mercuric perchlorate, prepn. of	
· · · · · · · · · · · · · · · · · · ·	
1,1-Mercuridimethylenebis-(4-methyl-1,2-dihydrobenzofuran)	
Mercurous salts, absorption of halogens by	
Mercury, at. wt. of, 571; sepn. into isotopes in a large app., 591; relative stability	
of the C-Hg linkage in dialkyl Hg compds., 820; influence of mercuric, upon	

HBrO3 reactions, 1417; sepn. of isotopes—application of systematic frac-	
tionation to, in a high-speed evapndiffusion app., 1592; heat of vaporization	
of, 2080; wetting of glasses by, 2255; vapor pressure of	2325
Mercury bisaceto diethylmethane	
Mercurybisacetodimethylmethane	
Mercurybisbenzoylmethane	
Mercury compounds, prepn. of dialkyl, from the Grignard reagent—relative sta-	
bility of the C-Hg linkage in dialkyl, 820; detn. of C and H in org., 998;	
prepn. of p-tolyl, 1066; reaction of org., with halides, 1068; prepn. of the, of	
the phenyl halides, 1321; of salicylaldehyde and the nitrosalicylaldehydes,	
1330; Hg derivs. of phenol ethers, 1753; Me and Et ammonium-mercuric	
bromides, 1763; mercurated 1-methyl-1,2-dihydrobenzofurans, 1842; compd.	
of Et mercuric chloride and NH ₂	3082
Mercury di-tert-amyl	822
Mercury di-sec-butyl	821
Mercury di-tert-butyl	822
Mercury di-sec-octyl	821
p-Mercury ditolyl, reaction with sulfonyl halides	
Mercury salts, addn. of mercuric salts to $\alpha,\beta$ -unsatd. ketones, 2763; behavior	
of mercuric salts of org. acids toward heat	2961
Metabolism, Introduction to the Chemistry of Plant Products (Vol. II) Metabolic	
Processes (Haas, Hill, book rev.)	2222
Metals, glass-to-metal joint, 716, 2135; reactions of strongly, electropositive,	
with org. substances in liquid NH ₂ soln., 768, 779, 1780, 2756; action of	
SeOCl ₂ on various, 2090; displacement from solns. of their salts by less elec-	
tropositive elements, 2788; solns., 2828; diffusion of H through	2857
p-Methoxyacetophenone, relation between mol. structure and odor in derivs. of	
2-Methoxy-5-acetylazidobenzene	
2-Methoxy-5-acetyldiazobenzene, perbromide.	
2-Methoxy-4-aminophenylarsonic acid	
o-Methoxybenzoic acid, NH ₄ salt of	
4-Methoxybenzophenone-2'-arsenious acid	513
4-Methoxybenzophenone-4'-arsinoacetic acid	514
4-Methoxybenzophenone-2'-arsonic acid	512
4-Methoxybenzophenone-2'-dibromoarsine	513
4-Methoxybenzophenone-4'-dibromoarsine	514
4-Methoxybenzophenone-2'-dichloroarsine	513
4-Methoxybenzophenone-4'-dichloroarsine	514
4-Methoxybenzophenone-2'-diiodoarsine	513
4-Methoxybenzophenone-4'-diiodoarsine	514
Methoxydichlorophosphine, addn. to benzaldehyde	765
2-Methoxy-1-methyl-5,8-dihydroxyanthraquinone	2461
2-Methoxy-4-nitrophenylarsonic acid	
2-Methoxyphenylarsonic acid	
4-Methoxyphenylarsonic acid	
o-Methoxytriphenylcarbinol, and derivs	202
p-Methoxytriphenylcarbinol	217
o-Methoxytriphenylmethyl, 202; action of I upon	203
p-Methoxytriphenylmethyl	207
p-Methoxytriphenylmethyl bromide	218
p-Methoxytriphenylmethyl chloride	217
p-Methylacetophenone anil.	240

Methyl alcohol, sepn. and identification of, in mixt. with anhyd. acetone, 543;	
detection of	
N-Methyl-p-amino-o-chlorophenol, sulfate	2192
Methylammonium-mercuric bromides	1763
1-Methylanthraquinone	
4-Methylbenzophenone-2'-arsonic acid	512
1-Methyl-1,2-dihydrobenzofurans, mercurated	1842
Methylene blue, adsorbed moisture and water of crystn. in	1659
$\beta$ -(3,4-Methylenedioxyphenyl)- $\gamma$ -aminobutyrophenone	2148
$\beta$ -(3,4-Methylenedioxyphenyl)- $\gamma$ -nitrobutyrophenone	
Methylenesaligenins, aryl	
Methyl ether, oxonium compds. in the vapor state	
Methylethyl ketone, condensation products of, 1917; ketenic decompn. of, 2167;	
decompn. of	3099
Methylguanidine, sulfate	
4-Methylhydantoin-3-hydroxybenzyl-3-propionic acid.	
1-Methyl-3-hydroxybenzene-2-arsonic acid.	
1-Methyl-3-hydroxybenzene-4-arsonic acid	803
2-Methyl-4-hydroxyphenylarsonic acid.	
3-Methyl-4-hydroxyphenylarsonic acid	801
Methylisobutylcarbinol	
Methylketene	
α-Methyl-α(p-methoxybenzyl)diglycolamidic acid, urea of	
8-Methylnonic acid	
8-Methylnonyl vanillyl amide.	
2-Methyl-2,4-pentanediol, partition of C2H2 between, and ethylene glycol, tri-	0100
methylene glycol and glycerol	
7-Methyl-9-phenylpseudouric acid	141
2-Methyl-4-phenylpyrrolidine	
7-Methyl-9-phenyluric acid	
Methylpropylcarbinol	
Molybdenite, cryst. structure of	
Molybdenum, electrometric titration of, with titanous salt	
Mucic acid, detn. of	
Mucins, (Levene, book rev.)	
Mucoids, (Levene, book rev.)	1861
M	
α-Naphthalenesulfonic acid, NH ₄ salt of	
β-Naphthalenesulfonic acid, NH ₄ salt of	
Naphthenic acid, from Japanese petroleum	
lpha-Naphthol aldehyde	
β-Naphthol aldehyde	
$\beta$ -Naphtholazo- $\alpha$ -hydroxybutyrophenone	
$\beta$ -Naphtholazo- $\alpha$ -hydroxyisovalerophenone	1993
$\beta$ -Naphtholazo- $\alpha$ -hydroxypropionophenone	
β,β-Naphtholylacrylic acid, 2157; and Me ester	2158
α-Naphthylamine, trichloroacetate	1997
Neoarsphenamine, examn. of—constitution of the French drugs	
Neodymium, absorption spectrum of	909
Neutralization, bimetallic electrode system applied to, reactions	
Neutral salt action, on the temp. coeff. of reaction velocity	
Nickel, sepn. of Fe and Al from, 676; comparison of the at. wts. of terrestrial and	

meteoric, 694; influence of temp., pressure and supporting material for the	
catalyst on the adsorption of gases by, 920; action of SeOCl ₂ on, 2093; diffu-	
sion of H through	0061
Nickel chloride (NiCl ₂ ), equil. in systems with HCl and H ₂ O, 663; analysis of,	4001
	500
694; sp. gr. of anhyd	700
Nickel sulfate, dissociation pressures of hydrates of	349
Nicotinic acid, nitrate, 2743; and hydrochloride and Et ester	
Nipecotic acid, derivs	2746
Niton. See Radon.	
Nitric acid, action of Br and, on org. compds	480
Nitric oxide, absorption spectra of the complex compds. of CuSO4 and FeSO4 with,	
1863; condensation of a mixt. of HCl and, at liquid-air temp	332
m-Nitroaniline, trichloroacetate	1997
Nitroarylarsonic acids, reduction of	1312
Nitrobenzene, reduction by Na in liquid NH2	1780
o-Nitrobenzoic acid, hydrolysis of Me ester of, in acid soln	321
p-Nitrobenzoyl-n-butylamine	3088
4-Nitro-1,1'-binaphthyl	1570
p-Nitrochloroacetanilide	1997
2-Nitro-4-chloroaniline	1026
4-Nitrochlorobenzene-2-sulfonic acid, NH ₄ salt of	
2-Nitro-4-chlorobenzoic acid.	1026
3-Nitro-2-chlorobenzoic acid.	
5-Nitro-2-chlorobenzoic acid	
2-Nitro-4-chlorobenzonitrile	
p-Nitro-o-chlorophenol	
Nitro compounds, catalytic reduction of $-\alpha,\beta$ -unsatd., 1281; catalytic reduction	
of	
V1	2144

9-Phenylxanthane, conversion of the carbinol into	196
9-Phenylxanthylium chloride, reduction of	
Phloroglucinol, production of imido thiol esters by the condensation of thiocyanates	
with	1744
Phosgene, solubilities of.	687
Phosphorescence, im Lichte der Neueren Atomtheorie (Pringsheim, book rev.)	
Phosphoric acid, electrometric study of the neutralization of, by Ca(OH) ₂	881
Phosphorus, black colloidal suspensions in, 67; vol. estn. of small amts. of	668 $762$
Phosphorus halides, addn. reactions of	102
Photochemistry, inhibition of the photochem, decompn. of H ₂ O ₂ solus., 650, 1210;	
decompn. of solid oxalic acid, 1398; temp. coeff. of photochem. reaction rate,	
2285; study of acetylchloroaminobenzene, 2574; Grundriss der, in elementarer Darstellung als Einführung in das Studium (Plotnikow, book rev.)	2149
Photographic developer, new	
Photography, of the disintegration of an atom, 2095; sensitiveness of AgI	
Phthaleins, absorption spectra of	
Phthalidecarboxylic acid, mercuric salt.	
Physical chemistry, Course of Lab. Expts. on Physico-chem. Principles (Sherrill,	4901
book rev.), 2218; in der Inneren Medizin (Schade, book rev.), 2474, 2475;	
Landolt-Börnstein Physikalisch-Chemische Tabellen (Roth, Scheel, book	
rev.)	2773
Physics, Konstanten der Atomphysik (Roth, Scheel, book rev.)	
Phytosterols, of corn oil, cottonseed oil and linseed oil.	
Pigments, Carotinoids and Related (Palmer, book rev.)	
Pinch clamp, screw modification of the Mohr.	1723
Pinene, effect of fuller's earth on	
Piperidine, reaction with $\beta$ - $\gamma$ -dibromopropyl isothiocyanate, 485; action on $o$ -	
chlorobenzoic acid and on 3,5-dinitro-2-chlorobenzoic acid	
2-Piperidino-5-nitrobenzoic acid.	
$n$ -(Piperidylpentamethylene)-S-diphenyl- $\alpha$ -naphthylmethyldithiourethane	548

$N ext{-Piperidyl-}S ext{-triarylmethyldithiourethans},$ dissociation of, with formation of	
triarylmethyls	544
Plant products, Introduction to the Chemistry of (Haas, Hill, book rev.)	
Plasticity, Fluidity and (Bingham, book rev.)	865
Platinum alloys, detn. of Ir in	
Platinum metals	2820
Platinum oxide, as a catalyst in the reduction of org. compds.—activation of the	
catalyst by the salts of certain metals, 1071; a catalyst in the reduction of	
org. compds	3029
Poison ivy, Dermatitis from (McNair, book rev.)	3149
Polypeptides, synthesis of polypeptide hydantoins, 843; occurrence in the un-	
germinated wheat kernel	2137
Polysaccharides, action of dry HBr on, 176; polymerization of, 2433; reactions	
relating to	3124
Potassium, resistance-temp. coeff. of concd. solns. of, in liquid NH2 and the sp.	
conductance of solns. of, in liquid NH3 at intermediate concns., 2551; dis-	
placement of metals from solns, of their salts by less electropositive elements—	
replacement of Na and, by Mg and Al, 2788; sepn. and detn. of Na and	2072
Potassium amide, phase relations in the system Na amide	712
Potassium carbonate, equil. in system, H ₂ O and the chlorides and carbonates of	
Na and K and in the system, H ₂ O and the sulfates and carbonates of Na and	
K	2935
Potassium chlorate, decompn. of—spontaneous decompn. temps. of mixts. of	2000
MnO ₂ and, 1343; promoter action in the decompn. of	2330
Potassium chloride, transference numbers of Na and K in mixed chloride soln.,	
1121; effect of sucrose on the activities of the ions of, 1627; equil. in system,	
H ₂ O and the chlorides and carbonates of Na and K	
Potassium hydrogen fluoride, cryst. structure of	
Potassium hydroxide, activities of the ions of, in aq. soln., 70; transference num-	2120
bers of, in aq. soln	77
Potassium iodide, mol. cond. of, in epichlorohydrin.	
Potassium ion, transference numbers of Na and, in mixed chloride soln	
Potassium perchlorate, decompn. of, and its catalysis by Fe ₂ O ₂ , 1134; soly. in salt	1141
solns. and the corresponding activity relations	2652
	171
Potassium permanganate, oxidation of propylene glycol with	111
Potassium sulfate, equil. in the system, H ₂ O and the sulfates and carbonates of Na	0095
and K.	
Potential, electric, detn. of abs. single electrode, 37; detn. of the ionization, of I,	
337; electrode-, of Bi, 360, 371; possible detn. of the ionization, of Br, 1192;	
measurements with a satd. KCl bridge or with concn. cells with a liquid	
junction, 1716; reduction, of quinones	
Praseodymium, absorption spectrum of, 908; detn. of	
Precipitation, mechanism of the mutual, of certain hydrosols	
Pressure, dissociation, of certain salt hydrates, 342; compressibility, internal, and	
at. magnitudes, 422; calcn. of relative internal, from soly., 638; interferometer	
cell for use as a, gage, 1714; effect on overvoltage	
Propyl alcohol.	1335
Propylene, action of SeOCl ₂ on	1795
Propylene glycol, oxidation with $\mathrm{KMnO_4}$ , 171; partition of $\mathrm{C_2H_2}$ between ethylene	
glycol, trimethylene glycol, and glycerol and	3123
Proteins, cataphoresis of, 954; origin of the humin formed by the acid hydrolysis	
of—hydrolysis in the presence of ketones	550

Purines 135,	3142
Purple of Cassius, rhythmic bands of	2261
Pyridine-3-carboxylic acid nitrate	2743
Pyrimidines, new methods of splitting—decompn. by ferrous salts	2972
Pyrocatechol	272
Pyrogallol, reaction with diphenic anhydride	3074
Pyrogallol aldehyde	2377
Pyrogallolbenzein	2995
Pyromucic acid, and Et ester	
Pyromucylhydroxamic acid, ketene and	520
QUANTUM theory, Origin and Development of the (Planck, book rev.)	1340
Quinine, partial and consecutive reactions in the photosensitive system: sulfate	
of, chromic and sulfuric acids	
Quinoidation, in the triarylmethyls	
Quinol	
Quinones, reduction potentials of	2194
	0.400
RADICALS, formation of free, by reduction with vanadous chloride	
Radio elements, intern. table of the, and their consts	870
Radon, solubilities of, 688; chem. action produced by	
Rape oil, test for	129
Rare earths, 614; absorption spectra	
Rays, new type of	
α-Rays, detn. of the mean effective path of, in small spheres, 2585; characteristics	
of the $\alpha$ -ray bulb as a source of ionization	
Reactions, statistical theory of monomol., 606; bimetallic electrode system ap-	
plied to neutralization	715
C ₂ H ₄ and H in the presence of metallic Cu, 1196, 2235; measurement of, and	
the temp. coeff. of, 1401; in concd. soln. and the mechanism of the inversion of sucrose, 1580; influence of neutral salts on the temp. coeff. of, 1896; temp.	
coeff. of photochem	
Recovery, in Relation to Cond. and Permeability (Osterhout, book rev.)	
Reduction, electrochem. method of studying irreversible org., 1047; Pt oxide as a	1001
catalyst in the, of org. compds., 1071, 2171, 3029; catalytic, of nitro compds.,	
1281, 2144; potentials of quinones, 2194; formation of free radicals by, with	
vanadous chloride, 2466; in the Animal Body (Dakin, book rev.)	2145
Relativity, Theory of General, and Gravitation (Silberstein, book rev.)	
Rennin, comparison between the chem. and physiol. characteristics of pepsin and	249
Resodiacetophenone, and benzidine	526
Resorcinol, 270; ethers of, 528; soly. relations of, 635; condensation of diphenic	020
anhydride with, 1030; production of imido thiol esters by the condensation	
of thiocyanates with, 1744; condensations of aldehydes with, 2984; reaction	
with diphenic anhydride, 3074; reaction with diphenyleneketone-4-carboxylic	
acid, 3075; reaction with fluorenone and bromination of condensation prod-	
ucts of	3076
Resorcinolbenzein.	
Resorcinol bis(&aminobutyl) ether, 535; decompn. of, hydrochloride by heat	
Resorcinol bis-γ-(n-amylaminopropyl) ether dihydrochloride	
Resorcinol bis(bromoethyl) ether	531

Resorcinol bis- $(\gamma$ -bromopropyl) ether	532
Resorcinol bis( $\gamma$ -cyanopropyl) ether	535
Resorcinol bis( $\gamma$ -iodopropyl) ether	533
Resorcinol bis(p-nitrobenzoyl-mono-δ-aminobutyl) ether	536
Resorcinol bis(n-propyl) ether	534
Resorcinolethein	2993
Resorcinolfurfurein	2994
Resorcinol-1'-hydroxybenzein	2991
Resorcinol-p-hydroxy-m-carboxybenzein	2994
Resorcinol-3-methoxybenzein.	2995
Resorcinol-2'-methoxy-3'-hydroxybenzein	2992
Resorcinolphenetoleazobenzeinsulfonic acid.	
Resorcylaldehyde	2376
β-Resorcylic acid, Me and Et esters	1751
β-Resorcylic-acid-benzein	2994
Rhus Dermatitis, from Rhus toxicodendron, radicans and diversiloba (McNair,	2110
book rev.)	
Rubber, action of SeOCi2 on pure	1800
SALICYLALDEHYDE, Hg derivs. of	1330
Salicylic acid	
Salts, factors influencing compd. formation and soly. in fused mixts. of, 963; soly.	
of KClO ₄ in, solns. and the corresponding activity relations, 2653; surface	
energy of several, 2658; ionization of vapors of, 2803; equil. in solns. contg.	
mixts.of	2935
Samarium, absorption spectrum of	910
Santonin, new sources of	1941
Science, Beiträge zur Geschichte der (von Lippman, book rev.)	2001
Selenic acid, refractive index of	29
Selenious acid, refractive index of	29
Selenium, at. wt. of, 568; electrometric titration of, in the presence of Te, Fe and	
Си	933
Selenium compounds, org	238
Selenium oxychloride, solubilities of certain metallic chlorides in, 1233; action	
upon ethylene, propylene, butylene and amylene, 1795; action on pure	
rubber, 1800; action on various metals and metallic oxides	
Selenophenes, synthesis of diaryl	238
Semicarbazides, behavior at elevated temps	3008
α-Semicarbazidobenzoylpropionic acid, Me ester, semicarbazide of, 231; Me	
ester, 232; Et ester, semicarbazide.	234
Semicarbazidomethylphenylpyrazolonecarboxylic acid, Me ester of, 233; Et ester	
of	235 3001
Semicarbazones, reduction of	2001
Silicic acid, effect of light and H-ion concn. on the formation of colloidal Au in,	0594
gel, 2261; sols	2534 2092
Silver chromate, surface energy of	
Silver indide, photographic sensitiveness of	
Silver oxide, action of SeOCl ₂ on	
Silver perchlorate, reaction between I and	
Soap, emulsions of mineral oil with, and water—interfacial film	
Sodium, at wt of 567; reactions with org. substances in liquid NH ₃ soln., 768;	

action on phenyl halides in liquid NH ₃ , 779; reduction of nitrobenzene by,	
in liquid NH3, 1780; sepn. and detn. of K and, 2072; vapor pressure of, 2325;	
displacement of metals from solns. of their salts by less electropositive ele-	
ments—replacement of, and K by Mg and Al	2788
Sodium alloys, correction to the fp. diagram of, with Pb	
Sodium amide, phase relations in the system K amide	
Sodium ammonoaluminate	
Sodium anilide	
Sodium arsenite, titration of solns. of permanganate and	
Sodium carbonate, equil. in system, H ₂ O and the chlorides and carbonates of Na	1010
and K, and in the system, H ₂ O and the sulfates and carbonates of Na and K.	2025
Sodium chloride, transference numbers of Na and K in mixed chloride soln., 1121;	2000
ionization const. for, 2804; soly. of CoNH ₃ salts in, solns., 2906; equil. in system	
	อดอธ
H ₂ O and the chlorides and carbonates of Na and K	
Sodium diphenylamide	784
Sodium ion, transference numbers of Na and K in mixed chloride soln	1121
Sodium sulfate, heat of coagulation of Fe ₂ O ₃ hydrosol with, 311; dissociation press-	
ure of hydrate of, 349; soly. of CoNH ₃ salts in, solns., 2906; equil. in the	200=
system, H ₂ O and the sulfates and carbonates of Na and K	
Sodium thiosulfate, standardization of, 1359; stability of, solns	
1-Sodiumthiosulfate-mercurimethyl-1,2-dihydrobenzofuran	
1-Sodiumthiosulfate-mercurimethyl-4-methyl-1,2-dihydrobenzofuran	
Soils, nature of the acidity of the colloidal clay of acid	
Solidification, curves of binary systems	1727
Solubility, 2828; relations in mixts. contg. polar components, 633; relations of	
certain gases, 682; factors influencing, in fused salt mixts., 963; mutual, of	
liquids (I) mutual, of Et ₂ O and water (II) of water in C ₆ H ₆ , 1143; lecture	
	2479
Solutions, design and use of conductance cells for non-aq., 1692; soly. of KClO ₄ in	
salt, and the corresponding activity relations, 2653; metallic, 2828; equil. in,	
contg. mixts. of salts	
Solvents, effect of the, on the reduction potentials of certain benzoquinones	
Soy beans, amino acids of	815
Specific gravity. See Density.	
Specific heats, evidence from the, of glycerol that the entropy of a glass exceeds	
that of a crystal at the abs. zero, 93; of polyatomic gases at low temps., 874;	
entropy of diatomic gases and rotational	2277
Spectra, absorption, of rare earths, 907; absorption, of nitrosylsulfuric acid and of	
the complex compds. of CuSO4 and of FeSO4 with NO, 1863; absorption, and its	
relationship to color	2420
Spruce, mannose from white, cellulose	1008
Standard solutions, for iodimetry	1358
Steady state	1251
Steel, detn. of S in, 649; detn. of Mn in	1615
Strontium chloride, dissociation pressures of hydrates of	349
Strontium sulfate, surface energy of	2661
Sucrase. See Invertase.	
Sucrose, mechanism of the inversion of, 1580; effect on the activities of certain	
ions	1627
Sugars, fluoroacetyl derivs. of, 833, 2381; electrometric titration of reducing,	1 1
1043; revision of Rosanoff's diagram of the aldose, 1273; contd. in tuberculinic	
acid	1823

Sulfarsphenamine Sulfates, vapor pressures of certain hydrated metal. Sulfides, electrometric detn. of S in sol. Sulfonyl halides, reaction with p-Hg ditolyl. Sulfur, forms of, in coke—physicochem. study of the, held by C at high temps., 1;	578 645
simultaneous detn. of, and halogen in org. compds., 255; comparison of the normal boiling temps. of undesiccated, as measured by the dynamic and the static methods, 327; soly. in the persulfides of H, 601; electrometric detn. of, in sol. sulfides, 645; detn. in steel, 649; detn. in org. compds., 1033; content of arsphenamine and its relation to the mode of synthesis and the toxicity, 1316; detn. of total, in biol. material, 1953; influence on the color of	
azo dyes, 2399; action on $p$ -toluidine in the presence of litharge Sulfuric acid, decompn. of $HCO_2H$ by, 477; partial and consecutive reactions in the	
photosensitive system: quinine sulfate, chromic acid and, 1891; soly. of I ₂ O ₅ in. Suprarenine. See <i>Adrenaline</i> .	108
Surface energy, soly. and, of CaSO ₄ , 2479; of several salts	
Synthesis, new type of	839 1727
TARTRAZIN, adsorbed moisture and water of crystn.in	1664
Technology, Beiträge zur Geschichte der (von Lippman, book rev.)	2001
Tellurium, volumetric detn. of	1423
Temperature, app. for working with gases at low, 332; coeff. of reaction velocity,	
1401; influence of neutral salts on the, coeff. of reaction velocity, 1896;	
of explosion for endothermic substances	2430
Terephthalaldehyde, derivs. and reactions of	526
Terpenes, effect of fuller's earth on	728
Tetraallyl-α-methyl glucoside	2700
Tetraarsenoacetic acid	3023
Tetrabromophenolsulfonephthalein	495
Tetrabromoquinone	480
o-(o-(1,3,6,8-Tetrabromo-2,7,9-trihydroxyxanthenyl)phenyl)benzoic acid, 9-lactone	
of	1032
Tetrachlorobenzoquinone	2207
1,1-Tetraethylammoniummercuric bromide	1764
Tetrahydrofuryl alcohol	3040
Tetrahydrofuryl-1-butanol-3	
Tetrahydrofuryl-1-butanone-3	
Tetrahydrofuryl-1-phenyl-3-propanol-3	
Tetrahydrofuryl-1-phenyl-3-propanone-3	
β-Tetrahydrofurylpropionic acid	
Tetrahydro-1,3,2-oxazones	
Tetrahydropyromucic acid, and Et ester	
Tetramethylammonium tetrachloroiodide	
Tetramethylammonium trichloroiodide	
1,4-Tetramethylene glycol, prepn. of, and partition of C ₂ H ₂ between ethylene glycol and	
Tetranitroaniline, soly. in org. solvents	
Tetraphenylmethane	
Tetryl, soly. in org. solvents.	
Thallium, at. wt. of, 571; heat of soln. of, in dil. Tl amalgams	

Thallium alloys, heat of soln. of Tl in dil. Tl amalgams	1455
Thermodynamics, third law of, 93; and the Free Energy of Chem. Substances	
(Lewis, Randall, book rev.)	1855
Thermostat, 579; low-temp	
Thiocyanates, production of imido thiol esters by the condensation of, with	
resorcinol or phloroglucinol	
Thiol- $\beta$ -resorcylic acid, Me ester monohydrate	
Thiol-2,4,6-trihydroxybenzoic acid, Me ester	
Thiophenes, synthesis of diaryl	
Thiosulfate ion, free energy of the	
Thio-p-toluidine, constitution and some new derivs. of	
Thulium, absorption spectrum of	
Thymol, synthesis from p-cymene	
Thymoquinone, 2201; amino and oximo derivs. of	
Tin, sepn. of As and, 1187; at. heat at low temps., 1413; action of SeOCl2 on, 2094;	
activities of Zn, Cd, Pb, Bi and, in their binary liquid mixts	
Tin compounds, equiv. conductance of Me ₃ SnCl in EtOH, 2624; conductance of	
Me ₃ SnCl in mixed solvents, 2946; compds. formed between alkyl tin halides	
and NH ₂ and the amines	3078
Tin tetraiodide, cryst. structure of	
Tissue, plant, effects of the method of desiccation on the carbohydrates of	439
Titanium, revision of the at. wt. of, 1228; detn. of	
Titanium tetrachloride, analysis of	
Titanous sulfate, electrometric titration of iodate, bromate, chlorate, ferricyanide	
with	
Titration, of solns. of permanganate and Na ₂ AsO ₃	
Toluene, adsorption of, vapor on plane glass surfaces, 63; reaction of nitrosyl	
chloride on, 1045; ternary system, acetone-water	
p-Toluenesulfinic acid, Na salt of	
ρ-Toluenesulfonyl iodide.	
o-Toluidine, dichloroacetate, 1995; trichloroacetate	
p-Toluidine, dichloroacetate, 1996; trichloroacetate, 1997; action of S on, in the	
presence of litharge	
3-o-Toluidino-4-carbethoxy-5-isoxazole	
3-p-Toluidino-4-carbethoxy-5-oxyisoxazole	
3-0-Toluidino-4-carbethoxy-5-oxypyrazole	
3-p-Toluidino-4-carbethoxy-5-oxypyrazole.	
2-p-Toluino-3-chloro-5-hydroxy-1,4-naphthoquinone	
Toluquinone	
β,p-Toluylacrylic acid, and Me ester	
β,p-Toluyl-α-chloropropionic acid	
$\beta, p$ -Toluyl- $\beta, \alpha$ -dibromopropionic acid	
p-Tolyl mercury compounds, prepn. of	
Transference numbers, moving boundary method for detg	
1,4,5-Triacetoxy-2,3-dichloronaphthalene	
Triarylmethyls, number of consecutive decolorizations of the, on oxidation, 204;	10.1
dissociation of N-pentamethylene (or N-piperidyl)-S-triarylmethyldithioure-	
thans with the formation of, 544; quinoidation in the	1765
Tribenzylcarbinol	276
Tribenzylsilicol.	276
Trichloroacetic acid, direct conversion of derivs. of dichloroacetic acid into derivs.	٠,٠
of, 1994; action of HgO on	2970
The state of the s	20,0

Trichloromethyldimethylcarbinol, ester of carbamic and carbanilic acid 2-Trichloromethyl-1,3-dioxolane-4-carbinol, and carbamic acid ester	478 479
Trichloromethylmethylcarbinol, ester of carbamic acid	
Trichloroquinone	2206
1,2-Triethylammoniummercuric bromide.	
1,4,5-Trihydroxy-2,3-dichloronaphthalene	
Trihydroxymethylanthraquinones	
o-(o-(2,7,9-Trihydroxyxanthenyl)phenyl)benzoic acid, 9-lactone of	
Trimethylacetic acid, mercuric salt	
Trimethyleneglycol, partition of acetylene between ethylene glycol, 1,2-propylene	110#
glycol, 2-methyl-2,4-pentanediol and glycerol and	2122
Trimethylethoxyammonium bromide	359
Trimethylethoxyammonium hydroxide	359
Trimethylethylene, reaction with NCl ₃	
Trimethylhydroxyammonium chloride	
Trimethylhydroxyammonium sulfate	358
Trimethyliodomethylammonium hydroxide	
Trimethylmethoxyammonium iodide	
Trimethyl stannyl chloride, equiv. conductance of, in EtOH, 2624; conductance	
of, in mixed solvents	
Trinitro-m-cresolates, and their explosion temps	2430
Trinitrophenylmethylnitramine. See Tetryl.	
Trinitrotoluene, soly. in org. solvents	44
Triphenylamine, m. p. of mixts. of diphenylamine and	
Triphenylcarbinol, 274; K deriv. of, and its use as a synthetic agent, 1965; re-	
duction of	
Triphenylchloromethane, action of K and of K triphenylmethyl on, 2760; action	2411
of Ca on	2761
Triphenylmethane, 276; and derivs., 273; action of metallic Na on	
Triphenylmethyl, 190, 207, 1765; spontaneous dissocn. of triphenylmethyl	
disulfide with the formation of, 1965; action of the alkali metals on, and	
its compds.	
Triphenylmethyl disulfide, spontaneous dissocn. of, with the formation of tri-	
phenylmethyl	1965
2,4,6-Triphenylpyrylium chloride, reduction of	2470
Trypsin, hydrolysis of collagen by	
Tryptophan, detn. of	
Tuberculinic acid, sugar contd. in	
Tuberculosis, Chemistry of (Wells, DeWitt, Long, book rev.)	
Tung oil, test for	
1 yrosylalalillenydalitoiii	040
UNSATURATION, and mol. compd. formation	1433
Uracil, reduction to hydrouracil	
Uranium, quant. sepn. of Be and	395
Urea, synthesis with urease, 501; action of urease in the decompn. of, 505; de-	
arrangement, 1816; Chemistry of-Theory of its Constitution, and of the	
Origin and Mode of its Formation in Living Organisms (Werner, book rev.)	2007
Urease, synthesis of urea with, 501; action in the decompn. of urea, 505; relation-	

3210 INDEX

ship between the chem. structure of certain compds. and their effect on activity of	78, 3142 475 rith	5
VALEROLACTONE, mechanism of the formation of	84 2466 17; 2323 y of ant.	4 3 3
Water, equil. in the systems, NiCl ₂ , CoCl ₂ , CuCl ₂ —HCl, 663; apparent deviate from Henry's law for the system, NH ₃ , 915; mutual soly. of Et ₂ O and soly. in C ₆ H ₆ , 1143; precision measurement of the compn. of the comboiling mixt. of HCl and, 1220; adsorbed moisture and water of crystan certain common dyes, 1657; ternary system, toluene—acetone, 2555; equil system, H ₂ O and the chlorides and carbonates of Na and K and in system H ₂ O and the sulfates and carbonates of Na and K	d— ust	7 9 1
XANTHYLIUM chloride, reduction of  Xylenes, sepn. of  p-Xyloquinone	83	0
YTTRIUM, at. wt. of	56	9
ZINC, sepn. of Fe and Al from, 676; vapor pressure of, 2326; diffusion of through, 2860; activities of Cd, Sn, Pb, Bi and, in their binary liquid mixts Zinc chloride, antiseptic action of the, salt of aniline.  Zinc oxide, extn. of Ge from Ge-bearing.  Zinc sulfate, dissociation pressures of hydrates of.  Zirconium (Venable, book rev.).  Zirconium compounds (Venable, book rev.).	286 310 138 34	)6 30 19 57

## **PROCEEDINGS**

OF THE

# American Chemical Society

FOR THE YEAR 1923

EASTON, PA. ESCHENBACH PRINTING COMPANY 1923

## **PROCEEDINGS**

### Contents

### January

Directors' Minutes	
Council	Ł
Members Elected Between November 15 and December 15, 1922	Ł
Meetings of the Sections:	
Ames Section	7
Blood Chemistry and the Diagnosis of Disease, Chi Che Wang.	
California Section 8	3
The Relation of Chemistry to Dentistry, Guy S. Millberry.	
Chicago Section.	3
Chemistry and the Motion Picture, C. E. K. Mees. Louis Pasteur, Edwin	
O. Jordan.	
Cincinnati Section 8	3
Some Novel Aspects of Colloidal Protection, Terome Alexander.	
Colorado Section	3
Columbus Section	3
Connecticut Valley Section	
Industrial Spectrum Analysis, C. H. Davis.	
Cornell Section.	3
The Cryoscopy, Refractometry, and Electrical Conductivity of Milk, F. E.

Report of the Secretary of the American Chemical Society for the Year 1922 Report of the Editor of the Journal of the American Chemical Society for the Year	13
1922	17
Report of the Editor of Chemical Abstracts for 1922	18
Report of the Editor of Industrial and Engineering Chemistry	21
Council	23
Members Elected between December 15, 1922 and January 15, 1923	23
Meetings of the Sections:	
California Section	30
Central Texas Section	30
Chicago Section	30
Sunlight as a Factor in the Vitamin Problem, Mrs. Elizabeth Miller Koch.	
Cincinnati Section	30
Some Aspects of Industrial Poisoning, Carey Pratt McCord. The Nature of Heavy-Metal Poisoning and its Relief, Robert A. Kehoe.	
Cleveland Section	30
The Rubber Plantation Industry in the Far East and the Preparation of Rubber for the World's Market, George Oenslager.	
Connecticut Valley Section	30
Some Aspects of the Sizing of Paper, William P. Ryan.	
Cornell Section	31
Delaware Section.	31
	31
Detroit Section	91
Eastern New York Section	31
Indiana Section.  Progress of Science in Food Preservation, C. E. Stone. The Manufacture and Analysis of Evaporated Milk, W. L. Clark. The Value of Industrial Research, E. R. Weidlein.	31
Iowa Section	31
Kansas City Section	31
The Composition of the Atom, H. P. Cady. The Interpretation of the Analysis of Soap Materials, Wm. J. Reese.	
Lehigh Valley Section	32
Louisville Section.	32
Maine Section.	32
Chemistry of Fuel, Heat and Light (Illustrated), C. A. Brautlecht.	
Maryland Section	32
Trivalent Titanium in Analysis, W. M. Thornton. Soil Colloids and the	
Theory of Adsorption, Neil Gordon. A Laboratory-Made Vacuum Oven, W. B. D. Penniman.	
Midland Section	32
Electrolytic Caustic Cells, Ralph Hunter, Transformations, Uses, Losses,	Ju

and Costs of the Heat Energy of Coal in the Dow Chemical Plants, Roy Osmun.	
Milwaukee Section	32
New Haven Section	32
Some Aspects of the Smoke Problem, R. E. Swain.	00
New York Section	32
Northeastern Section	33
Philadelphia Section	33
Pittsburgh Section	33
Manufacture and Use of Enamel-Lined Apparatus, Emerson P. Poste.  Manufacture and Properties of Oven-Glass Cooking-Ware, Ralph F.  Brenner. Manufacture of Electrical Porcelain, E. H. Fritz.	
Puget Sound Section	33
Purdue Section	33
Soil Toxicity, R. H. Carr. Water, The Most Peculiar Liquid, F. O. Anderegg.	
Rochester Section	33
Motion Picture Photography for the Amateur, C. E. K. Mees.	
Sacramento Section	33
Saint Louis Section	33
Beyond the Microscope, Gerald L. Wendt.	
Southeast Texas Section	34
South Jersey Section	34
Vitamins from a Historical and Chemical Standpoint, W. S. Calcott. Vitamins from a Medical Standpoint, R. S. Sutherland. Recent Developments in the Theory and Practice of Distillation, W. A. Peters, Jr.	
Syracuse Section.  Vitamins, R. Adams Dutcher. The Manufacture of Gas, G. I. Vincent.	34
Perfumes, Natural and Synthetic, M. T. Bogert. Toledo Section	34

### June

Council	85 85
Meetings of the Sections: Chicago Section	86
The Theory of Color Production in Dyes, Prof. Julius Stieglitz.	
Cincinnati Section	86
Colorado Section	86 86
Cornell Section	87
Delaware Section	87
Detroit Section	87
Hawaiian Section	87
Indiana Section	87
Iowa Section	87
Kansas City Section	87
Lehigh Valley Section	87
Lexington Section	88
Maine Section.  Application of the Electron Theory of Valence to Organic Chemistry, F. F. Oplinger.	88
Michigan Agricultural College Section	88
Milwaukee Section	88
Minnesota Section	88
Nashville Section.  Problems in the Manufacture of Sweet Potato Products, J. E. Copenhaver.  Progress of a Study of the Preparation of an Organic Compound by Electricity, B. F. Armendt.	88

Nebraska Section	88
Radium and Radioactivity, H. P. Cady.	-
North Carolina Section.	88
Chemical Industries in North Carolina, F. C. Vilbrandt. The Chlorination	-
of Juglone in Hot Acetic Acid, A. S. Wheeler and J. L. McEwen. The	
Bromination of 2-Amino-p-xylene, A. S. Wheeler and E. W. Constable.	
The Schohl and Pedley Method for Determination of Calcium Compared	
with McCrudden's Volumetric Method, J. O. Halverson and L. M. Dixon.	
A New Ketone Reagent: p-Bromophenylsemicarbazide, A. S. Wheeler and	
J. A. Bender. The Constitution of the Dichlorohydroxyethylidene-bis-	
nitroanilines, A. S. Wheeler and S. C. Smith. Problems of the Chemist in	
the Textile Industry, K. W. Franke. A Vacuum Gage, M. L. Hamlin.	
A Peculiar Reaction between Dichloroacetic Acid and Aromatic Amines,	
A. S. Wheeler and S. C. Smith. A Peculiar Phenomenon of the Bunsen	
Burner, H. B. Arbuckle. A Suggestion in Regard to Some Problems Relat-	
ing to the Hydration of Ions, E. E. Randolph.	
Northeastern Section	89
The Chemical and Physical Aids to Diagnosis, Allan Winter Rowe. Some	00
Chemistry of the Insect World, Gorham W. Harris.	
Omaha Section	89
The Omaha Plant, American Smelting and Refining Co., as an Industry,	
A. E. Hall. Chemistry as Applied to Lead Bullion Refining, B. N. Kil-	
bourn. Chemistry as Applied to the Smelting of Non-Ferrous Metals,	
V. T. Price. The Chemistry and Uses of Bismuth, J. O. Betterton. The	
Laboratory and Assaying Department. Its Purpose and Relation to the	
Plant, E. Wurgler.	
Philadelphia Section	89
Structure, Henry Green.	
Pittsburgh Section	89
The Urologist or Water Caster in Art, Jacob Rosenbloom.	
Purdue Section	89
The Sense of Smell, Ellwood Hendrick. The Ammonia System of Com-	
pounds, E. C. Franklin.	
Rochester Section	89
Soap and Glycerine, Lincoln Burrows. The Alchemist, Paul D. Foote.	
Saint Louis Section	90
Some Modern Conceptions of Alcoholic Fermentation, John R. Eoff, Jr.	
Fuel Saving in Modern Gas Producers and Industrial Furnaces, W. B.	
Chapman. A Trip to Cuba, Panama and Costa Rica, Paul V. Bunn.	
Sacramento Section	90
South Jersey Section.	90
The Acceleration of Vulcanization in Rubber, Winfield Scott.	
Syracuse Section	90
Research at the University of Amsterdam, A. F. Holleman.	
Toledo Section	90
Chemistry as Applied to the Insecticide Industry, O. F. Hedenburg.	223
University of Illinois Section	90
The Ammonia System of Compounds, President E. C. Franklin. The	
Development of our Organic Chemical Industry, Dr. L. F. Nickell. Home	
Remedies—Their Claims Versus Composition, Dr. P. N. Leach. Some	
Reactions in the Corona Discharge and the Temperature Corresponding	
to Equilibrium, Gerald L. Wendt. Electrolytic Polarization, H. P. Cady.

## Proceedings

#### DIRECTORS' MINUTES

The Directors of the American Chemical Society met at the Chemists' Club, New York City, at 3 P.M., Friday, November 24th, with President Edgar F. Smith in the chair and the following Directors present: W. D. Bancroft, A. D. Little, H. P. Talbot, John E. Teeple, M. C. Whitaker and Charles L. Parsons.

It was voted that the Secretary should continue his present policy of sending the final programs of meetings only to members in the immediate vicinity of the meeting, to corporation members, to the Councilors, to the chairmen and secretaries of local sections, and to those who make written request therefore of the secretary previous to the meeting.

The Secretary was authorized to issue a charter for a local section to be formed at Akron, Ohio, covering territory immediately contiguous thereto, such as Summit County, as soon as the properly signed petition and waiver of jurisdiction is received therefor.

It was voted to authorize the Treasurer to make loans and pledge the collateral of the Society therefor to an amount not exceeding Forty Thousand Dollars annually when in his judgment it is necessary to do so to meet the necessary current expenditures of the Society.

The Treasurer reported that he had borrowed \$25,000 at the Farmers Loan & Trust Co. on Nov. 9, 1922 to meet current expenses.

It was voted that the Editor of the Journal of Industrial and Engineering Chemistry be authorized to re-lease for one year the premises now occupied by him.

It was voted that special reprints, such as theses, be handled through the same channels as the regular reprints and billed from the Secretary's office.

It was moved that in the budget voted to the various editors they be limited not simply to the funds allotted, but also to the number of pages indicated.

It was voted to authorize the Editor of the Journal of Industrial and Engineering Chemistry and the Director of the News Service to issue a twelve-page news edition of that Journal to be separately paginated and to be published on the 10th and 20th of each month.

On recommendation of the Committee to Consider the Question of a non-Society Employment Bureau, and in furtherance of the vote of the Council favoring a clearing house for employment information, as printed on page 96 of the Proceedings for 1922, it was further voted that such part of four pages of each issue of the News Edition as might be needed should be used to furnish such information. The Directors added \$2100 to the budget to cover this service and deducted the cost of printing the advertising pages now devoted to "classified advertisements." The Directors understood that these pages would be used for announcements of positions open and situations wanted by members of the Society. In general, these announcements are to be supplied by the employment committees of local sections and from educational institutions. Under proper limits to be formulated, the pages will also be open to any paid member of the Society seeking employment. It shall, however, be definitely printed in each issue that the Society assumes no obligation as to the qualifications of employees or responsibility of employers.

The following budget was then unanimously adopted for 1923:

#### ESTIMATED INCOME

	Budget	Budget
	1922	1923
Dues	\$175,000.00	\$175,000.00
Subscriptions	21,000.00	22,000.00
Back Numbers	5,000.00	5,000.00
Reprints	1,800.00	2,500.00
Postage	4,000.00	4,000.00
Advertising	86,250.00	94,500.00
Interest	6,000.00	5,400.00
	0,000.00	0,100.00
Total	\$299,050.00	\$308,400.00

	\$ 1,200.00	\$ 1,200.00
Scientific Monographs:		
Salary	\$ 1,000.00	\$ 1,000.00
Expenses	60.00	60.00
	\$ 1,060.00	\$ 1,060.00
Technological Monographs:*(d)		
Salary	\$ 1,000.00	
Expenses	25.00	
	\$ 1,025.00	
Advertising:		
Printing Advertisements	\$ 38,243.00	\$ 33,000.00
BACK NUMBERS	2,000.00	1,500.00
Local Sections	8,500.00	8,500.00
Incidentals	1,500.00	2,000.00
General Meetings	2,000.00	2,000.00
Tables Physical Constants	500.00	500.00
Metric System Committee	100.00	
Grand Total	\$300,100.00	\$311,200.00

- *(a) The 1922 budget as printed was on a 10% reduction of printed pages for each journal from the amount requested by the editors. This 10% was restored some three months later, so that the 1922 budget in the case of each journal is less than actual expenditures. Also, approximately \$3200 spent for Formula Index for 1922.
- *(b) The extra cost of the News Service Edition of *Industrial and Engineering Chemistry* will be largely paid for by extra advertising in 1923 and is expected ultimately to be a source of actual revenue.
- *(c) The committee of the Council originally recommended \$5,000 for this item, but changed it to \$2,100 in view of the facilities offered by the News Edition.
- *(d) Expenses of Technological Monographs in 1923 are carried in the *Industrial* and Engineering Chemistry budget.

Charles L. Parsons, Secretary

#### COUNCIL

The following communication was sent to the Council on November 25th:

#### AMERICAN CHEMICAL SOCIETY

November 25, 1922

Council of the American Chemical Society:

Gentlemen: The following members have been duly nominated for the offices indicated for the years 1923 and 1923-1925. Kindly check your choice with an X and return the ballot on or before December 16th.

Kindly note that by vote of the Council the names are arranged in alphabetical order and not in the order of the nominating vote.

Very truly yours,

CHARLES L. PARSONS, Secretary

President.—1923 only (one to be chosen) (alphabetically arranged): E. C. Franklin, James F. Norris, S. W. Parr, Charles L. Reese.

Directors.—1923-1925, inclusive (two to be chosen) (alphabetically arranged): Wilder D. Bancroft, William Hoskins, John Johnston, S. W. Parr.

Councilors-at-Large.—1923-1925, inclusive (four to be chosen. Ballot is void unless four are voted for) (alphabetically arranged): Roger Adams, C. A. Browne, H. N. Holmes, G. N. Lewis, Ralph H. McKee, Wm. McPherson, C. S. Miner, S. W. Parr.

The returns of this ballot were counted on the evening of December 16th by a committee consisting of L. I. Shaw, H. E. Howe and Charles L. Parsons, and the following officers were elected:

President: E. C. Franklin.

Directors: Wilder D. Bancroft, William Hoskins.

Councilors-at-Large: Roger Adams, G. N. Lewis, Ralph H. McKee, Wm. Mc-Pherson.

Charles L. Parsons, Secretary

#### MEMBERS ELECTED BETWEEN NOVEMBER 15 AND DECEMBER 15, 1922

#### CORPORATION MEMBERS ELECTED

Boston Rubber Shoe Co., 183 Commercial St., Malden, Mass. Fansteel Products Co., Inc., North Chicago, Ill.

#### MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G. St., N. W., Washington, D. C.)

#### AMES SECTION

On November 14, Chi Che Wang, of the Nelson-Morris Institute of Medical Research in Chicago, spoke before the Section on "Blood Chemistry and the Diagnosis of Disease."

H. M. McLaughlan, Secretary

#### CALIFORNIA SECTION

The 135th regular meeting of the Section was held on November 24, when Guy S. Millberry, professor of dental chemistry and dean of the College of Dentistry of the University of California, addressed the members on the subject, "The Relation of Chemistry to Dentistry."

L. H. Duschak, Secretary

#### CHICAGO SECTION

The November meeting of the Section was addressed by C. E. K. Mees, of the Eastman Kodak Company. His subject was "Chemistry and the Motion Picture."

On December 15, Edwin O. Jordan of the University of Chicago, gave an address on "Louis Pasteur." S. L. Redman, Secretary

#### CINCINNATI SECTION

The 254 regular meeting of the Section was held on December 13, when Jerome Alexander gave an address on "Some Novel Aspects of Collodial Protection."

C. H. LUND, Secretary

#### COLORADO SECTION

On November 22, John B. Eekley, of the University of Colorado, addressed the members of the Section.

RUTH B. VERTREES, Secretary

#### COLUMBUS SECTION

At a meeting of the Section, held on November 21, 1922, the following officers for 1923 were elected: G. O. Higley, chairman; C. W. Foulk, vice-chairman; W. G. France, secretary-treasurer; W. L. Evans and C. E. Boord, councilors.

EDWARD MACK, JR., Secretary

#### CONNECTICUT VALLEY SECTION

The regular monthly meeting of the Section occurred on December 9, when C. H. Davis, of the American Brass Company, spoke on "Industrial Spectrum Analysis."

PAUL SEREX, JR., Sccretary

#### CORNELL SECTION

On December 14, F. E. Rice addressed the Cornell Section, his subject being "The Cryoscopy, Refractometry, and Electrical Conductivity of Milk."

F. E. HANCE, Secretary

#### DELAWARE SECTION

The regular meeting of the Section was held on December 20. W. K. I,ewis, of the Massachusetts Institute of Technology, spoke on "Combustion."

J. E. BOOGE, Secretary

#### DETROIT SECTION

The opening meeting for the fall season of the Section was held on November 15, when C. E. K. Mees of the Eastman Kodak Company, spoke on "The Chemistry of the Motion Picture."

S. R. Wilson, Secretary

#### EASTERN NEW YORK SECTION

At the regular meeting of the Section, held on November 17, Eugene C. Bingham, of Lafayette College, Easton, Pa., spoke on "Fluidity and its Relation to Other Physical and Chemical Properties."

The following officers were elected to take office January 1, 1923: G. R. Fonda, chairman; Arthur Knudson, vice-chairman; Edward H. Darby, secretary-treasurer; Saul Dushman and Edward Ellery, councilors; and G. M. J. Mackay, Mrs. M. R. Andrews and W. P. Davy, executive committee,

On December 14, Howard D. Clayton, of Cluett-Peabody, spoke to the members of the Section, his subject being "Textile Chemistry."

E. H. Darby, Secretary

#### HAWAIIAN SECTION

The annual meeting of the Section was held on November 15, when the present officers were reëlected for the ensuing year. A paper entitled, "A Study of Jelly Making as Concerns Hawaiian Fruits," was read by John C. Ripperton.

RONALD Q. SMITH, Secretary

#### IOWA SECTION

The regular monthly meeting of the Section was held on November 22. A paper entitled "Compressed Gases and their Uses," was delivered by A. J. Russell, of the Bettendorf Oxygen Hydrogen Co.

L. Charles Raiford, Secretary

#### KANSAS CITY SECTION

On November 22, R. F. Knappen read a paper before the Section, the subject being "Some Relations of Chemistry to Geology."

L. E. CLARK, Secretary

#### LOUISVILLE SECTION

The Section held a meeting on November 15, when C. K. Francis, of the Cosdon Company, Tulsa, Oklahoma, spoke on "Petroleum Chemistry." The following officers for 1923 were elected: C. E. Bales, chairman; T. J. Bosman, vice-chairman; C. E. Geiger, secretary-treasurer; A. W. Homberger, councilor.

C. E. Geiger, Secretary

#### MAINE SECTION

At the meeting of the Section, held on November 10, the following officers were elected for 1923: C. A. Brautlecht, president; J. M. Bartlett, vice-president; N. E. Woldman, secretary-treasurer.

On December 8, B. F. Brann addressed the Section on the subject "Nitrogen Fixation."

N. E. Woldman, Secretary

#### MARYLAND SECTION

The 60th meeting of the Section occurred on November 24, and was a joint meeting of the Maryland and Washington, D. C. Sections. In the afternoon an inspection of the American Sugar Refinery, at Locust Point, Md., was made, and in the evening Carl F. Huttlinger, superintendent of the American Sugar Refinery, addressed the meeting on "The Process of Refining Sugar."

The following officers for 1923 have been elected: S. T. Powell, chairman; Carl Haner, Jr., vice-chairman; Adolph Harvitt, secretary-treasurer; A. E. Marshall, A. A. Backhaus and Neil E. Gordon, councilors; J. C. W. Frazer, M. D. Scott, W. A. Taylor, A. H. Warth, W. B. D. Penniman, and J. H. Wolfe, executive committee.

ADOLPH HARVITT, Secretary

#### MICHIGAN AGRICULTURAL COLLEGE SECTION

On November 10, W. Lee Lewis, of Northwestern University, addressed the meeting of the Section, his subject being "The Organic Chemist."

The Local Section held its annual banquet on the evening of December 8. Howard B. Lewis, of the University of Michigan, spoke on "Recent Developments in the Study of the Role of Proteins in Nutrition."

E. F. ELDRIDGE, Secretary

#### MILWAUKEE SECTION

The following officers have been elected for 1923: C. H. Hall, chairman; C. N. Davidson, vice-chairman; A. A. Chambers, secretary; L. E. Power, treasurer; R. N. Bauer and C. R. McKee, councilors.

On November 17, W. Lee Lewis, of Northwestern University, addressed the members of the Section on the subject, "The Organic Chemist at Work."

O. A. CHERRY, Secretary

#### MINNESOTA SECTION

The 104th regular meeting of the Section occurred on November 27, when Victor Lenher, of the University of Wisconsin, gave a lecture on "Selenium Oxychloride."

On December 13, F. J. Alway, gave a paper on "The Agricultural Uses of Peat," and C. I. Wallfred, a paper on "Peat as an Industrial Fuel."

L. M. HENDERSON, Secretary

#### NEBRASKA SECTION

The 106th meeting of the Section occurred on November 28. The subject of the meeting was "Unpublished Researches from the University of Nebraska Chemical Laboratory," presented by Fred W. Upson, Ernest Anderson and T. J. Thompson.

S. B. Arenson, Secretary

#### NEW HAVEN SECTION

A meeting of the Section was held on December 5. Following a dinner in the evening, S. K. Becker of the U. S. Aluminum Company, spoke on "Aluminum Casting Alloys."

BLAIR SANTON, Secretary

#### NORTHEASTERN SECTION

The 180th meeting of the Section occurred on December 8, with the following program: "Petroleum Research," by C. O. Johns, of the Standard Oil Company; and "Recent Developments in Catalysis," by H. W. Underwood, Jr., of the Massachusetts Institute of Technology.

In lieu of the regular January meeting of the Section, a smoker to the visiting members of Section C of the American Association for the Advancement of Science, was given on December 29.

E. B. MILLARD, Secretary

#### PHILADELPHIA SECTION

On November 17, W. D. Collins of the U. S. Geological Survey, delivered a lecture before the members of the Section, his subject being "Hardness of American Water Supplies."

The regular monthly meeting of the Section was held on December 21, when John H. Muller, of the University of Pennsylvania, gave a lecture on "Germanium."

J. HOWARD GRAHAM, Secretary

#### PITTSBURGH SECTION

The 182nd meeting of the Section was held on November 16. The paper of the evening was by C. M. Johnson, on "Some Corrosion-Resisting Steels."

On December 21, W. M. Corse addressed the members, his subject being "The Manufacture and Properties of Nickel."

E. S. STATELER, Secretary

#### PUGET SOUND SECTION

The regular monthly meeting of the Section was held on November 23, when E. Z. Lynn, of the College of Pharmacy, University of Washington, read a paper on "The Manufacture of Zinc and Barium Products."

The following officers have been elected for 1923: Thomas G. Thompson, chairman; A. G. Bissell, vice-chairman; R. W. Ellison, secretary; G. C. Howard, treasurer; and H. K. Benson, councilor.

R. W. Ellison, Secretary

#### PURDUE SECTION

The Section held a meeting on November 16, at which time C. E. K. Mees of the Eastman Kodak Company, gave an illustrated lecture on "Chemistry and the Motion Picture."

MARGUERITE G. MALLON, Secretary

#### RHODE ISLAND SECTION

At the meeting of the Section, held on November 24, Augustus H. Fiske, chief chemist of the Rumford Chemical Co., spoke on chemical problems with which he has been connected.

A meeting of the Section was held on December 22, when A. N. Dana, of Yale University, lectured on "Some of the Very Apparent Advantages of Dyeing in Wound Form."

Nelson Barlow, Secretary

#### ROCHESTER SECTION

The 144th regular meeting of the Section occurred on November 20, when W. K. Lewis, of Massachusetts Institute of Technology, spoke on "Combustion."

The 145th regular meeting of the Section was held on December 4. Thomas Midgley, Jr., of the General Motors Research Corporation, gave a paper on "A Elementary Discussion of Research."

B. M. Billings, Secretary

#### SAINT LOUIS SECTION

Short papers, as follows, were presented at the meeting of the Section, held on December 4: "A New Form of Melting Point Apparatus," by H. A. Bell; "Some Difficulties in the Qualitative Detection of Morphine," by B. H. St. John; and "The Customs Chemist," by Fred West.

At this meeting the following officers for 1923 were elected: P. A. Shaffer, chairman; R. R. Matthews, vice-chairman; H. A. Carlton, secretary; B. H. St. John, treasurer; A. C. Boylston, C. W. Cuno and E. J. Sheppard, councilors.

H. A. Carlton, Secretary

#### SAVANNAH SECTION

At the first fall meeting of the Section, held on November 2, Herbert S. Bailey gave an extensive report on the Pittsburgh meeting. The following officers for 1923 were elected: Philip McG. Shuey, chairman; John N. Everson, vice-chairman; Herbert P. Strack, secretary; and Herbert S. Bailey, councilor.

Herbert S. Strack, Secretary

#### SOUTHERN CALIFORNIA SECTION

On December 14, Richard C. Tolman, of the California Institute of Technology, addressed the meeting of the Section, his subject being "Modern Ideas as to the Structure of the Atom."

MARK WALKER, Secretary

#### SYRACUSE SECTION

The 164th regular meeting of the Section was held on December 8. Horace C. Porter spoke on "Coal Carbonization and the World's Fuels." W. B. Hicks, Secretary

#### UNIVERSITY OF ILLINOIS SECTION

The regular meeting of the Section occurred on November 21. W. H. Rodebush of the University of Illinois, spoke on "The Production of Helium for Military Purposes." The following officers for 1923 were elected at this meeting: J. H. Reedy, chairman; A. M. Buswell, vice-chairman; D. T. Englis, secretary; Edith Nason, treasurer; Roger Adams and B. S. Hopkins, councilors.

D. T. Englis, Secretary

#### UNIVERSITY OF MICHIGAN SECTION

On December 14, H. B. Lewis, of the University of Michigan, addressed the members of the Section, his subject being "Some Recent Advances in the Role of Proteins in Nutrition."

C. C. Meloche, Secretary

#### VIRGINIA SECTION

The 53rd regular meeting of the Section occurred on November 10, when Robert N. Pease, of the University of Virginia, addressed the members on the subject "Recent Developments in Contact Catalysis."

W. G. CROCKETT, Secretary

#### WASHINGTON, D. C. SECTION

The 335th meeting of the Section occurred on November 24, and was a joint meeting, in Baltimore, Md., with the Maryland Section.

The 336th meeting of the Section was held on December 14, when Wm. Mansfield Clark spoke on "Oxidation-Reduction Indicators." The following officers for 1923 have been elected: William Mansfield Clark, president; J. B. Reed, secretary, H. W. Houghton, treasurer; W. W. Skinner, R. B. Sosman, R. C. Wells, W. D. Collins, and F. C. Cook, councilors; A. Seidel, L. H. Adams, E. T. Wherry, V. K. Chesnut, F. W. Smither, and R. O. E. Davis, executive committee.

J. B. Reed, secretary

#### WESTERN NEW YORK SECTION

On November 14, K. W. Stenstrom, of the New York State Institute for the Study of malignant Disease, addressed the Section, his subject being "Radium, its Value in Theory and Practice."

At the regular monthly meeting, held on December 5, J. C. McLennan, of the University of Toronto, gave a lecture on "The Structure of Atoms." R. W. Hess, Secretary

#### WISCONSIN SECTION

On November 15, Arnold Sommerfeld of the University of Wisconsin, addressed the Section. His subject was "Atomic Structure and the Periodic Law."

At the regular monthly meeting, held on December 13, E. C. Sherrard, of the University of Michigan, spoke on "Hydrolysis of Wood."

JESSE E. DAY, Secretary

#### DECEASED

Frederick North Crawford, 159 High St., Middletown, Conn. Died, November 4, 1922. Spencer Baird Newberry, 818 Engineers Building, Cleveland, O. Died, November 28, 1922. William E. Spandon, Columbia University, New York, N. Y. Died, November 17, 1922.

## Proceedings

### Report of the Secretary of the American Chemical Society for the Year 1922

The American Chemical Society is on the upgrade again in its active membership although the number at the end of this year differs little from that of 1921.

This is due to the fact that under the Constitution members are carried as members without journals or two years after they have ceased to pay dues, unless their resignation is received, in the expectation that they will remove their delinquency. Accordingly, at the end of 1922 a considerable number will be dropped from the membership count who really have not been of any assistance to the Society during the last two years. The industrial activity of the country is increasing and with it chemists who, during the depression, lost their positions are again finding profitable employment. In this returning prosperity the American Chemical Society itself is again beginning to share. During the depression the Society has not been idle. Strengous efforts have been put out to enlighten the country regarding the value of chemists and chemistry to the community. These efforts have met with a reasonable measure of success. Lectures by prominent members have been given before chambers of commerce, women's clubs, local sections of the Society, and have been transmitted by radio in order to enlighten the people as to the value of chemistry in everyday life. Six lectures by prominent members of the Society on special topics were given before the students and officers of the Naval Academy at Annapolis and of the Military Academy at West Point. The Society has received expressions of sincere appreciation for its efforts toward a better understanding of chemical problems by our military establishment from both academies. Similar lectures for the winter of 1922-1923 are now being arranged.

Our journals have increased in quality and usefulness. More research has been published than ever before. More pages have appeared in 1922 in the Journal of the American Chemical Society and Chemical Abstracts than have been printed in any previous year. The material in these pages, owing to the increased amount of material available has been scanned more severely so that quality has increased with quantity. The new editor of the Industrial and Engineering Chemistry has distinctly improved the appearance and the influence of that publication although its size has remained unchanged. Our advertising managers, even during the depression when other technical journals had been losing advertising, steadily and decidedly increased the number of our advertising pages. The net income from advertising in 1922 was much larger than ever before. As previously pointed out, this is simply a dividend returned to our members in the extra quality of the service the Society is able to render. The News Service is showing increased influence. Its releases are more widely used by the secular press. It has been also of special service to technical magazines. The News Service needs cooperation from our members in getting the right kind of material to send to the daily press and the manager of the News Service will gladly hear from our members regarding any available material. The News Service has already greatly diminished the amount of chemical quackery appearing in the public press so that most of the information regarding chemistry now printed can be depended upon. The correctness of the information furnished is the first thought of our News Service.

The Society has received special recognition from the War Department for, by the unsought request of that Department, a committee of the Society has been appointed to cooperate with the officers of the War Department in all matters requiring expert chemical advice.

The Society has entered into an agreement with the Chemical Society of London and the Faraday Society to publish under joint auspices the Journal of Physical Chemistry. Although the management of this journal will be quite independent, arrangement will be made where members of the three societies will obtain a reduced subscription price. The continuation of the Journal of Physical Chemistry under these new conditions is made possible by a guarantee of \$10,000.00 per year for five years from Mr. Francis P. Garvan in behalf of the Chemical Foundation and himself personally.

A medal, known as the Priestley Medal, has been established to be awarded annually for distinguished services to chemistry and will be awarded first at the New Haven Meeting of the Society April 3-7, 1923.

The Society has been made custodian, through the influence and recommendation of one of its Past Presidents, William H. Nichols, of a prize of \$25,000.00 to be awarded annually to some American chemist. The details of award are now under consideration.

Two successful meetings have been held during the year; one at Birmingham and one at Pittsburgh. They were well attended and added materially to the cause of chemistry both locally and throughout the country. The Sections of Cellulose Chemistry and Petroleum Chemistry have been given divisional status and have become enthusiastic and active divisions, progressive and well attended.

The American Chemical Society monographs are progressively successful. Nine monographs have been issued. Other important monographs will soon be issued and still others are in preparation. This new departure of the Society is already an assured financial success and the monographs are taking the stand in the chemical world which the Society would wish to see for any publication bearing its insignia.

In legislative matters the Society has been acting only under the strict control and direction of the Council or by the Committee on National Policy. The status of industrial alcohol has been distinctly improved, chiefly by enlarging the understanding of the absolute necessity for the use of alcohol in chemical manufacture as distinguished from its beverage use. The Lampert Bill for the improvement of the Patent Office and employees therein has been passed and signed by the President and the Society has received the courteous acknowledgment of the Commissioner of Patents for its successful efforts. The Society is active in supporting legislation in favor of Chemical Warfare Service and in attempting to impress those in authority with the absolutely essential support of research if the country is to be prepared to defend itself against the unscrupulous. The Society was successful in its efforts in assisting the protection of American manufacturers of chemicals and chemical apparatus. The effort put out by the chemists of the country, including the American Chemical Society, for proper legislation for the continuation of our organic chemical industry was not successful on account of skillfully prepared false propaganda and the selfish political activity of a minority consuming industry who preferred to put their own material interests before the country's chemical preparedness or its material welfare. Great progress was, however, made in educating the public, as well as the people's representatives, to a correct understanding of the value of chemistry, and the publications of the last Congress contained probably more material bearing upon true chemical science and chemical industry than all the publication of previous Congresses put together. A successful conference was held at the Pittsburgh Meeting on the Metric System, and the Society's representatives appeared in favor of the Ladd Bill to fix the Metric System of Weights and Measures as the standard for the United States. The Metric System is making distinct and rapid progress in the appreciation of our people. Its adoption, however, is, of course, expected to be slow, and the Society can only continue to be one of the helps towards its final acceptance.

The membership of the Society as reported last year was 14,318. The membership of the Society on December 31, 1922, was 14,400. Statistics follow:

Honorary Members	11
Life members	20
Corporation members	230
Members	14,150
	-
Total, December 31, 1922	14,400

The number of members not in arrears registered in the local sections on November 30, 1921, was 10,679. The number on November 30, 1922, was 9,947. The number in each section for 1921 and 1922 is noted below:

Local section	Number of paid mem- bers, 1921	Number of paid mem- bers, 1922	Cash retained from balance, 1921	Total receipts 1922
Alabama	44	38	\$ 67.50	\$ 67.50
Ames	48	40		70.50
Arkansas	30	23	.15	50.00
California	382	332		200.00
Central Texas	77	53		96.25
Chicago	801	716		600.75
Cincinnati	240	211		200.00
Cleveland	325	309	9.55	243.75
Colorado	91	71	34.98	84.98
Columbus	94	93		98.25
Connecticut Valley	112	103		135.00
Cornell	50	44	7.50	73.50
Delaware	175	141	40.08	175.00
Detroit	138	130		138.00
Eastern New York	101	86	3.27	126.25
Georgia	47	37	3.62	53.62
Hawaiian		24		50.00
Indiana	144	139		156.25
Iowa	77	88	2.56	96.25
Kansas City	182	169	67.49	182.00
Lehigh Valley	91	81	31.70	113.75

University of Michigan	66	70	17.35	77.35
University of Missouri	23	26	9.83	9.83
Vermont	27	25		50.00
Virginia	107	104		133.75
Washington, D. C	384	398	41.72	288.00
Western New York	248	210	72.99	186.00
Wisconsin	156	146	3.75	138.75
	10,679	9,947	\$886.68	\$9,429.04

The table gives a summary of the sectional accounts for the year, shows the number of members in each Section for 1921 and 1922, the funds held over from 1921 account, and the total funds (which include the balances) charged to the 1922 account.

During the year the Society added the Hawaiian, the Sacramento and the Northern West Virginia to its local sections, and discontinued the South Dakota Section.

During the past two fiscal years, December 1, 1920, to November 30, 1922, the Secretary has made the following collections:

	1921	1922
Membership	\$190,270.00	\$175,910.00
Subscriptions, non-members	21,154.26	21,292.48
Back numbers	6,295.62	6,139.44
Reprints	1,925.17	3,739.10
Postage	3,911.56	4,226.23
Interest	946.60	1,144.32
Exchange and miscellaneous	.56	.93
Directory	49.00	28.50
Decennial Index to Chemical Abstracts	610.00	565.00
	\$225 162 77	\$212.046.00

These amounts were duly transmitted to the Treasurer of the Society.

Full and explicit details of the business management of the Society for many years past will be found in the January 20 issue of the Industrial and Engineering Chemistry.

Several sets of Chemical Abstracts have been completed and sold during the year as well as complete sets of the Industrial and Engineering Chemistry. Complete sets of the Journal of the American Chemical Society can no longer be sold as it is impossible to fill in certain early numbers which are exhausted. Nevertheless, the Society has sold a number of incomplete sets to the extent that they could be completed, and there is still a demand for such, as full sets are almost unobtainable. The stock has been kept in good condition by the purchase of numbers needed to complete full volumes, but many volumes are already sold out and a number of issues of all three of our journals are nearing exhaustion.

Back numbers are mailed direct from Easton, Pa., on orders sent through the Secretary's office. The following is a summary of the back numbers sent out by the Secretary during the year, together with the present stock of journals:

Copies of the Society's publications sent out from January 1, 1922 to December	
31, 1922, aside from mailing lists	47,399
Copies of the Journal of the American Chemical Society in stock	21,893
Copies of Chemical Abstracts in stock	24,106
Copies of the Industrial and Engineering Chemistry in stock	22,187
Copies of the General Index, Vols. 1-20, J. A. C. S. in stock	70
Copies of the Anniversary Number in stock	87
Volumes of Decennial Index in stock	305

Respectfully submitted, Charles L. Parsons, Secretary

# Report of the Editor of the Journal of the American Chemical Society for the Year 1922

The number of articles and the number of the pages devoted to them and to the Proceedings of the Society during the past five years, exclusive of the indexes and the tables of contents, have been as follows:

		3	Numbe	r				Pages		
	1918	1919	1920	1921	1922	1918	1919	1920	1921	1922
Proceedings						112	162	168	128	117
Physical and Inorganic	114	107	180	179	191	1023	1053	1695	1688	1844
Organic and Biological	106	116	122	154	148	906	1089	936	946	1082
Book Reviews	21	29	54	57	47	30	31	59	70	48
								· ; <del></del> ;		
Total						2071	2335	2858	2832	3091

This table shows that in the past year for the first time, the maximum number of pages, 2944, reached in 1916, has been equaled.

The insistent demand for space in the Journal has continued. Moreover, a good deal of material accumulated during the printers' strike of 1921 and was carried over into 1922. Worst of all, the low state of the Society's finances forced the Directors to disapprove any increase in the size of the Journal over the preceding year. The outlook at the beginning of the year was, therefore, far from promising. Fortunately, however, a considerable decrease in the expense of printing was achieved, and as a result it was possible to publish the slightly increased number of pages indicated above. The average length of the articles in 1922 was 8.6 pages as compared with 8.2, 8.7, and 9.6 in 1921, 1920, and 1919.

At the end of the year, Associate Editors C. A. Browne and W. F. Hillebrand were retired by lot. The Editor wishes to express his own and the Society's appreciation

of their long, able and unselfish services. Roger Adams and E. W. Washburn were elected by the Council to the vacancies thus created.

ARTHUR B. LAMB, Editor

# Report of the Editor of Chemical Abstracts for 1922

The 1922 volume of Chemical Abstracts contains 23,212 abstracts, an increase of 3,736 over the 1921 volume. Of the abstracts 18,070 are of journal or like papers and 5,142 of patents. The number of titles of new or revised books in this volume is 886. The edition has averaged about 13,500 copies per number.

The average lengths of abstracts of papers and of patents in 1922, with comparative figures for the preceding five years, are shown in the following table, the unit being a page.

	1922	1921	1920	1919	1918	1917
Paper abstracts	0.190	0.218	0.223	0.244	0.220	0.251
Patent abstracts	0.086	0.098	0.107	0.115	0.099	0.108

The general average length for abstracts of papers for all of the preceding volumes is 0.225 page; that for patent abstracts for 13 preceding volumes (data are not available for volumes 1 and 2) is 0.98 page. The decrease in length of 1922 abstracts amounts to 15.5% for abstracts of papers and 12.2% for patent abstracts as compared with the general average of preceding volumes. This decrease, a very considerable one in view of the fact that brevity has always been emphasized, has been necessary in order that our efforts to cover the field completely might be carried out in the face of necessary space limitations. This necessity, a product of such circumstances as increased printing costs and the growth of the literature, is much to be regretted for there is no doubt that abstracts could be made more useful if it were possible to make them more informational. It may be pointed out, however, that every effort has been made to keep the briefer abstracts complete in the descriptive sense; this makes it possible for the indexing to be thorough. The indexing, particularly the subject indexing, has received continued special attention and no reduction has been made in the space devoted to the indexes, in the belief that the journal should be as nearly as possible a complete guide to the literature even though it cannot serve as the direct source of as much information as is desirable. It has still been possible to give suitable data and other information in most abstracts rather than merely references to them. The impression should not be gained that abstracts have had to be altered greatly; the point is that the tendency has had to be in the wrong direction. It will always be wise carefully to conserve space, but it will be a good thing for the journal when abstracts can be reasonably lengthened.

To provide just that much more space for chemical information the practice during 1922 has been to eliminate from abstracts the addresses of authors (laboratories where work reported was done). Addresses are helpful in appraising work and are useful in the obtaining of reprints. It is hoped, as has been requested by a number of chemists, that addresses can be reinstated eventually. The vote in response to a questionnaire on the subject was 72 to 20 in favor of devoting the space to chemical information so long as present conditions hold. In most cases initials only have been given in all but the surname part of author names. Abstractors' names are reduced to initials only by the printer when a line can thus be saved.

A point which has frequently been raised when the length of abstracts is under consideration is the relatively great length of the abstracts of organic papers. The reason these abstracts have a considerably higher average of length than the others lies in the

fact that, from the nature of things, a good deal more space is required for an adequate abstract of an organic paper than for an abstract on the same level of effectiveness and usefulness in any other field. The same is true of the indexing. Such a record as Chemical Abstracts constitutes would certainly not be complete and satisfactory if it did not at least briefly describe and index new compounds, and organic papers almost always contain descriptions of a number of such compounds. A markedly abbreviated style is used and the information given is limited. Another condition which affects the situation somewhat is the fact that organic papers are almost always all chemistry; there are no brief borderline abstracts to bring down the average. There is of course no desire to overemphasize any phase of chemistry. The 1922 organic abstracts are 18.5% shorter than those of 1921.

The field to be covered has grown considerably during the past few years owing to the fact that the physicists have been working more and more on subjects of distinct chemical interest, such subjects as atomic structure, radioactivity, gaseous ionization, crystal structure, spectroscopy and electron theory occupying their attention to a very large extent. There is so much direct chemical interest in these studies by physicists that it is necessary now to cover the physical journals almost as fully as the chemical ones. In this field and in the biological field (there are hundreds of biological and medical journals to be watched) it is particularly difficult to decide where to draw the line. The policy is to abstract in case of doubt, the abstracts of doubtful papers being made very brief as a rule.

Continued effort has been made to keep the nomenclature in Chemical Abstracts good. This is particularly true with reference to the systematic naming of compounds in the indexing.

In the October 20th number a revised "List of Periodicals Abstracted" was published. It gives information concerning 1010 publications. A new feature is the inclusion of location data for 172 libraries. This information was obtained through the coöperation of the National Research Council. There is much evidence that it is proving very useful. In helping users of Chemical Abstracts to obtain original papers it is serving to make up in part for the briefer abstracts which have been necessary.

It has been arranged to issue the 1922 indexes (author, subject and formula) in two parts, the first part consisting of the Author Index and the second containing the other two indexes. This seemed desirable because of binding difficulties resulting from the increased number of pages. The Author Index appeared near the middle of January and Part 2 is expected to go into the mails about February 20th. While quality of course comes before speed in the work on these indexes, which really present a rather big task in the printing as well as in the compilation and editing, every effort is made to get them into the hands of the users at the earliest possible time. The amount of work necessary in the compilation of the subject index in its present improved form and the addition of the Formula Index will not permit of the issuance of the complete index early in January, as was accomplished several years ago, but the 1922 indexes will be prompter than any since the Formula Index was added and it is expected that still better time can be made in another year if present plans can be carried out. The value of prompt indexes is recognized.

After many years of service as an abstractor and assistant editor Gerald L. Wendt has relinquished the reins as head of the section on Subatomic Phenomena and Radiochemistry to S. C. Lind, a good and faithful abstractor since the early days of the journal. Dr. Wendt deserves great credit for his work in developing this section. Paul E. Howe has taken over the work of Assistant Editor in charge of the section on Biological Chemistry, replacing William J. Gies, Hattie L. Heft and Edgar G. Miller, Jr.

Dr. Gies gave up the work after ten years of notably valuable service in which he was capably assisted by Miss Heft and Dr. Miller during the latter part of this period. B. M. Duggar has taken Carl L. Alsberg's place in charge of the sub-section on Botany. Dr. Alsberg's appreciated services also extended over a period of ten years. C. N. Frey is now in charge of the section on the Fermentation Industries, formerly handled by H. S. Paine, whose work for a number of years as an unusually capable abstractor from a variety of difficult languages well deserves our additional appreciation. Clarence J. West has assumed the place in charge of the Cellulose and Paper section made vacant by the resignation of A. D. Little, the beginning of whose valuable services for Chemical Abstracts dates back to the first appearance of the journal in 1907. The gratitude of all of us is due the retiring assistant editors and abstractors and the many now active in the work for their unselfish service. Their willingness to devote a lot of time to Chemical Abstracts with little or no pay furnishes a fine example of altruism. It would be difficult to overemphasize the value to the journal of this spirit of service. The editor wishes to express his appreciation to all again at this time.

Statistics for the various sections follow. Data are given for 1921 as well as 1922 since the delays caused by the printers' strike made it impossible to supply such figures in the report last year.

		1921	1	922
	No. of pages	No. of abstracts	No. of pages	No. of abstracts

# Report of the Editor of Industrial and Engineering Chemistry

The journal of Industrial and Engineering Chemistry has continued to place emphasis upon the publication of original papers, primarily upon research and chemical engineering, to which something more than 73 per cent. of its pages have been devoted. The discussion of industrial and plant problems has been made a feature and emphasis has been placed upon original research work. The September number, devoted to many reports of progress, was reprinted in phamphlet form and distributed to libraries of chambers of commerce. Two important symposia were published, one on distillation and the other upon automatic process control.

A number of new features have been introduced. Decided improvements have been made in the typographical features of the publication, synopses of the longer articles have been made a regular feature, letters have been secured from Canada and Japan, economic features have been stressed in special articles, lists of industrial films added, and the market reports expanded. A series on American contemporaries has been initiated and that part of the Journal devoted to government and new publications, book reviews, and scientific societies has been revised. The index for 1922 has been made more compact, and there has been constantly in mind the desirability of placing in the Journal more and more material of permanent interest and value.

Early in the year all the sections were invited to appoint staff correspondents and these correspondents have been of great assistance not only in supplying information, but in obtaining comments and criticisms. The Advisory Board has been active and has contributed much to any success which has been achieved. The editor has visited more than a third of the local sections and from these conferences has obtained much that will help him in conducting the Journal in accordance with the interests of readers. Further trips are in contemplation.

The editorial office performs a variety of service for industrial readers, advertisers, and local sections. The offer to act as a Washington Bureau in procuring special information has been widely accepted. The instructions of the Council in matters pertaining to legislation have been faithfully carried out and activities on numerous committees have all been in the interests of American chemistry.

The Advertising Department has been aggressive and is to be complimented upon the showing made. The Eschenbach Printing Company has given cooperation which left nothing to be desired, and through efficient management has enabled very substantial savings to be made in the cost of printing.

Analysis discloses that 1 per cent. of the space of the Industrial and Engineering Chemistry has been devoted to tables of contents; 1.7 to the index; 2.83 to

editorials; 21.33 to notes and correspondence, scientific societies, foreign letters, Washington notes, government and new publications, book reviews, market reports and other miscellaneous material; and 73.78 to original papers and other contributed articles or research and industrial chemistry.

The following comparison with 1921 may be made:

Number of Separate Articles		
•	1921	1922
Editorials	53	. 97
Original Papers	310	316
Foreign letters, Market reports, Notes, Scientific		
societies, etc	105	141
Book Reviews	67	81
	-	<del></del>
	535	635

The office equipment has been repaired and put in first class condition, worn typewriters replaced, and surplus property sold. The reference journal volumes have been bound and the net assets of the Society increased in these several ways.

Preliminary figures indicate these totals:

	1921	1922
Gross cost, all items except advertising	\$81,256.20	\$69,072.25
Cost of printing advertising	38,105.37	28,229.42
Net return from advertising	39,034.09	50,000.00

Gratitude is expressed to authors whose coöperation has made it possible to maintain the high standard of the Industrial and Engineering Chemistry, to advertisers without whose valued support not only this publication but all the publications of the Society would suffer, and to the many reviewers who have generously given their time for the consideration of manuscripts and new books.

Authors are asked to write as compactly as possible and to omit nonessential material, remembering that shorter articles are read with greater interest by a larger number, thus advancing the interests of both author and reader. The approximate percentage of total circulation represented by each of the several special interests served by the Journal has been determined, and in so far as is possible articles for each number will be selected with a view to serving these several special groups.

# NEWS SERVICE

The News Service has been conducted with several definite objects in view. These may be designated as the promotion of research, the exposure of fakes, the development of special interests represented by divisions of the Society, publicity for the semiannual meetings, assistance to local sections, and the furtherance of legislative matters in accordance with the instructions of the Council.

A special effort has been made to have the nontechnical press seek the advice of specialists through the News Service before printing sensational announcements, and where this could not be forestalled, correct explanations and data have been given through releases. Not only through newspapers but through trade publications, an effort has been made to interest definite groups of manufacturers in what research may be expected to do for them. An illustration of this is the use by 67 newspapers of an article a column in length on the opportunities in the leather industry for the application of chemistry.

The instructions of the Council relative to service at the general meetings have been faithfully executed. Abstracts in so far as they could be procured preceding the two general meetings were prepared and supplied to the technical and daily press. This service is being steadily improved and, beginning with the New Haven meeting, it is proposed to extend it to certain division members as provided by their division by-laws. While many local sections have acted through successful publicity committees, others have requested and been given assistance by the News Service with the result that greater attention is paid locally to the activities of chemists.

An increase in publicity has been obtained with a decrease in expenditure.

	Expenses	Inches of publicity measured
1917	\$ 500	no record*
1918	1,850	5,000
1919	2,069	9,000
1920	8,078.69	21,000
1921	12,792.93	70,000
1922	10,306.12	79,101

* It will be remembered that in 1917, 1918 and 1919 the News Service was operated as a Society committee activity.

There have been 88 separate releases, not counting items printed in the Chemical Round Table, so that the total items circulated are in excess of 100. The clippings received in the office number 8,107 and measure 79,101 inches. Much of the material is rewritten by the press before use, and if the American Chemical Society is not mentioned, clippings are not received. Further, no clipping bureau obtains all the clippings. It is fair to estimate that the 79,101 inches represent only a part of the total publicity obtained.

A more accurate system for checking results has been developed so that the date upon which the release was issued, the author of the story, its subject, the number of clippings received, and their total measurement can be reported. Exhibits are on file and are always open for the examination of those interested.

The publicity work of the Society is just beginning to bear fruit. The results of the last half of 1922 clearly show an inclination on the part of the press to give more and more space to scientific news, notwithstanding the increased demand upon space. Frequently interesting releases which are not closely connected with definite dates are used long after the official mailing and we are still receiving clippings of articles released in January 1922.

The News Service has assisted in creating a favorable attitude on the part of the public toward research. Still greater results can be obtained if increased coöperation can be secured from the research and industrial chemists. Many news items remain unused because men engaged in the work do not recognize their news value. There is a greater demand for authentic scientific news in newspaper language than can be met with the material ordinarily received and the News Service not only heartily thanks those who have been of great assistance during the work of the present year, but bespeaks still further efforts in 1923.

H. E. Howe, Editor

# COUNCIL

MEMBERS ELECTED BETWEEN DECEMBER 15, 1922 AND JANUARY 15, 1923

Abe, Ryonosuke, Laboratory of Engineering Chemistry, Imperial University, Kyoto, Japan. Ackley, Adrian L., Phi Eta Kappa, Orono, Maine.

Affleck, John K., 2 Spading Road, Toronto, Ont., Canada.

Alwood, Fred W., 609 E. Johnson St., Clinton, Ill.

Amidon, Geo. W., American Institute of Baking, 1135 Fullerton Ave., Chicago, Ill.

Anthony, John K., 316 Highland Road, Ithaca, N. Y. Armstrong, Merton S., 85 Linwood Ave., Buffalo, N. Y. Armstrong, Thos. B., 122 Chicago Ave., Hinsdale, Ill. # CORPORATION MEMBERS ELECTED

The International Nickel Co., 67 Wall St., New York City. Thompson's Malted Food Company, Waukesha, Wis.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

### CALIFORNIA SECTION

The 136th regular meeting of the Section occurred on December 29, 1922, when Oliver C. Ralston, superintendent of the Pacific Experiment Station of the U. S. Bureau of Mines, addressed the members, his subject being "Aluminum Chloride, its Manufacture and Uses."

At the above meeting, the following officers for 1923 were elected: Carl L. Alsberg, chairman; C. W. Porter, vice chairman; L. H. Duschak, secretary-treasurer; W. C. Bray, R. A. Gould, J. H. Hildebrand and Arthur Lachman, councilors.

L. H. Duschak, Secretary

# CENTRAL TEXAS SECTION

At the annual fall meeting of the Section, held at College Station, Texas, the following officers for 1923 were elected: N. C. Hammer, chairman; W. Arthur, vice chairman; W. W. Battle, secretary-treasurer; J. R. Bailey, councilor. W. W. Battle, Secretary

### CHICAGO SECTION

On January 19, the program of the meeting was under the auspices of the women members of the Section, Miss Elizabeth Weirick presiding. The address of the evening was by Mrs. Elizabeth Miller Koch on "Sunlight as a Factor in the Vitamin Problem." Group meetings with discussions of subjects under (1) laboratory methods (inorganic), (2) laboratory methods (inorganic), (3) synthetic, and (4) biologic, were conducted.

S. L. Redman, Secretary

# CINCINNATI SECTION

The 255th regular meeting of the Section was held on January 17, and was addressed by Carey Pratt McCord, and Robert A. Kehoe, both of the University of Cincinnati, their subjects being "Some Aspects of Industrial Poisoning," and "The Nature of Heavy Metal Poisoning and its Relief," respectively.

The following officers for the Section have been elected for 1923: Martin H. Fischer, president; A. S. Richardson, vice president; H. M. Williams, second vice president; A. O. Snoddy, secretary-treasurer; Archibald Campbell, trustee; C. P. Long, A. B. Davis and H. J. Morrison, councilors.

A. O. Snoddy, Secretary

### CLEVELAND SECTION

At the regular meeting of the Section, held on December 27, George Oenslager, of the B. F. Goodrich Rubber Co., addressed the members on "The Rubber Plantation Industry in the Far East and the Preparation of Rubber for the World's Market." At this meeting the following officers for 1923 were elected: W. R. Veazey, chairman; L. C. Drefahl, vice chairman; H. S. Booth, secretary-treasurer; L. C. Drefahl, A. W. Smith, O. F. Tower and W. R. Veazey, councilors.

The members of the Section were invited to attend the meeting of the Associated Technical Societies of Cleveland on the night of January 9, the topic of the evening's addresses being "The Steel Industry as Affected by the Life of the late Samuel T. Wellman."

H. S. BOOTH, Secretary

# CONNECTICUT VALLEY SECTION

On January 13, the members of the Section enjoyed a trip through the Strathmore Paper Company's plant at Springfield, Mass. In the evening of that day, an address was given by William P. Ryan, of the Massachusetts Institute of Technology on "Some Aspects of the Sizing of Paper."

PAUL SERREX, JR., Secretary

# CORNELL SECTION

At a meeting of the executive council of the Section, held on December 14, A. W. Browne was elected to serve as councilor.

F. E. Hance, Secretary

### DELAWARE SECTION

At the December 20th meeting, the following officers for 1923 were elected: F. C. Zeisberg, chairman; J. F. Garrett, vice chairman; J. L. Bennett, treasurer; J. W. Stillman, secretary; C. L. Reese and C. M. Stine, councilors.

J. W. STILLMAN, Secretary

#### DETROIT SECTION

The regular meeting of the Section was held on January 17, when William K. Sawyer, of Morgan & Wright Company, Detroit, Mich., spoke on the subject, "Cotton Fabrics."

S. R. Wilson, Secretary

### EASTERN NEW YORK SECTION

The following officers for 1923 have been elected: G. R. Fonda, chairman; Arthur Knudson, vice chairman; Edward Darby, secretary-treasurer; Saul Dushman and Edward Ellery, councilors; G. M. J. Mackay, Mrs. M. R. Andrews and W. P. Davey, executive committee.

E. H. DARBY, Secretary

### INDIANA SECTION

On December 8, the members of the Indiana Section were the guests of the Van Camp Packing Co., at Indianapolis. A complimentary dinner was served to the 135 guests present. The trip of inspection was preceded by a talk by Mr. Rutledge of the Van Camp Company who welcomed the guests and explained some of the plant operations. Two talks followed the trip, one by C. E. Stone on "Progress of Science in Food Preservation, and one by W. L. Clark, on "The Manufacture and Analysis of Evaporated Milk."

E. R. Weidlin, director of the Mellon Institute of Industrial Research, addressed the Section, on January 12, his subject being "The Value of Industrial Research."

WILLIAM HIGBURG, Secretary

### IOWA SECTION

The regular monthly meeting of the Section was held at Iowa City on December 13, with the following program: "The Promoter Action of Certain Compounds on the Activity of Urease," by W. J. Husa; "The Weight of the Acyl Radical as a Factor in the Molecular Rearrangement of Diacylated Ortho-Aminophenols," by J. R. Couture; and "The Effect of Acidity of the Radical in the Molecular Rearrangement of Diacylated Ortho-Aminophenols."

On January 12, Victor Lenher, of the University of Wisconsin, lectured before the Section, his subject being "Selenium Oxychloride."

The following officers for 1923 have been elected: L. Chas. Raiford, chairman; H. F. Lewis, vice chairman; G. H. Coleman, secretary; Edward Bartow, councilor.

G. H. COLEMAN, Secretary

# KANSAS CITY SECTION

On December 16, H. P. Cady gave an address before the members, his subject being "The Composition of the Atom." At this meeting the following officers for 1923 were elected: R. Q. Brewster, chairman; C. F. Gustafson, vice chairman; Lee E. Clark, secretary-treasurer; Robert Taft, assistant secretary; F. B. Dains and Rudolph Hirsch, councilors.

At the meeting of the Section, held on January 17, Wm. J. Reese spoke on "The Interpretation of the Analysis of Soap Materials."

Lee E. Clark, Secretary

### LEHIGH VALLEY SECTION

The following officers have been elected by the Section for 1923: E. C. Bingham, chairman; L. F. Witmer, vice chairman; R. H. Bogue, secretary-treasurer; J. P. Little, councilor.

R. H. Bogue, Secretary

### LOUISVILLE SECTION

At the November meeting of the Section, the following officers for 1923 were elected: C. E. Bales, chairman; T. J. Bosman, vice chairman; C. E. Geiger, secretary-treasurer; A. W. Homberger, councilor; T. J. Bosman, R. Camp and C. E. Geiger, membership committee; C. E. Bales, A. W. Homberger and G. A. Goodell, program committee.

C. E. GEIGER, Secretary

### MAINE SECTION

At the regular meeting of the Section, held on January 12, C. A. Brautlecht, of the University of Maine, addressed the members on the subject, "Chemistry of Fuel, Heat and Light (Illustrated)."

The following officers have been elected by the Section for 1923: C. A. Brautlecht, president; J. M. Bartlett, vice president; N. E. Woldman, secretary-treasurer; A. B. Larchar, councilor.

N. E. Woldman, Secretary

# MARYLAND SECTION

The 61st meeting of the Section was held on December 29, with the following program: "Trivalent Titanium in Analysis," by W. M. Thornton; "Soil Colloids and the Theory of Adsorption," by Neil Gordon; and "A Laboratory-made Vacuum Oven," by W. B. D. Penniman.

ADOLPH HARVITT, Secretary

### MIDLAND SECTION

The 14th meeting of the Section was held on November 21, when M. E. Putman discussed the New York Chemical Exposition, and Ralph Hunter spoke on "Electrolytic Caustic Cells."

The 15th meeting occurred on December 19. Roy Osmun presented a paper on the "Transformations, Uses, Losses, and Costs of the Heat Energy of Coal in the Dow Chemical Plants."

John A. Gann, Secretary

# MILWAUKEE SECTION

On January 12, C. A. Nash addressed the members of the Section on the subject, "The Chemist in the Molding Industry."

A. A. CHAMBERS, Secretary

# NEW HAVEN SECTION

At the regular meeting of the Section, held on January 16, R. E. Swain, of Leland Stanford University, spoke on "Some Aspects of the Smoke Problem."

BLAIR SAXTON, Secretary

# NEW YORK SECTION

A joint meeting of the local Section and the Societe de Chimie Industrielle was held on January 5. A special program was arranged commemorating the centenary of the birth of Louis Pasteur, as follows: "Pasteur and the Science of Fermentation," by Gary N. Calkins, of Columbia University; "Pasteur and Chemical Asymmetry," by John M. Nelson, of Columbia University. John W. Churchman, of Cornell University, spoke on "The Selective Bacteriostatic Properties of Certain Dyes."

The following officers for 1923 have been elected by the Section: C. A. Browne, chairman; C. E. Davis, vice chairman; B. T. Brooks, secretary-treasurer; Martin H. Ittner, James Kendall, H. C. Parmelee, and Herbert G. Sidebottom, executive com-

mittee; C. A. Browne, C. E. Davis, B. T. Brooks, James Kendall, H. C. Parmelee, H. G. Sidebottom, R. G. Wright, T. H. Getmann, Ellwood Hendrick, K. G. MacKenzie, David Wesson, H. R. Moody, Martin H. Ittner, A. C. Langmuir, D. W. Jayne, B. R. Tunison, A. W. Thomas, W. Haynes, and Lois M. Woodford, councilors.

B. T. BROOKS, Secretary

### NORTHEASTERN SECTION

The 181st meeting of the Section occurred on January 12. George B. Magrath, medical examiner of the Suffolk District, spoke on "Medical Examiner Service." Motion pictures showing the operations of the American Sugar Refining Company were shown and explained by W. van V. Warren.

E. B. Millard, Secretary

### PHILADELPHIA SECTION

On January 18, Julius Stieglitz, of the University of Chicago, addressed the members of the Section, his subject being "Some Problems in the Field of Chemistry and Medicine."

J. HOWARD GRAHAM, Secretary

# PITTSBURGH SECTION

The 184th meeting of the Section was held on January 18, with the following program: "Manufacture and Use of Enamel-Lined Apparatus," by Emerson P. Poste; "Manufacture and Properties of Oven Glass Cooking Ware," by Ralph F. Brenner; and "Manufacture of Electrical Porcelain," by E. H. Fritz.

The following officers have been elected by the Section for 1923: E. R. Weidlein, chairman; A. Silvermann, vice chairman; E. S. Stateler, secretary; C. E. Nesbitt, treasurer; A. C. Fieldner, J. O. Handy, E. W. Tillotson, R. E. Zimmerman, and H. C. P. Weber, councilors.

### PUGET SOUND SECTION

The Section has elected the following officers for 1923: Thomas G. Thompson, chairman; A. G. Bissell, vice chairman; R. W. Ellison, secretary; G. C. Howard, treasurer; H. K. Benson, councilor.

R. W. Ellison, Secretary

# PURDUE SECTION

The regular monthly meeting of the Section was held on December 14, when R. H. Carr, of Purdue University, gave a lecture on "Soil Toxicity," and F. O. Anderegg, of Purdue University, on "Water, The Most Peculiar Liquid."

MARGUERITE G. MALLON, Secretary

# ROCHESTER SECTION

The 147th regular meeting of the Section was held on January 8, when C. E. K. Mees spoke on "Motion Picture Photography for the Amateur."

On January 19 and 20, the Section presented a symposium on Physical Chemistry, with seventeen speakers giving lectures on that subject. Erle M. Billings, Secretary

# SACRAMENTO SECTION

At the meeting of the Section, held on January 13, G. H. P. Lichthardt, of the California State Department of Public Works, spoke on "Colloidal Chemistry and Its Application."

J. H. Norton, Secretary

### SAINT LOUIS SECTION

On January 8, the Section had the following program: "Beyond the Microscope," by Gerald L. Wendt.

H. A. Carlton, Secretary

### SOUTHEAST TEXAS SECTION

The following officers have been elected by the Section for 1923: L. S. Bushnell, president; W. A. Slater, vice president; L. B. Howell, treasurer; P. S. Tilson, secretary; F. M. Seibert, councilor.

P. S. Tilson, Secretary

# SOUTH JERSEY SECTION

The 17th regular meeting of the Section occurred on December 12, the following papers being presented: "Vitamins from a Historical and Chemical Standpoint," by W. S. Calcott; and "Vitamins from a Medical Standpoint," by R. S. Sutherland.

On January 24, W. A. Peters, Jr., addressed the members of the Section, his subject being "Recent Developments in the Theory and Practice of Distillation."

The following officers for 1923 have been elected: H. W. Mahr, chairman; A. F. Odell, vice chairman; W. Fletcher Twombly, secretary-treasurer; W. S. Calcott, councilor.

W. FLETCHER TWOMBLY, Secretary

### SYRACUSE SECTION

On January 3, R. Adams Dutcher, of Pennsylvania State College, addressed a special meeting of the Section, his subject being "Vitamins."

At the regular meeting of the Section, held on January 12, G. I. Vincent addressed the members on the subject, "The Manufacture of Gas."

M. T. Bogert, of Columbia University, gave a lecture before the members of the Section on January 26. His subject was "Perfumes, Natural and Synthetic."

W. B. HICKS, Secretary

#### TOLEDO SECTION

At the regular meeting of the Section, held on December 19, Carrol S. Lyman spoke on "The Manufacture of Asphalt Blocks."

On January 8, Robert E. Wilson, of the Standard Oil Company, addressed the Section, his subject being "The Mechanism of the Corrosion of Iron."

GUY E. VAN SICKLE, Secretary

# UNIVERSITY OF ILLINOIS SECTION

The regular meeting of the Section was held on December 20. F. W. Mohlman, chief chemist for the Sanitary District of Chicago, spoke on "Chicago's Sewage Disposal problems."

The 126th regular meeting of the Section occurred on January 12, when F. C. Whitmore, of Northwestern University, addressed the members on the subject "The Human Side of Mercury."

D. T. Englis, Secretary

# UNIVERSITY OF MICHIGAN SECTION

The annual business meeting of the Section was held on December 14, when the following officers for 1923 were elected: C. S. Schoepfle, chairman; H. H. Willard, councilor; C. C. Meloche, secretary; W. L. Badger, A. L. Ferguson and R. K. McAlpine, executive committee.

On January 16, A. H. White spoke before the Section on the subject, "Waterproof Concrete."

C. C. Meloche, Secretary

# UNIVERSITY OF MISSOURI SECTION

On December 7, W. N. Stull, of the Mallinckrodt Chemical Works, St. Louis, Mo., spoke before the meeting of the Section, his subject being "Qualifications Necessary in an Industrial Chemist."

The following officers for 1923 have been elected: H. Schlundt, chairman; I. Stanley, vice chairman; H. D. Hooker, Jr., councilor; H. E. French, secretary; and M. V. Dover, treasurer.

H. E. French, Secretary

# Proceedings

# ADVISORY COMMITTEE

On February 3, 1923, the following communication was sent to the Committee on National Policy, and was unanimously approved:

Washington, D. C., February 3, 1923

Committee on National Policy, American Chemical Society: Gentlemen:

The enclosed documents which the Chairman of our Committee on Industrial Alcohol wishes me to send you for your approval are self-explanatory. The Secretary has no additional information except to state that, so far as he is aware, it is the unanimous opinion of all those who have looked into the matter that the proper administration of Title 3 and the appointment of a special industrial alcohol commissioner will unquestionably add both to prohibition enforcement and to the proper use of alcohol for industrial purposes. The chairman of the committee writes me that they have taken the matter up informally with some of the leading officers of the Government and that they have good reasons to believe that these arguments will be welcome and appropriate.

Will you kindly send in your approval or disapproval at the earliest possible moment.

Sincerely yours,

CHARLES L. PARSONS
Secretary

The American Chemical Society recognizing the necessity for proper legal provision for a supply of alcohol, and for the use of alcohol as a chemical raw material and for other lawful purposes, on the advice of its Committee on Industrial Alcohol regularly established for the purpose of consulting and advising on matters pertaining to industrial alcohol, as a whole through its Committee on National Policy hereby presents the following recommendation:

"In order that the National Prohibition Act may be more equitably and effectively administered and that industries depending upon the use of industrial alcohol may be permitted to operate under reasonable regulations and be encouraged as expressly provided in the law, and in order that violations of the law may be more readily prosecuted, the American Chemical Society recommends that Title 3 of that act pertaining to industrial alcohol shall be given equal weight in enforcement with other portions of the act, and recommends that, to this end an Industrial Alcohol Commissioner be appointed with authority equal to an apart from the Prohibition Commissioner, whose duties shall be the administration of those portions of the law pertaining to industrial alcohol."

The enforcement of the National Prohibition Act has been, up to the present, largely in the hands of the Prohibition Commissioner. This officer has naturally been selected principally because of his fitness to enforce the prohibition features of the law. It is perhaps too much to expect that the Prohibition Commissioner shall be a technical man and that he shall in addition to his policing duties in the interest of prohibition also jealously guard the interests of alcohol-using industries, yet this is precisely what the law contemplated as evidenced by section 13 Title 3 of the National Prohibition Act which is as follows:

"The Commissioner shall from time to time issue regulations respecting the establishment, bonding, and operation of industrial alcohol plants, denaturing plants, and bonded warehouses authorized herein, and the distribution, sale, export, and use of alcohol which may be necessary, advisable, or proper, to secure the revenue, to prevent diversion of the alcohol to illegal uses, and to place the non-beverage alcohol industry and other industries using such alcohol as a chemical raw material or for other lawful purpose upon the highest possible plane of scientific and commercial efficiency consistent with the interests of the Government, and which shall insure an ample supply of such alcohol and promote its use in scientific research and the development of fuels, dyes, and other lawful products."

The Commissioner is specifically charged in this section with broad and important duties of administration. We recommend that the Commissioner, acting on the authority here conferred, apportion the administration of the law among the coördinated officers, both holding office as Assistant Commissioners of Internal Revenue; the Industrial Alcohol Commissioner, and the Prohibition Commissioner.

With an Industrial Alcohol Commissioner, preferably a technical man himself, and with technical men on his staff, the needs of the industries would necessarily be better looked after and it would be easier thus to prevent diversions of alcohol to unlawful purposes, such as have occurred in the past where the granting of permits has been left to men unfamiliar with the industries but selected mainly because of their fitness to enforce the prohibition end of the law.

With two coordinated officers looking after industrial alcohol and prohibition enforcement, the possibility of unlawful procurement of alcohol through corruption would be greatly lessened.

MARTIN H. ITTNER.

Chairman, Committee on Industrial Alcohol, American Chemical Society

# **AUDITORS' REPORT**

New York, Tanuary 18, 1923

Dr. J. E. Teeple, Chairman Finance Committee:

American Chemical Society

50 East 41st Street, New York City

### Dear Sir:

Pursuant to your request, we have made an audit of the books of account of the American Chemical Society, kept by its Treasurer, for the year ending December 31, 1922, and submit herewith the accompanying Condensed General Balance Sheet as of December 31, 1922, and Statement of Cash Received and Disbursed Between January 1, and December 31, 1922—marked Exhibit "A" and Exhibit "B," respectively, which we have prepared thereform; and hereby

CERTIFY that such statements correctly reflect the financial condition of the Society at December 31, 1922 and its financial transactions during the year, as shown by the books of account.

# Yours very truly,

(Signed) McCulloh and Brown
Certified Public Accountants

Underwood, Wm. Frederick, 106 13th Ave., Columbus, Ohio.

Vardy, Wm. Andrew Shakespeare, Fox Holes Bungalow, Methley, near Leeds, England.

Vivian, Hugh, Messrs Vivian & Sons, Ltd., Swansea, Glam, England.

Vogt, Richard R., 721 Cottage Grove Ave., South Bend, Indiana,

Walker, Lester H., Elm St., Potsdam, N. Y.

Waterman, Ivan R., 2312 College Ave., Berkeley, Cal.

Welch, Isabelle M., 9 W. Melrose St., Chevy Chase, Md.

Wenger, R. G., 48 Ninth East St., Salt Lake City, Utah.

Wilharm, William C., 129 Gordon St., Edgewood, Pittsburgh, Pa.

Williams, George A., Atlantic Christian College, Wilson, N. Car.

Winslow, Arthur F., 307 H. H. Hall, University of Maine, Orono, Maine.

Wood, Henrietta Cooper, 16 Mountwell Ave., Haddonfield, N. J. Wood, James, Cooperative Wholesale Society, Research Dept., 109 Corporation St., Manchester, England.

Woolley, S. W., 42 Cannon St., London, England.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

### AMES SECTION

On January 11, Victor Lenher, of the University of Wisconsin, spoke on "Selenium and Its Compounds."

On January 17, L. J. Matos, of the National Aniline & Chemical Company, addressed the meeting, his subject being "Dyes and Dyeing."

On January 27, Gerald N. Wendt, research chemist of the Standard Oil Company of Indiana, gave a lecture before the meeting of the Section. His subject was "Rewards of Scientific Research."

At the meeting of the Section, held on January 31, H. E. Howe spoke on "Fundamental Research as a National Factor."

H. M. McLaughlin, Secretary

# CALIFORNIA SECTION

The members of the Section gave a dinner, on February 2, at the Hotel Bellevue, San Francisco, Cal., in honor of E. C. Franklin, of Stanford University, the newly elected president of the American Chemical Society.

L. H. Duschar, Secretary

### CINCINNATI SECTION

The 256th regular meeting of the Section occurred on February 14, when A. P. Mathews, professor of physiological chemistry at the University of Cincinnati, addressed the members on "The Origin of the Organic Substances on the Earth's Surface."

A. O. SNODDY, Secretary

### CLEVELAND SECTION

The regular monthly meeting of the Section, held on January 26, was addressed by C. J. Ramsburg, of the Koppers Company, Pittsburgh, Pa., his subject being "Coke."

On February 21, William J. Hale, of the Dow Chemical Co., Midland, Mich., addressed the Section on the subject of "Our Chemical Awakening."

H. S. BOOTH, Secretary

### COLORADO SECTION

On January 24, W. W. Scott, of the Golden School of Mines, addressed the Section his subject being "Researches in the Catalytic Oxidation of Ammonia."

RUTH B. VERTREES, Secretary

### CONNECTICUT VALLEY SECTION

At the regular monthly meeting of the Section, held on February 10, Amos Bissell, of the Bissell Varnish Company, Bridgeport, Conn., gave an address on "Uses of Varnishes and Baking Japans."

PAUL SEREX, JR., Secretary

### DELAWARE SECTION

On February 21, Brig. Gen. Amos A. Fries, chief of the Chemical Warfare Service, War Department, Washington, D. C., addressed the meeting of the Section, his subject being "Chemical Warfare Materials—What They Are, How Produced, and Peacetime Uses."

J. W. STILMAN, Secretary

# DETROIT SECTION

A joint meeting of the Associated Technical Societies of Detroit, of which the Local Section of the American Chemical Society is a member, was held on January 19. The speaker was Harvey Wiley Corbett, who lectured on "Some Phases of Architectural Development as Affected by Zoning Laws."

The following program was presented before the meeting of the Section on February 21: "General Curricula and Policy of the Cass Technical High School," by E. G. Allen, assistant principal; "The Curricula of the Science Group," by J. C. Moore, head of science group; "The Relation of the School to Industry," by S. R. Wilson, vocational counselor; and an inspection of the Cass Technical High School.

S. R. WILSON, Secretary

### GEORGIA SECTION

On February 15, H. E. Howe, editor of Industrial and Engineering Chemistry, addressed the Section, his subject being "The Policy and Plans of the Society Publications."

L. B. LOCKHART, Secretary

### HAWAHAN SECTION

At a meeting of the Section, held on February 1, D. D. Van Slyke, of the Rockefeller Institute, spoke before the members, taking as his subject "Important Research Investigations Undertaken by the Rockefeller Institute." RONALD Q. SMITH, Secretary

# INDIANA SECTION

On January 9, H. E. Barnard, of the American Institute of Baking, addressed the Section on "The Opportunities for Chemical Research in the Baking Industry." H. E. Howe, editor of Industrial and Engineering Chemistry, was the speaker at the January 23 meeting, when he discussed the various phases of the publications of the Society. I. I. Birdsall, of the General Chemical Company, spoke to the Section at its January 30 meeting on the subject of "Edible Fungi."

At the regular monthly meeting of the Section held on February 9, Albert P. Mathews, of the University of Cincinnati, spoke before the members, his subject being "New Light on the Origin of the Organic Substances on the Earth's Surface."

WILLIAM HIGBURG, Secretary

### IOWA SECTION

The members of the Section were addressed by H. E. Howe, editor of Industrial and Engineering Chemistry, on February 1, his subject being "Publication Problems and Society Procedure."

G. H. COLEMAN, Secretary

### LEXINGTON SECTION

The following officers of the Section have been elected for 1923: J. A. Gunton, president; L. A. Brown, vice president; J. R. Mitchell, second vice president; H. P. Newton, councilor, and E. L. Jackson, secretary-treasurer.

The 85th meeting of the Section was held on February 20, when A. P. Mathews, of the University of Cincinnati, spoke on "The Origin of Organic Substances on the Earth's Surface."

B. I. Jackson, Secretary

# LOUISIANA SECTION

On January 19, H. Z. E. Perkins, of the American Sugar Refining Co., presented a paper entitled "Hydrogen Ion Determination as a Method of Refinery Control." At this meeting the following officers for 1923 were elected: Cassius L. Clay, chairman; S. A. Mahood, vice chairman; C. E. Coates, councilor; H. R. Stevens, secretary-treasurer.

H. R. STEVENS, Secretary

# MAINE SECTION

At the regular meeting of the Section, held on February 12, W. H. Jordan spoke on "Chemistry in the Experiment Stations."

N. E. WOLDMAN, Secretary

# MARYLAND SECTION

The 62nd regular meeting of the Section occurred on January 26. T. B. Hine, of Edgewood Arsenal, presented a paper on "A Few Scientific By-Products of Recent Chemical Warfare Research."

The 63rd meeting of the Section was held on February 23. A lecture, entitled "The Physical and Chemical Properties of Atomic Hydrogen," was delivered by R. W. Wood, of Johns Hopkins University.

About Harvitt, Secretary

### MILWAUKEE SECTION

On February 16, Gerald L. Wendt, of the Standard Oil Company, spoke before the members of the Section, his subject being "Beyond the Microscope."

ALFRED A. CHAMBERS, Secretary

### MINNESOTA SECTION

The 106th regular meeting of the Section was held on January 16, when Edward Bartow, of the University of Iowa, gave an address on "The Activated Sludge Process of Sewage Disposal and its Present Status." The address was illustrated with lantern slides.

The Local Section met with the Northwest Chapter of the American Society for Steel Treating in a joint session, on February 19. The address of the evening was by Paul D. Merica, director of research of the International Nickel Company, his subject being "Nickel, Its Metallurgy and Industrial Applications."

L. M. HENDERSON, Secretary

# NASHVILLE SECTION

The 83rd regular meeting of the Section occurred on January 19, when William Litterer, state bacteriologist and professor of bacteriology, medical department, Vanderbilt University, spoke on "Some Virulent Diphtheria Bacilli in Fowls."

On February 8, H. E. Howe, editor of Industrial and Engineering Chemistry, spoke before the members of the Section, his subject being "Publication Problems and Society Procedure."

H. A. Webb, Secretary

#### NEW HAVEN SECTION

At the regular meeting of the Section, held on February 13, Ellwood Hendrick spoke on "Obligations in Chemistry." The following officers for 1923 were elected: T. B. Johnson, chairman; John F. Hutchinson, vice chairman; H. W. Foote, councilor; John L. Christie, treasurer, and Blair Saxton, secretary.

BLAIR SAXTON, Secretary

# NEW YORK SECTION

A joint meeting of the four chemical organizations in New York City was held on February 9, with the following program: "The Present Situation in the Radium Industry," by Harold E. Bishop, of the Radium Company of Colorado; and "Observations of Industrial Conditions in Europe," by W. S. Landis, of the American Cyanamid Company.

Benjamin T. Brooks, Secretary

# NORTHEASTERN SECTION

The 182nd regular meeting of the Section occurred on February 9, when Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers Association, spoke on "The Present Status of the American Synthetic Organic Chemical Industry."

E. B. MILLARD, Secretary

# NORTHERN INDIANA SECTION

On January 17, F. C. Mathers, of Indiana University, spoke to the Section, his subject being "The Electroplating and Refining of Metals." The following officers for 1923 have been elected by the Section: E. N. Weber, chairman; P. J. Byrne, Jr., vice chairman; J. A. Nieuwland, councilor; M. W. Lyon, Jr., treasurer; and V. C. Bidlack, secretary.

V. C. Bidlack, Secretary

# NORTH CAROLINA SECTION

At a meeting of the Section held on February 14, H. E. Howe, editor of Industrial and Engineering Chemistry, spoke on "The Trend of Scientific Research and its Bearing on Future Civilization." In the afternoon of the same day, Mr. Howe addressed a special meeting of the Section on "Policy, Procedure, Finance and Plans of the Society."

L. B. RHODES, Secretary

### OMAHA SECTION

On December 19, Charles D. Crowley gave an illustrated lecture on "Septic Tanks and Sewage Disposal." The following officers for 1923 were elected by the Section: Charles F. Crowley, chairman; Victor E. Levine, vice chairman; H. A. Senter, councilor; Robert Savage, J. A. Lund and W. D. Yodi, executive committee; and R. N. Perkins, secretary-treasurer.

R. N. Perkins, Secretary

# OREGON SECTION

At the January 27th meeting of the Section, held in Portland, Oreg., F. A. Gilfillan, of the Oregon Agricultural College, spoke on "Chemistry of Synthetic Drugs."

The regular monthly meeting of the Section occurred on February 24, at Corvallis, Oreg. The following papers were read: "Molecular Rearrangement," by E. C. Gilbert; and "The Effect of Temperature and Pressure on Hydrocarbon Vapor," by Floyd E. Rowland.

PAGE R. BOYLES, Secretary

### PHILADELPHIA SECTION

At the regular meeting of the Section, held on February 15, the section was addressed by Robert D. Bonney, of the Congoleum Company, Marcus Hook, Pa.

J. HOWARD GRAHAM, Secretary

# PITTSBURGH SECTION

The Local Section met in joint session with the American Ceramic Society on January 18, the following program being presented: "The Manufacture of Electrical Porcelain," by Marsden H. Hunt, of the Westinghouse High Voltage Insulator Co., Derry, Pa.; "Manufacture and Use of Enamel-Lined Apparatus," by Emerson P. Poste, of the Elyria Enameled Products Co., Elyria, O.; and "Manufacture and Properties of Oven Glass Cooking Ware," by Ralph F. Brenner, of the H. C. Fry Glass Co., Rochester, Pa.

# PUGET SOUND SECTION

On January 23, the Local Section held a joint meeting with the Industrial Bureau of Chamber of Commerce, Seattle, Wash., with the following program: "Recent Improvements in Wood Distillation," by O. F. Stafford, of the University of Oregon; and "A New Explosive from Sawdust," by William Dehn, of the University of Washington.

R. W. Ellison, Secretary

# PURDUE SECTION

At the regular meeting of the Section, held on January 18, B. B. Turner, of Indiana University School of Medicine, gave a lecture on "Life as a Chemical Phenomenon." On February 15, G. N. Hoffer, of the Purdue Experiment Station, spoke on

"Iron and Aluminum in the Corn Plant."

MARGUERITE G. MALLON, Secretary

### RHODE ISLAND SECTION

At the first meeting of the year, held on January 26, George Shannon Forbes, of Harvard University, spoke to the members of the Section, his subject being "Clock Reactions."

On February 20, T. B. Hine, of Edgewood Arsenal, Edgewood, Md., addressed the Section on the subject "Scientific By-Products of Chemical Warfare Research."

NELSON BARLOW, Secretary

### ROCHESTER SECTION

The 148th meeting of the Section occurred on January 22, when Victor C. Chambers, of the University of Rochester, addressed the members on the subject, "The Coloring Matter of Flowers."

On February 2, the members of the Section were invited to attend a lecture by E. V. McCollom, given before the Tuberculosis and Public Health Association of Rochester, N. Y., his subject being "Diet and Health."

The 149th regular meeting was held on February 5, when L. Ray Fergusen, of the Genesee Pure Food Co., LeRoy, N. Y., spoke on "Chemistry in the Jelly-Powder Industry."

At a joint meeting of the local Section with the Rochester Academy of Science, and Rochester Section of the Optical Society of America, held on February 19, Fred E. Wright, of the Geophysical Laboratory, Washington, D. C., spoke on "The Role of Experiment in Geology."

EARLE M. BILLINGS, Secretary

#### SAINT LOUIS SECTION

On February 7, H. E. Howe, editor of Industrial and Engineering Chemistry, spoke before the meeting of the Section, his subject being "Policy, Procedure, Finance and Plans of the Society."

H. A. Carlton, Secretary

# SAVANNAH SECTION

The regular monthly meeting of the Section occurred on January 11, when J. W. Daniels, of Savannah, spoke before the members on the subject, "Acidosis and Alkalosis."

HERBERT P. STRACK, Secretary

### SOUTHEAST TEXAS SECTION

On February 22, G. L. Fulgate, assistant city engineer of the City of Houston, Texas, addressed the Section, his subject being "Activated Sludge Process of Sewage Disposal." At this meeting, H. E. Howe, editor of *Industrial and Engineering Chemistry*, spoke on "Policy, Procedure, Finances and Plans of the Journal."

P. S. TILSON, Secretary

### SOUTHERN CALIFORNIA SECTION

The address before the Section, January 25, was by J. Jakobsen, on "The Refining and Hydrogenation of Edible Vegetable Oils." On February 15, F. B. Ortman spoke to the members, his subject being "Recent Developments in the Field of Ceramics."

MARK WALKER, Secretary

# SYRACUSE SECTION

On Saturday afternoon, January 13, the local Section enjoyed a pleasant trip through the gas plant of the Syracuse Lighting Co.

W. B. Hicks, Secretary

### TOLEDO SECTION

The 51st meeting of the Section occurred on January 20, when H. E. Howe, editor of Industrial and Engineering Chemistry, spoke on "Problems in Scientific Publication."

GUY E. VAN SICKLE, Secretary

# UNIVERSITY OF ILLINOIS SECTION

At the meeting of the Section, held on February 20, C. W. Balke, of the Fansteel Products Co., North Chicago, Illinois, addressed the members on the subject, "Ductile Tantalum."

D. T. Englis, Secretary

# VIRGINIA SECTION

At the 54th regular meeting of the Section, held on January 12, E. C. L. Miller, of the Medical College of Virginia, addressed the members, his subject being "Bacterio-phage."

On February 9, Graham Edgar, of the University of Virginia, spoke before the members of the Section, his subject being "Atomic Weights, Isotopes, and the Breaking up of Atoms."

W. G. Crockett, Secretary

## WASHINGTON, D. C. SECTION

The 337th meeting of the Section occurred on January 11, when R. C. Wells spoke on "Chemistry of the Sea."

The 339th meeting of the Section was held on February 8. E. V. McCollum spoke on "What has been Learned about Nutrition in a Decade."

J. B. Reed, Secretary

#### WESTERN NEW YORK SECTION

On January 10, the Section held a New Year's meeting at Canisius College.

On February 7, Rev. George L. Coyle, head of the Department of Chemistry, Holy Cross College, Worcester, Mass., addressed the members of the Section taking as his subject, "Activities of the American Chemical Society Committee on Society Procedure."

At the meeting held on February 15, T. A. Boyd spoke on "The Application of Chemistry to the Elimination of Fuel Knock."

R. W. Hess, Secretary

## WISCONSIN SECTION

At the regular meeting of the Section, held on January 10, W. Lee Lewis, of Northwestern University, spoke on "The Organic Chemist at Work."

The following officers for 1923 have been elected: J. H. Mathews, chairman; A. J. Marschall, vice chairman; F. Daniels, secretary-treasurer; L. F. Hawley and Victor Lenher, councilors.

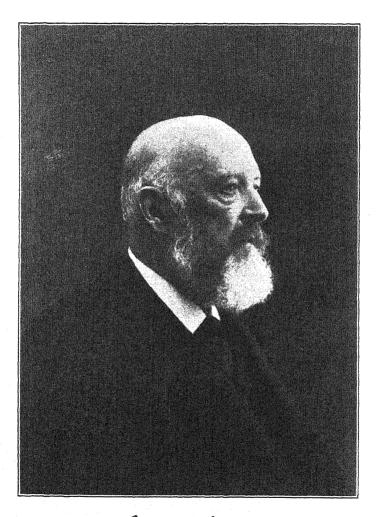

The regular meeting of the Section was held on February 14, when Joel Stebbins, professor of Astronomy at the Washburn Observatory, spoke to the members. His subject was "The Chemistry of the Stars."

FARRINGTON DANIELS, Secretary

## DECEASED

Arnold, Frank L., 32 School St., Woburn, Mass. Died, 1922.
Browning, Jr., Charles, c/o Southern Pacific Lines, Sacramento, Cal. Died, January 13, 1923.
Emerson, Herbert C., 145 Chestnut St., Springfield, Mass. Died, December, 1922.
Evans, Robert W., Mead Pulp & Paper Co., Chillicothe, O. Died, 1922.
Haines, Walter S., Rush Medical College, Chicago, Ill. Died, January 27, 1923.
Heilbrum, Alexander L., 1229 Webster Bldg., Chicago, Ill. Died July 11, 1922.
Huntington, Harwood, 419 S. Lorraine Blvd., Los Angeles, Cal. Died, 1923.
Lunge, George, 37 Carmenstrasse, Zurich, Switzerland. Died, January 3, 1923.
Mason, Francis Payne, 806 Marquette Bldg., Chicago, Ill. Died, Nov. 10, 1922.
Newberry, Spencer Baird, 818 Engineers Bldg., Cleveland, O. Died, Novelo, 1922.
Patterson, C. A., 1007 Broome St., Wilmington, Del. Died, July 26, 1922.
Tucker, Willis Gaylord, 80 Howard St., Albany, N. V. Died, April 22, 1922.

Höoff Baeyer

# ADOLF VON BAEYER

# 1835-1917

With the death on August 20, 1917, of Adolf von Baeyer, there passed the last of the great founders of organic chemistry. Less than two years before, on his eightieth birthday, he retired from his professorship, having up to that time carried on his full work in lectures and laboratory supervision. So active was he that it is doubtful if he would even then have given up his labors, had not the war depleted his laboratory of students and robbed him of his laboratory staff.

It was just before this time that his many American admirers were not a little shocked to find his name heading the list of German savants in the celebrated manifesto, calling on their colleagues outside of Germany to withhold judgment regarding the Belgian atrocities. He was known to have long been opposed to the militaristic spirit of Prussia, and it had been assumed that his refusal to accept the call to Berlin, the home of his childhood, as successor of Hofmann, was inspired by this disapproval. But in his old age, it is hardly surprising to find him testifying to his loyalty to that *Vaterland*, under which he had lived for well-nigh four score years. It was an alphabetical mischance that gave the manifesto publicity as that of "Adolf von Baeyer and others." We may believe that he was well content to retire to his beautiful home on the Starnbergersee, and pass the few remaining months of his life in well-earned quiet and comfort.

Comparatively few Americans studied with Baeyer. At the time when his brilliant work on indigo would naturally have begun to attract students to Munich, Victor Meyer was at Göttingen and Ostwald was beginning his great activity at Leipzig, Hofmann and numerous others were at Berlin, and the stream of American students was never largely diverted to the south; few of us knew anything of the personality of the man. One, however, whose good fortune it was to spend a year in his laboratory has written me the following:

"He impressed me at the time I was in his laboratory, and I retained that impression afterwards, as being a man of a great deal of personal dignity. He was handsome, with a large head and very expressive eyes. As regards the students in the laboratory he was rather distant, but very gracious and approachable to the English and Americans. His lectures, which were brilliantly illustrated by experiments, were models of simplicity; he always emphasized the important general reactions and properties of substances, and appealed in general to those who had but little previous knowledge of the subject. In this respect he was the very opposite of Victor Meyer, who lectured as if the class consisted entirely of students familiar with organic chemistry from previous training. Professor Baeyer was good enough to write me from time to time, and I saw him again in 1913, when he was ready to retire from active duties. In spite of his advanced age, he was remarkably familiar with all the modern literature. There was a strain of mysticism in his talk, which indicated somewhat that he was losing his sense of logic."

Adolf von Baeyer was born at Berlin, October 31, 1835, his father being at the time chief of the Geodetic Institute, and we are not surprised to find that even as a child he was interested in natural science. His private laboratory at home seems not always to have been appreciated, for Paul Heyse, who was an intimate in the family, wrote:

"Es stinkt in diesem Huss gar sehr, Das kommt vom Adolf Baeyer her."

He began his serious chemical studies under Bunsen at Heidelberg, and later was under Kekulé, whom he followed to Ghent. He took his degree of Ph.D. at Berlin in 1858, and there came under the influence of Hofmann, with whom he worked as Privat-dozent, and in 1866 he became "extraordinary" professor. It was during this period that he carried on his studies on organic arsenic compounds, inspired by Bunsen, and on which he made his doctor's thesis. At this time also he did fundamental work on the constitution of uric acid, actually synthesizing "pseudo-uric acid" (the ureid of alloxan). While his view of the structure of uric acid was somewhat at fault, he rightly believed that if he could remove a molecule of water from pseudo-uric acid he would have uric acid. In spite of great efforts he failed to accomplish this dehydration, and only in 1888 did Emil Fischer, trained in Baever's own laboratory, succeed, by dissolving pseudouric acid in fused oxalic acid, in carrying out this operation and completing the synthesis along Baeyer's lines. During this period, also, he began his work on the structure and synthesis of indigo, which was brought to completion a quarter of a century later.

In 1872, Baeyer was called from Berlin to head the department of chemistry in the new University of Strasburg. In the 3 years he remained here his work upon the phthaleins was perhaps the most important, but more far-reaching was the impetus he gave to Emil Fischer, the greatest of his students. Caro also began his work with him during this period.

Strasburg was, however, soon to be deprived of his services, for in 1875 he was chosen Liebig's successor at Munich, where he founded the *Chemisches Institut*. Here his greatest work was done, work great in the importance and extent of his researches and even greater in the stream of students he sent forth, a stream of those who have largely made organic chemistry what it is to-day.

It would require a book to give a review of Baeyer's contributions to organic chemistry. His *Gesammelte Werke*, published in Braunschweig in honor of his seventieth birthday, occupy two volumes, and these works are classified under no less than 17 different heads. There was hardly a field in the organic chemistry of the last century that he did not cultivate and leave the richer for his work. Of far-reaching importance were his contributions to the structure of benzene. He was probably the first to propose a symmetrical structure for the molecule, basing his argument

on the formation of mesitylene from acetone; his work on oxyterephthalic acid and the hydrophthalic acids settled the case against Ladenburg's prismatic formula, as well as against the diagonal formula of Claus. His own "centric" formula, perhaps first suggested by Armstrong, and widely adopted as a tentative solution of the problem, was a keen and successful effort to "beg the question" in a scientific way. He saw clearly that no one formula would account for all the reactions. The idea that the same molecule could exist with different constitutions at different times or under different circumstances, had been earlier introduced by Baeyer under the name of pseudomerism, to account for the then puzzling anomalous reactions of aceto-acetic ester, and was later developed under the name of tautomerism, now a well-recognized phenomenon of chemistry. It was his work in connection with the structure of benzene that led him later to formulate his strain theory (Spannungstheorie) of the double and triple bond, especially between carbon atoms, a theory which has exercised an important influence on the development of chemistry.

Baeyer was always closely identified with the Deutsche Chemische Gesellschaft, and gave the opening paper at its first meeting, January 27, 1868. his subject being the reduction of indigo to indole by means of zinc dust. This was the first of many papers before the society, in which he portrayed, for the next score of years, his efforts to solve the problem of first the constitution and then the synthesis of indigo. It is this work by which Baever is best known to the world outside. It is interesting to recall that even after Baeyer had completed this work, it was still a mooted question whether synthetic indigo was really the same as that produced by the plant. similar controversy had raged regarding natural and synthetic alizarin, the first step in elucidating the constitution of which had been made possible to Graebe and Liebermann, by the use of the zinc dust reaction introduced by Baeyer. The differing color reactions of benzene from benzoic acid and that from coal tar was another case in point, and I recall that it was often discussed in the Göttingen Laboratory in the early 80's. It was there that Victor Meyer's discovery of thiophene in commercial benzene revealed the importance of minute amounts of impurities in the natural substances, and settled the controversy regarding the absolute identity of natural and synthetic products. All of this may justly be considered an outgrowth of Baeyer's work.

Though at no little distance from Berlin, the headquarters of the Gesell-schaft, Baeyer was always in close touch. His many papers in the Berichte constitute alone no mean history of the rise and development of organic chemistry. He was repeatedly honored by the Society by election to its offices, and often greeted officially on the various anniversary days of his life. It was on the occasion of the celebration of his seventieth birthday that van't Hoff, then president of the Gesellschaft, and Liebermann

presented him with an address, in which, after alluding to his work on indigo, his services to organic chemistry were well summarized, as follows:

"But even these great attainments constitute but a limited portion of the work accomplished through your marvelous intuition and incomparable experimental skill. As by analysis you have unlocked the secrets of uric acid, isatin and mellite, so on the other hand you have taught us by synthesis the preparation, now of important compounds such as neurine, and now of whole series of condensation products, among which are found the phthaleins, the beautiful fluorescein and eosin, gallein, cerulein and quinizarin. Cinnamic acid led you on the one hand to indigo, on the other to the synthesis of quinoline and rings containing nitrogen. Linked with this, your sharp-sighted strain theory as well as your theories of pseudomerism and of *cis-trans*-isomerism, have revealed to us new laws that are now well recognized. Proceeding from the latest explanations of the benzene nucleus, you are opening up the nature of the hydro-aromatic compounds and the fundamental structure of the terpenes, whose simpler members you have been happily enabled to synthesize. It is only natural that we should be looking with eager anticipation to the progress of your latest work, which has for its aim nothing less than the clearing up of the connection between color and constitution."

Baeyer had nearly reached his three score years and ten when, with Villiger, he began his far-reaching work on the oxonium bases and the quadrivalent nature of oxygen, and at about the same period came the discovery of triphenylmethyl, the investigation of which has been so largely carried on by Gomberg.

Baeyer's was a life of great achievements, but any notice of him would be incomplete which did not emphasize his extraordinary power of inciting his students to follow in his footsteps. A roll of those who have been students in his laboratory would include almost every professor of chemistry in the German universities from 1880 to 1910. Claisen, Curtius, Emil and Otto Fischer, Graebe, Knorr, Liebermann, Victor Meyer and Willstätter are but a few among many. As leaders in industrial chemistry, too, his students have played no insignificant part, as witness the work of Caro and of Duisberg.

Adolf von Baeyer was a great chemist; great as a student, great as an investigator, great as a teacher; the American Chemical Society honored itself when his name was placed upon its roll of Honorary Members.

JAMES LEWIS HOWE

# Proceedings

## COUNCIL

The committee to suggest rules governing the selection of the chemist who is annually deemed most worthy to receive the prize given by the Allied Chemical and Dye Corporation, as published on page 88 of the Proceedings for 1922, consists of Edgar F. Smith, chairman, Charles F. Chandler, Edward W. Morley, Ira Remsen, and F. P. Venable. They will report at the New Haven meeting.

# REPORT OF THE TREASURER

The Treasurer begs your indulgence for the delay in making his report, due to his absence.

The Auditors' Report was published in the March Journal. There has been no change in the permanent securities held by the Society excepting the expiration of \$10,000 Victory Loan Bonds on December 15. Since the beginning of this year this amount has been replaced in the fund by the purchase of Liberty Bonds.

An examination of the Auditors' Report shows total receipts from the usual sources of about \$308,000 and total disbursements of about \$298,000, leaving a net excess of receipts over disbursements of \$9,730.44. It should be noted, however, that in the Auditors' Report the receipts from Advertising are included for 13 months. It has been customary heretofore to report December receipts, for example, as of January first date. For this year, however, the December 1921 receipts are reported as of January first date, and by a change in method December 1922 receipts are reported as of December 30 date and so included in the records for the year 1922. If we deduct the receipts for one December we find that our working profit would have been slightly less than \$2,000.

It may be of interest to some members to give a percentage analysis of our receipts and dispursements.

RECEIPTS of \$308,000 were divided as follows, in round numbers:

Members' Dues	57 %
Advertising, net	29 %
Non-Member Subscriptions	7 %
Interest	2.3%
Back Numbers	2 %
Postage	1.3%
Reprints	1.2%

DISBURSEMENTS of about \$298,000 were distributed as follows, percentages being given as percentages of receipts:

Chemical Abstracts	32%
Industrial Journal	23%
Journal A. C. S	15%
Printing Advertising	10%
Secretary's Office	7%
News Service	3%
Local Sections	3%
Treasurer's Office	1%
Surplus	30%

Other items are less than 1%.

We are rapidly approaching the day when the cost of the Industrial Journal plus the cost of the advertising printed in it will be covered by the receipts from advertising in that journal plus the receipts of non-member subscriptions to the journal. We have not yet quite reached the point, but are near it.

For the year 1923 the Budget as drawn by the Directors shows an excess of proposed disbursements over expected income. As the price of paper shows indications of rising further, great care will be needed this year to come through the year with a balanced budget.

JOHN E. TEEPLE
Treasurer

March 12, 1923

Dr. John E. Teeple, Treasurer
American Chemical Society
50 East 41st Street,
New York City

## DEAR SIR:

As requested by you we have this day made an inspection and count of the securities held by the American Chemical Society as investments; also those held as trust funds, as such securities are enumerated in Exhibit "A" of our report, dated January 18th, 1923.

A certified list of these securites was furnished us by you at the time of rendering our report, which list has now been verified by an inspection and count of the securities. All of the securities were found to be on hand, or properly accounted for.

Yours very truly, McCulloh & Brown

# MEMBERS ELECTED BETWEEN FEBRUARY 15 AND MARCH 15, 1923

Abaya, Vincente S., 6235 University Ave., Chicago, Ill. Abbott, Marc A., 1555 Jackson St., San Francisco, Cal. Acheson, George Wilson, 480 Clifton Ave., Newark, N. J. Ackerson, Clifton W., College of Agriculture, Lincoln, Neb. Allen, A. W., 1424 Scenic Ave., Berkeley, Cal. Armendt, B. F., Vanderbilt University, Nashville, Tenn. Ashecroft, Edgar A., Waye, W. Ashburton, S. Devon, England. Axling, Bjorn, 4866 North Rockwell St., Chicago, Ill. Baechler, Roy H., City Y. M. C. A., Madison, Wis. Bailey, Wm. J. A., 36 N. 20th St., East Orange, N. J. Baldwin, Fred Hixon, Bergenport Chemical Works, Bayonne, N. J. Bamber, M. Kelway, The Laboratory, Hyde Park Corner, Colombo, Ceylon. Barackman, Rufus A., New Prague, Minnesota. Baudisch, Oskar, Sterling Chemical Lab., New Haven, Conn. Bayliss, W. S., Filtrol Co., 326 A. G. Bartlett Bldg., Los Angeles, Cal. Bee, O. E., 552 Patterson Ave., Akron, Ohio. Berliner, J. T. T., 1471 Irving St., Washington, D. C. Berry, Chas. Leslie, Mill St., Orono, Maine, Box 355. Blackmore, C. F., 118 5th Ave., New York City. Blanchard, Walter O., 87 Wallace St., Somerville, Mass. Wolfson, Jacob. National Aniline & Chem. Co., 351 Abbott Road, Buffalo, N. Y.

Wood, Harry A., Santa Elena, Entre Rio, Argentine Republic.

Work, Harold K., 835 Livingston Hall, Columbia Univ., New York City.

Working, Earl B., Desert Laboratory, Drawer L., Tucson, Ariz.

Wright, E. Katharine, North Caroline College for Women, Greensboro, North Carol.

Wylde, Edward P., 6330 Kimbark Ave., Chicago, Ill.

Yant, William P., 4740 Friendship Ave., Pittsburgh, Pa.

Yen, Louis, 110 Cook St., Ithaca, N. Y.

#### CORPORATION MEMBERS ELECTED

British American Oil Co., Ltd., Royal Bank Building, Toronto, Canada. Corning Glass Works, Corning, N. Y. Hudson Coal Company, 206 East Market St., Scranton, Pa. Industrial Fibre Company, West 98th and Walford Ave., Cleveland, Ohio.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

### AKRON SECTION

The first meeting of the Section was held on February 26, when Harry N. Holmes, of Oberlin College, spoke on "Emulsions."

W. J. Kelly, Secretary

### CALIFORNIA SECTION

The 137th regular meeting of the Section occurred on March 2, at the Engineers' Club, San Francisco, Cal. Two papers, as follows, were delivered: "Equilibria in Solutions Containing Carbonates and Chlorides of Sodium and Potassium," by W. C. Blasdale, of the University of California; and, "Manufacture and Purification of Oil Gas," by George H. West, chemical Engineer, of San Francisco.

L. H. DUSCHAR, Secretary

#### CHICAGO SECTION

At the regular meeting of the Section, on February 23, William Hoskins, of Chicago, addressed the members on the subject, "Experiences of a Consulting Chemist." The usual group meetings were held.

S. L. Redman, Secretary

## COLORADO SECTION

The Feburary meeting of the Section was held on the 28th at the Denver Public Library, Denver, Colo. A paper, entitled "Some Aspects of the Rare Earths," by Earle Engle, of Denver University, was presented.

RUTH B. VERTREES, Secretary

## CONNECTICUT VALLEY SECTION

On March 10, Ellwood Hendrick, consulting editor of Chemical and Metallurgical Engineering, New York City, addressed the members of the Section, his subject being "Obligations in Chemistry."

PAUL SEREX, JR., Secretary

## CORNELL SECTION

At a meeting of the Section, held on March 19, Victor F. Hess, of the United States Radium Corporation, addressed the members, his subject being "Radium Emanation and its Purification."

On March 23, A. C. Boniface, of the Foamite Childs Corporation, delivered an illustrated lecture before the Section, his subject being "The Use of Froth for Fighting Fires."

F. E. Hance, Secretary

## DELAWARE SECTION

The regular monthly meeting of the Section, held on March 21, was addressed by Marston T. Bogert, of Columbia University. His subject was "Perfumes, Natural and Synthetic."

J. W. Stillman, Secretary

#### EASTERN NEW YORK SECTION

On March 9, Walter Rosenhain, director of the metallurgical department of the National Physical Laboratory of England, delivered a lecture before the meeting of the Section. His subject was "The Relation Between the Properties and Structure of Metals."

E. H. Darby, Secretary

#### GEORGIA SECTION

The following officers have been elected by the Section for the year 1923: Chairman, J. F. Sellers; vice chairman, J. S. Brogdon; secretary-treasurer, L. B. Lockhart; and councilor, W. P. Heath.

L. B. LOCKHART, Secretary

#### INDIANA SECTION

On February 13, Neil Waterbury, of the Link Belt Co., spoke before the members of the Section, his subject being "Malleable Cast Iron and Its Properties." At the meeting of February 20, Frank B. Wade, of Shortridge High School, talked on "Color in Precious Stones."

The regular monthly meeting of the Section occurred on March 9, at Indianapolis, Ind. L. M. Tolman, technical director, Wilson & Company, Chicago, Ill., spoke on "The Value of Meat in the Diet."

WILLIAM HIOBURG, Secretary

## KANSAS CITY SECTION

At a meeting of the Section, held at Lawrence, Kansas, March 16, Roger Adams, professor of organic chemistry, University of Illinois, spoke on "Synthetic Drugs." On the same day, Prof. Adams addressed a meeting in Kansas City, taking as his subject "Recent Developments and Recent Patents in the Field of Organic Chemistry."

LEE E. CLARK, Secretary

#### LEXINGTON SECTION

The S6th regular meeting of the Section occurred on March 14, when O. M. Shedd, research chemist in the Kentucky Agricultural Experiment Station, Lexington, Ky., spoke on "The Relation of Sulfur to Soil Fertility." E. L. Jackson, Secretary

## LOUISIANA SECTION

On February 21, H. E. Howe, editor of Industrial and Engineering Chemistry, addressed the Section, his subject being "Publication Problems and Society Procedure."

H. R. STEVENS, Secretary

# LOUISVILLE SECTION

The January meeting of the Section was held on the 18th, and was addressed by W. R. Jillson, director of the Kentucky Geological Survey. His subject was "The Geology of Oil and Gas in Kentucky."

C. E. Geiger, Secretary

## MAINE SECTION

At the regular monthly meeting of the Section, held on March 9, E. W. Manter, of the Westinghouse Electric and Manufacturing Co., spoke on "Industrial Lighting (Illustrated)."

N. E. WOLDMAN, Secretary

#### MIDLAND SECTION

The 16th regular meeting of the Section was held on February 21, when E. R. MacLaughlin of the Dow Chemical Co., spoke on "Evaporator Studies."

John A. Gann, Secretary

#### MINNESOTA SECTION

On January 30, H. E. Howe spoke before the meeting of the Section, his subject being "Publication Problems and Society Procedure."

L. M. Henderson, Secretary

# NEBRASKA SECTION

The 107th meeting of the Section occurred on February 3, when H. E. Howe, editor of Industrial and Engineering Chemistry, spoke on "Publication Problems and Society Procedure."

S. B. Arenson, Secretary

## NEW YORK SECTION

The regular meeting of the Section was held on March 9. The Nichols Medal was presented to Thomas Midgley, of the General Motors Research Corporation. The program was as follows: "Introductory Remarks," by C. A. Browne, chairman of the Section; "Midgley and his Work," by W. D. Bancroft, of Cornell University; "Presentation of the Nichols Medal," by Charles H. Herty, president of the Association of Synthetic Organic Chemical Manufacturers; and acceptance and address by Thomas Midgley, "Some Fundamental Relations Among the Elements and Compounds as Regards the Suppression of Gaseous Detonation."

Benjamin T. Brooks, Secretary

## NORTHEASTERN SECTION

The 183rd meeting of the Section occurred on March 9, when Otto Folin, of the Harvard Medical School, spoke on "The Metabolism of Uric Acid."

E. B. MILLARD, Secretary

#### NORTHERN INDIANA SECTION

On February 21, R. E. Wilson, director of research, Standard Oil Co., Whiting, Ind., spoke to the Section, his subject being "The Mechanism of the Corrosion of Iron and Steel."

V. C. Bidlack, Secretary

#### OMAHA SECTION

The members of the Section were invited to be the guests of The Cudahy Packing Company to attend a dinner, scientific program, exhibit, and laboratory tour on March 6. At the scientific meeting the following program was presented: "Historical Aspects of the Meat Packing Industry," by C. A. Stewart; "The Role of Bacteriology in the Meat Packing Industry," by Millard Langfeld; "The Role of Chemistry in the Meat Packing Industry," by P. G. Daschavsky; "The Bacteriology of Meat Curing Solutions," by W. S. Sturgis; and "The Chemistry of Meat Curing Solutions," by H. L. Cox.

R. N. PERKINS, Secretary

# PHILADELPHIA SECTION

At the regular monthly meeting of the Section, held on February 15, the following papers were presented: "The Artificial Silk Industry," by Hugo Schlatter; and "A Rapid Testing Method for Paint and Similar Plastics," by Robert D. Bonney.

On March 15, Oswald Schreiner, of the Department of Agriculture, addressed the meeting of the Section, his subject being "Chemistry and Agriculture." At the same meeting, Charles C. Roberts spoke on "A Clever Method for Elimination of Moisture."

J. HOWARD GRAHAM, Secretary

#### PITTSBURGH SECTION

The annual smoker of the Section was held on February 22 at the U. S. Bureau of Mines auditorium, Pittsburgh, Pa. An interesting program of entertainment was provided.

E. S. STATELER, Secretary

#### PUGET SOUND SECTION

At the regular monthly meeting of the Section, G. C. Howard, of Seattle, Wash., spoke on "Tannin, Cork and other Products from Bark." R. W. Ellison, Secretary

#### RHODE ISLAND SECTION

On March 6, Ralph H. McKee, of Columbia University, lectured before the members of the Section. His subject was "Future Sources of Gasoline: Will the Supply Hold Out?"

Nelson Barlow, Secretary

#### ROCHESTER SECTION

The 152nd regular meeting of the Section, held on March 19, was addressed by Breese Jones, his subject being "Protein Factor in Nutrition (Illustrated)."

ERLE M. BILLINGS, Secretary

# SAINT LOUIS SECTION

The following program was presented at the meeting of the Section held, on March 5: "The Standardization of Chemical Apparatus," by B. F. Glasser, of the Henry Heil Chemical Company; and "Some Observations on the Situation in Europe," by Gaston Du Bois, of the Monsanto Chemical Works.

On March 24, E. C. Franklin, president of the American Chemical Society, gave a lecture before the members, his subject being "The Ammonia System of Compounds."

H. A. CARLTON, Secretary

# SAVANNAH SECTION

At the regular meeting of the Section, held on Feburary 14, V. H. Bassett spoke on "The Life and Work of Pasteur." This was followed by a talk on "Industrial and Engineering Chemistry," by H. E. Howe, editor.

Herbert P. Strack, Secretary

#### SOUTHERN CALIFORNIA SECTION

The March meeting of the Section was held on the 16th, when E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Compounds."

MARK WALKER, Secretary

## SOUTH JERSEY SECTION

The regular meeting of the Section was held on March 15, when John H. Muller, of the University of Pennsylvania, spoke on the subject, "Germanium."

W. FLETCHER TWOMBLY, Secretary

# SYRACUSE SECTION

On February 23, John A. Palmer, of Auburn, N. Y., addressed the members of the Section. His subject was "Linoleum and Drying Oils."

At the regular meeting held on March 9, Harry Essex, professor of Physical chemistry, Syracuse University, spoke to the members on the subject of "Isotopes."

W. B. HICKS, Secretary

#### TOLEDO SECTION

The regular March meeting of the Section, held on March 7, was addressed by T. A. Boyd, of the General Motors Research Corporation. His subject was "The Application of Chemistry to the Elimination of the Fuel Knock."

Guy E. Van Siere, Secretary

#### UNIVERSITY OF MICHIGAN SECTION

On February 27, E. H. Kraus spoke before the members of the Section, his subject being "Some Recent Tendencies in Mineralogy."

At the regular March meeting of the Section, held on the 13th, J. E. Harris, of the Western Electric Company, spoke on "The Electron at Work."

C. C. MELOCHE, Secretary

#### UNIVERSITY OF MISSOURI SECTION

The 114th meeting of the Section, held on February 6, was addressed by H. E. Howe, editor of Industrial and Engineering Chemistry, his subject being "Publication Problems and Society Procedure."

H. E. French, Secretary

## VERMONT SECTION

At the regular monthly meeting of the Section, held on February 16, P. Conant Voter, of Middlebury College, spoke on "The Atomic Weight of Arsenic." At the same meeting, Elbridge C. Jacobs, of the University of Vermont, spoke on "Origin of the Vermont Talc Deposits."

E. C. Jacobs, Secretary

## VIRGINIA SECTION

On March 9, at the Medical College of Virginia, Richmond, Va., W. M. Corse, of the National Research Council, addressed the Section, his subject being "Nickel, Its Metallurgy and Uses."

W. G. Crockett, Secretary

## WASHINGTON, D. C. SECTION

The 339th meeting of the Section occurred on March 8, when Leason H. Adams, of the Geophysical Laboratory, spoke on "Reactions and Properties of Substances at High Pressures."

J. B. Reed, Secretary

## WESTERN NEW YORK SECTION

"Blue Eyes and Blue Feathers," was the subject of a lecture by W. D. Bancroft, of Cornell University, before the local Section, at its meeting held on March 8.

R. W. HESS, Secretary

## WISCONSIN SECTION

The 122nd regular meeting of the Section was held on March 14, when George I. Kemmerer spoke on "A Scientific Study of Fresh Water Lakes."

FARRINGTON DANIELS, Secretary

# Proceedings

# GENERAL MEETING MINUTES

The 65th general meeting of the American Chemical Society was held at NewHaven, Connecticut, Monday, April 2 to Saturday, April 7, 1923, inclusive. The Council Meeting was held on the 2nd, the general meeting on the morning and afternoon of the 3rd, and divisional meetings all day Thursday and Friday. Excursions took up the whole of Saturday. These excursions covered numerous manufacturing plants not only in New Haven but in the surrounding cities and towns. A feature of the meeting was the dedication of the Sterling Chemistry Laboratory which was under the auspices of Yale University and to which all day Wednesday was given. A second Council meeting was held on Wednesday afternoon with the approval of the authorities at Yale. Full details of the meeting will be found in the May, 1923, issue of *Industrial and Engineering Chemistry*. The registration was slightly over 1200, with approximately 100 ladies attending the meeting. A considerable number of members, estimated at 200, the meeting who, coming in the last two days, did not register, not realizing the necessity attended of registering and paying the registration fee to help carry the expense of the meeting, as voted by the Council.

A general public address entitled "Chemistry and the Public" was given by Francis P. Garvan on Tuesday morning. Sir J. J. Thomson addressed the Society on Wednesday evening on "The Unity of Physics and Chemistry."

At the general business meeting held Tuesday morning resolutions and tribute were presented to our late Honorary Member, Edward W. Morley. These resolutions will be found printed in the Council Minutes.

At the general meeting on Tuesday afternoon the following general papers were presented:

Carl L. Alsberg. Chemistry and Our Food Resources.

C. O. Johns. The History and Status of Chemistry Petroleum Research.

H. E. Barnard. The Baker Turns to the Chemist.

Oskar Baudisch. The Influence of Light on Inorganic Material and Life Processes.

W. O. Mitscherling. Cellulose Silk.

Arthur Hirschfelder. The Influence of Modern Chemistry on Pharmacology.

The following Divisions and Sections met: Divisions of Agricultural and Food Chemistry, Biological Chemistry, Cellulose Chemistry, Dye Chemistry, Industrial and Engineering Chemistry, Chemistry of Medicinal Products, Organic Chemistry, Petroleum Chemistry, Physical and Inorganic Chemistry, Rubber Chemistry, Sugar Chemistry, Water, Sewage and Sanitation; Sections of Chemical Education, Gas and Fuel Chemistry, and History of Chemistry. Further details of their meetings will be found in the May issue of *Industrial and Engineering Chemistry*.

On Monday evening a complimentary banquet to the Council, attended also by many members of the Society and a large number of the members of the New Haven Chamber of Commerce, was given by the New Haven Chamber of Commerce to the Council at the Taft Hotel. Many speakers of prominence addressed the members. The banquet was an occasion long to be remembered by those who were fortunate enough to attend.

On Tuesday evening a very enjoyable smoker was tendered by the New Haven and Connecticut Valley Sections in the dining hall of Yale University. The special feature was a dramatical allegory entitled "Iono and Faradette, A Chemical Ballet,"

written by Daniel Caldwell Long and John Arrend Timm. The play was beautifully staged, was extremely interesting, and was thoroughly appreciated by all present.

At the dedication exercises at Sterling Chemistry Laboratory the gathering was addressed by Past President Edgar F. Smith on "The History of Chemistry in America with Special Reference to Yale." The building was presented to the University by the Sterling Trustees and accepted by President Angell with proper reply. President Franklin replied also for the Society when it was presented to the Society for its use during the meeting. The University tendered a complimentary luncheon to all members and guests the same day at one o'clock in the University dining hall.

On the evening of the 5th an indoor polo game was staged for the members in the Yale Armory. On the 6th a reception and dinner was given to the members and guests in Woolsey Hall. The scientific program was extensive, 375 papers being presented.

CHARLES L. PARSONS, Secretary

# DIRECTORS' MINUTES

The Directors of the American Chemical Society met in the Hotel Taft, New Haven, Conn., Monday, April 2, 1923, at 10:30 p.m., with E. C. Franklin in the Chair, and W. D. Bancroft, William Hoskins, John E. Teeple, and C. L. Parsons present.

The Treasurer reported the following transactions:

- Dec. 15, 1922 \$10,000 Victory Liberty Loan Bonds, called, paid to-day.
- Dec. 15, 1922 \$25,000 Note dated 11/9/22, Farmers' Loan & Trust Co. paid to-day— Total \$25,118.75.
- Dec. 15, 1922 Bought \$800 Fourth Liberty Loan Bonds, investing Priestley Memorial Funds—Total \$795.65.
- Jan. 5, 1923 Bought \$10,000 Third Liberty Loan Bonds, replacing the \$10,000 Victory called Bonds 12/15/22—Total \$10,041.90.
- Jan. 13, 1923 Bought \$10,000 Victory Liberty Bonds, due May 20, 1923, Temporary Investments—Total \$10,079.40.
- Jan. 26, 1923 Bought \$10,000 Victory Liberty Bonds, due May 20, 1923, Temporary Investments—Total \$10,092.56.
- Mar. 29, 1923 Bought \$600 par Liberty Third Bonds—Life Membership Fund— Total \$591.51.

It was voted that the Treasurer be authorized to expend not to exceed \$600.00 in furnishing a booth at the Chemical Exposition and arranging a proper exhibit therein.

It was voted, in view of the fact that accounts have been fully audited and much useless material accumulates, that the Treasurer be authorized to destroy obsolete records, canceled checks, etc. of his office prior to the year 1921 and to do likewise in future years for similar records of the years prior to two years previous to the year current.

It was voted to rescind the vote of the Directors passed on November 22 regarding special reprints such as theses and that hereafter these special reprints be handled by the printer as heretofore but that the prices charged by the printer be subject to revision by the Society.

CHARLES L. PARSONS, Secretary

## ADVISORY COMMITTEE MINUTES

The Advisory Committee met at the Hotel Tast, New Haven, Connecticut, at 10.30 A.M., Monday, April 2, 1923, with President Franklin in the Chair and Messrs. H. E. Howe, A. B. Lamb, Wm. McPherson, W. A. Noyes, Edgar F. Smith, and Charles L. Parsons present,

A communication was read from the National Conference on Pharmaceutical Research, requesting the American Chemical Society to appoint a delegate or "unofficial observer" to the Asheville meeting of this Conference to be held in Asheville, N. C., September 1, 1923. The President, with the advice of the Committee, appointed Oliver Kamm as the delegate to this meeting.

A communication was received from A. H. Nuckolls of the Underwriters' Laboratories, transmitting the request of George W. Booth, Chief Engineer, National Board of Fire Underwriters, and Chairman of the National Fire Protection Association Committee on Hazardous Chemicals and Explosives, requesting the coöperation and assistance from the American Chemical Society and the appointment of a committee to assist in this work. After careful consideration, the President, with the advice of the Committee, appointed a committee to consist of Charles E. Munroe, H. LeB. Gray, A. H. Nuckolls, James A. Rafferty, Fred C. Zeisberg.

President Franklin, with the advice of the Committee, appointed W. D. Bigelow, H. P. Cady, and F. J. Moore to represent the American Chemical Society in the Division of Chemistry and Chemical Technology of the National Research Council for the term ending 1926.

A communication was received from the Societe D'Encouragement Pour l'Industrie Nationale requesting the appointment of a delegate to their convention in Paris from the 7th to the 10th of June, 1923. The President himself being unable to attend, with the advice of the Committee, he appointed Professor R. E. Swain of the University of California as the delegate of the Society thereto.

A letter to the Secretary from the Secretary of the American Engineering Standards Committee, dated March 27th, regarding the question of abbreviations and symbols, was presented to the Advisory Committee. The Committee was of the opinion that it will be quite impossible for the American Chemical Society to effectively coöperate on chemical abbreviations and symbols with others than international chemical and physical societies and instructed the Secretary to inform Mr. Agnew that while we wish in every way to be helpful, the Committee felt that the matter of chemical abbreviations and symbols was a question for the chemical societies of the world, but that they were ready to be of assistance at any time and would communicate with his Committee concerning the results that have been obtained by many years of careful study of these specifically chemical matters.

The Committee voted to recommend to the Council that certain letters in the possession of the Secretary, such as the acceptances of Honorary Membership, be donated to the collection of Edgar F. Smith for proper preservation.

A communication from W. D. Collins was presented to the Advisory Committee regarding the use of names of certain manufacturers that he had used in his report. The Committee expressed its opinion that there was no reason why these names should not be included in his report.

## ADVISORY COMMITTEE MEETING

## April 3, 1923

The Committee met in Byers Hall on Tuesday afternoon, April 3, 1923, at 5.30 P.M., with E. C. Franklin in the Chair, and Messrs. Comey, Howe, McPherson, Noyes and Parsons present.

The Committee voted to call an additional Council meeting on the afternoon of Wednesday, permission having been obtained from the officials of Yale University to thus infringe upon their program.

The Committee voted to recommend to the Council that the Monday preceding the opening of general meetings be kept free for Council business and that no complimentary dinner to members of the Council be held in future.

A request was received from the Federated American Engineering Societies for the appointment of a delegate to a Committee on Coal Storage. The President with the advice of the Committee, appointed S. W. Parr thereto.

#### ADVISORY COMMITTEE MEETING

# April 5, 1923

A meeting of the Advisory Committee was held at the Graduate Club, Yale University, Thursday noon, April 5, 1923, with E. C. Franklin in the Chair and Messrs. H. E. Howe, W. A. Noyes, Edgar F. Smith, and Charles L. Parsons present.

The question of geographical distribution of Directors, the question of personnel of an Executive Committee, and the question of changes in Council representation, referred to it by the Council were discussed freely. The Secretary was instructed to formulate the views of those present, to present them to the other members of the Advisory Committee, and to have them in form for final approval of the Advisory Committee and presentation to the Council at the Milwaukee meeting.

As directed by the Council, President Franklin, with the advice of his Committee, appointed M. T. Bogert, Chairman, W. Lee Lewis, R. W. Neff, O. F. Stafford, and C. E. Coates a special Committee to consider the subject of inter-sectional meetings and all its bearings and to formulate a working plan to be submitted to the Council for consideration at its next meeting.

By direction of the Council, President Franklin, with the advice of the Committee, appointed Wm. Hoskins, Chairman, A. D. Little, and James Kendall a Committee to consider the whole matter enhancing the value placed on membership and to make special recommendations to the Council for final action at the Milwaukee meeting.

The Committee then adjourned. Charles L. Parsons, Secretary

# COUNCIL MINUTES

The Council of the American Chemical Society met in Byers Hall, Yale University, New Haven, Connecticut, on April 2, 1923, at 2.30 p.m., with President E. C. Franklin in the Chair and the following Councilors present:

Ex-Officio.—Wilder D. Bancroft, Marston T. Bogert, A. M. Buswell, E. J. Crane, G. J. Esselen, Jr., Charles H. Herty, W. F. Hillebrand, William Hoskins, J. S. Hughes, Arthur B. Lamb, A. D. Little, Arthur A. Noyes, H. A. Noyes, W. A. Noyes, Charles L. Parsons, Edgar F. Smith, John E. Teeple, John Arthur Wilson, Robert E. Wilson.

Councilors-at-Large.—Roger Adams, C. L. Alsberg, A. M. Comey, H. E. Howe, Lauder W. Jones,

Councilors-at-Large.—Roger Adams, C. L. Alsberg, A. M. Comey, H. E. Howe, Lauder W. Jones, Wm. McPherson, Allen Rogers.

Local Sections.—Akron, R. P. Dinsmore, W. J. Kelly (subs. for H. E. Simmons). Ames, W. F. Coover. California, C. W. Porter (subs. for J. H. Hildebrand). Central Texas, J. R. Bailey. Chicago, D. K. French (subs. for W. R. Smith), Herbert N. McCoy, Carl S. Miner (subs. for Paul Van Cleef), A. V. H. Mory (subs. for L. M. Tolman), L. V. Redman, Ethel M. Terry, G. L. Wendt, Frank C. Whitmore. Cincinnati, A. B. Davis, C. P. Long, H. J. Morrison. Clearland, L. C. Drefahl, Hippolyte Gruener (subs. for W. R. Veazey), A. W. Smith, O. F. Tower. Colorado, W. D. Engle. Columbus, E. C. Hytree (subs. for Wm. L. Evans). Connecticul Valley, Joseph S. Chamberlain, C. R. Hoover. Cornell, A. W. Browne. Delaware, Charles L. Reese, Charles M. Stine. Detroit, W. P. Putnam. Indiana, Fred C. Atkinson, Horace A. Shonle (subs. for H. W. Rhodehamel). Iowa, Edward Bartow. Kansas City, H. M. Elsey (subs. for R. Hirsch), H. H. King (subs. for F. B. Dains). Lehigh Valley, John T. Little. Louisiana, C. E. Coates. Louisville, A. W. Homberger. Maryland, A. A. Backhaus, N. E. Gordon, A. E. Marshall. Midland, William J. Hale. Minnesota, Paul H. M.-P. Brinton (subs. for C. A. Mann), L. M. Henderson (subs. for R. A. Gortner). Maine, C. A. Brautlecht (subs. for A. B. Larcher). Milwaukee, T. Harry Cochrane (subs. for C. R. McKee). Nebraska, Fred W. Upson. New Haven, H. W. Foote. New York. Clarke E. Davis, Thomas B. Fress (subs. for James Kendall), F. H. Getman, Ellwood Hendrick, William Haynes, Martin H. Ittner, D. B. Keyes (subs. for B. T. Brooks), D. H. Killeffer (subs. for C. A. Browne), Sidney D. Kirkpatrick (subs. for R. G. Wright), A. C. Langmuir, K. G. MacKenzie, H. C. Parmelee, R. R. Renshaw (subs. for H. G. Sidebottom), Arthur S. Thatcher (subs. for D. W. Jayne), Arthur W. Thomas, B. R. Tunison, F. M. Turner, Jr., (subs. for H. R. Moody), David Wesson, Lois W. Woodford. North Carolina, Paul W. Gross. Northeastern, George L.

Stuart J. Bates. St. Louis, A. C. Boylston, Chas. W. Cuno. Syracuse, R. S. Fleming, Louis E. Wise, University of Illinois, B. S. Hopkins, H. C. Kremers (subs. for S. W. Parr). University of Michigan, H. H. Willard. University of Missouri, C. Robert Moulton (subs. for H. D. Hooker, Jr.). Vermont, S. Francis Howard. Virginia, W. F. Rudd, Garnett Ryland. Washington, D. C., W. D. Bigelow (subs. for R. B. Sosmanl, W. D. Collins, F. C. Cook (subs. for R. C. Wells), W. W. Skinner. Western New York, M. J. Ahern (subs. for A. M. Williamson), Walter Wallace. Wisconsin, L. F. Hawley, Victor Lenher.

On recommendation of the Advisory Committee, the Secretary was instructed to present to Edgar F. Smith, for his historical collection and future preservation, autograph letters in his possession, from prominent chemists especially such acceptances of Honorary Membership as are in the Society's files.

The following resolutions were passed on our Honorary Member, Edward Williams Morley, recently deceased, the Council remaining standing in silence for a few moments in memory of our beloved and honored colleague.

#### EDWARD WILLIAMS MORLEY

The American Chemical Society in this memorial wishes to express its appreciation of the great loss it has sustained by the death of Professor Edward W. Morley, who was to have been the Honorary

Chairman of this meeting.

Born in 1838, graduated from Williams College in 1860, he entered the Congregational ministry and was called from it to be Professor of Natural History and Chemistry in Western Reserve College in 1869. He was actively connected with this institution for 37 years and since his retirement has made his home near Hartford, Connecticut, in which city he died on February 24th of this year, shortly after

his home near Hartford, Connecticut, in which city he died of reprilary 24th of this year, shortly after his 85th birthday.

Although Western Reserve College was but little known at that time, Professor Morley soon brought it into prominence and raised himself by his own genius to be one of the foremost scientists of his time. He was as much a physicist as a chemist, and most of his published papers, curiously enough, lie in the domain of physics, although he allied himself primarily with the chemists.

With remarkable characteristics for precision and thoroughness, he possessed also an unusually clear and resourceful mind and a wonderful mechanical skill, so that he was not only a great investigator

but also an inventor of many new devices for fine and exact measurement. Among these were a prebut also an inventor of many new devices to the anti-exact measurement. Among these were a precision endiometer for the rapid determination of oxygen, two types of differential manometers, by which differences of gaseous pressure can be measured to the 1/10000 mm, of mercury, and many mechanical features of a minor sort used in the manipulation of gases. Together with Professor Michelson he developed the interferometer, an apparatus for measuring lengths in terms of the wave-length of light, and employed it in measuring the expansion of measuring lengths in terms of the wave-length of fight, and the velocity of light in a magnetic field.

The work, however, for which he is best known among chemists, is that on the densities of oxygen

and hydrogen and the ratio in which they combine, published as Smithsonian Contribution to Knowledge, No. 980. This research, finished in 1895 and on which he was engaged for eleven years, brought

him world wide recognition as a scientist of the first rank.

Professor Morley was of a very modest and retiring nature, never pushing himself forward, and for this reason he was not known intimately to many. But those few, who enjoyed the privilege of knowing him well, were impressed by the sweetness of his nature, the broadness of his culture and knowledge, the nobleness of his spirit and the wisdom of his counsel.

By making him its President in 1899 and electing him to honorary membership in 1900 this

Society honored not so much him as itself,

It was voted to grant a charter for a new local section to be known as the Erie Section with territory comprising Erie and Crawford Counties, Pennsylvania, and with headquarters at Erie.

It was voted that when the Constitutional requirements have been met the President and Secretary be authorized to issue a charter for the formation of a local section covering the counties adjacent to Rock Island and Moline, Illinois, and Davenport and Clinton, Iowa, to which waivers of jurisdiction have been received from the Iowa, the Chicago, and the University of Illinois Sections, and for which a request in Constitutional form has not vet been received.

A. M. Comey was elected successor to George D. Rosengarten on the Committee on National Policy for the ensuing two years.

A motion by C. E. Davis to reverse the action of the Advisory Committee as taken on May 13, 1922, on the Stanley Bill, was defeated.

The report of the Committee on Progress in Society Procedure was then received. After somewhat lengthy discussion, which was, unfortunately interfered with by the necessity of adjournment for the Council dinner, the whole report was referred to the Advisory Committee to consider and to report to the local sections, and to finally report at the meeting of the Society in Milwaukee.

Committees reported as follows:

Committee advisory to the Bureau of Mines and Bureau of Standards on non-ferrous metals -The committee reported a list of the subjects discussed at meetings at the Bureau of Standards on April 24 and October 31 and at the Bureau of Mines on April 25 and November 1, but mentions no definite conclusions arrived at.

Committee advisory to the War Department.—The committee reported that during the year it had discussed with the Assistant Secretary of War and officers of the War Department the question of the dyes to be used in the dyeing of uniforms and the question of a special color or mixture of colors

of the dyes to be used in the dyeing of uniforms and the question of a special color of mixture of colors to be used in uniforms which would be as invisible as possible when viewed through color screens,

**Committee in coöperation with Chemical Warfare Service,**—The committee reported close cooperation with the Chemical Warfare Service, including visits to Edgewood Arsenal and the study of 
reports submitted by the individual members of the staff.

Committee to consider question of a non-society employment Bureau.—The committee reported close canvass of the local sections with reference to the adoption of an employment service in copperation with the local sections and found very diverse sentiments. After careful consideration, they recommended to the Directors that a budget of \$2,100.00 be voted to print a maximum of four additional pages in each issue of the News Edition of Industrial and Engineering Chemistry to be devoted to employment information.

Committee on cooperation between industries and universities.—The committee reported progress

but no specific accomplishments during the year.

Committee on Endowment.—The committee reported that no funds had been added to the Society's endowment during the year.

Committee on Exchange.—The committee reported as follows:

The Society now has 434 exchanges. Of these 37 are new since our 1922 report. Fifteen exchanges have been discontinued and 5 old exchanges, previously discontinued for one reason or another, have been resumed. Ten exchange proposals to us have been refused and 3 of our requests have not been granted. Of the journals received by exchange 43 go to the office of Industrial and Engineering Chemistry, 3 to abstractors for Chemical Abstracts and the remainder to the office of Chemical Abstracts.

Exchanges are approved by the Committee only in case it is believed that the Society will benefit thereby. They save the Society a good deal of subscription money which would otherwise have to be paid out in the office of Industrial and Engineering Chemistry or in that of Chemical Abstracts. If a needed journal can be obtained more cheaply by subscription than by exchange, it is the practice to subscribe.

E. J. Crane, H. E. Howe, A. B. Lamb, Committee

Committee on Finance.—The committee reported as follows:

The Finance Committee begs to report that for the year 1922 the Society paid its own way and ended the year with a small surplus of income over expenditures. Details may be seen in the Auditors'

Report and Treasurer's Report already published.

The only changes that have taken place in the permanent investment of the funds during last year are the maturity of \$10,000 in Victory Bonds and the purchase of \$10,000 Third Liberty Bonds to

year are the maturity of \$10,000 in victory bonds and the putchase of \$10,000 kind 2000, year has been invested in Liberty Bonds. The uninvested residue of the Life Membership Fund, amounting to about \$600, has been invested in Liberty Bonds.

The various Trust Funds of the Society are in proper shape.

Attention should be called to the fact that the Life Membership Fund is not increasing. The

income from the invested fund, in fact, is not sufficient to pay the annual dues of the existing life mem-It was intended that this Fund should grow into a research fund but its growth will be exceedingly slow at the present rate.

John E. Teeple, Chairman F. J. Metzger F. G. Zinsser

Committee on Guaranteed Reagents and Standard Apparatus.—This report is printed in full in Industrial and Engineering Chemistry for May.

Committee on Importation of Foreign Books (To consider question of).—The committee reported

as follows:
Your Committee appointed to consider the question of importation of foreign books would sub-

mit the following report.

Assuming that the 'foreign books' referred to were books and periodicals sold in Germany to Americans, this is the only phase of the subject which has been studied.

Price lists have been studied, correspondence has been had with German booksellers, and a letter was addressed to Dr. F. Haber, the president of the Deutschen Chemischen Gesellschaft, copies of which were also sent to a number of booksellers and others for comment. (Copy of the letter to Dr. Haber

and his reply are appended to this report.)

It appears that during the past year the prices to Americans for German books and periodicals have been based on pre-war prices, with more or less advance; but that to nationals the prices remained the same or with slight advances until some three or four months ago, since which time they advanced very rapidly. For example, the price of the Chemisches Zentralblatt has advanced from 1000 marks in October last to 84,000 marks two weeks ago. This advance has undoubtedly been occasioned by the criticism in England and the United States. Before the German prices began to rise the cost to na-

crucism in Engiand and the United States. Before the German prices began to rise the cost to nationals was very low in terms of American money, and naturally gave rise to a multitude of complaints.

As regards the publications of the Deutschen Chemischen Gesellschaft, the letter of Dr. Haber seems to make it clear that their policy is based primarily, not on cost but upon the supposed value of the publication to the subscriber, in proportion to his means; this would seem to be rather a socialistic

standpoint.

From other sources it would appear that much of the chemical material published in Germany today is sold to nationals below the actual cost of publication, in order that the science may not suffer while to non-nationals prices are fixed on approximately the pre-war basis, augmented by the generally increased cost of all commodities. This does, of course, make up to a greater or less extent for the losses

incurred in sales to nationals.

The disparity between actual costs to nationals and non-nationals is rapidly growing less, probably owing to criticism and fear of diminishing sales to non-nationals. The present method of fixing prices appears to be somewhat as follows—first placing a Grundzahl for each publication. This seems to be a number representing the cost in marks before the war, augmented by an increase of say 50%

to 100%. This is multiplied by a Schlüssel-(key)zahl which is fixed by the Börsenverein of German booksellers, and varies with current exchange. This Schlüsselzahl seems to be about half the number of marks purchasable by a Swiss franc. These two figures multiplied together give the cost of the publication in marks, and this price will be in general somewhere about half the price quoted in dollars. If this system is fairly carried out, without rebate to nationals, no inconsiderable part of the cause of

If this system is fairly carried out, without rebate to nationals, no inconsiderable part of the cause of complaint will have been done away with.

Regarding second-hand books and files of journals, none of the restrictions of the Börsenverein apply and each dealer is free to make his own prices. Many of the quotations are made in dollars and at pre-war prices, and at these figures enormous profits must be made, but there are dealers who quote prices which are in keeping with the costs of the books to them. We can only advise against the purchase of books where the price appears too high.

Inasmuch as the Germans seem to be taking the matter of American and English criticism very with the most of the continued at least until the Fall.

seriously, we would suggest that this, or a similar committee, be continued, at least until the Fall meeting of the Society.

Respectfully submitted,

JAS. Lewis Howe, Chairman Walter Taggart R. A. GORTNER E. EMMET REID

Committee on Industrial Alcohol .- This report will be found in full in the May issue of Industrial Engineering Chemistry.

Committee on Institute for Chemo-Medical Research.—The committee reported as follows:

On behalf of the Committee on An Institute for Chemo-Medical Research I beg to say that during the year no formal meetings of the Committee have been held.

A large amount of interesting correspondence has been received covering all classes and pro-

fessions in all parts of the country, expressing deep interest in the subject covered by the Report published last year by the Chemical Foundation, and distributed to the extent of nearly a million copies. It has been particularly interesting to note how strongly the report has appealed to lawyers, a large number of whom have written words of appreciation.

number of whom have written words of appreciation.

While no funds have yet been donated which could be used for carrying out the main purpose of the Report, nevertheless it is believed that the Report has been influential in increasing cooperation between chemists, pharmacologists and biologists in the solution of problems in this important field, and it is recommended that the Committee be continued.

Respectfully submitted for the Committee,

Chas. H. Herry, Chairman

Committee on Membership.—The committee reported as follows:

Individual Members elected 1922	1, 576
Members Resigned 1922 Deceased Members 1922	
Total membership at end of year 1922	14, 400
Members dropped for delinquency January 1, 1923	1.278

W. D. BIGELOW, Chairman F. G. COTTRELL Chas. L. PARSONS

Committee on Metric System.—The committee reported as follows:

The Metric Committee reports that during the year we have published several articles in the magazines; we have procured a large number of memberships for the Metric Association; we have conducted a successful metric conference between the various scientific societies at Pittsburgh obtaining from Dr. Mendenhall an important contribution to the literature of the subject which has been published in Science; we have secured the promise of additional universities and corporations to purchase their supplies according to metric specifications; and we have carried on a considerable correspondence in regard to metric matters. EUGENE C. BINGHAM, Chairman

Committee on Nomenclature, Spelling and Pronunciation.—The committee reported as follows: Your Committee on Nomenclature, Spelling and Pronunciation respectfully submits the fol-

lowing annual report.

In the July, 1922, number of the Journal of the American Chemical Society (Proceedings, pages 77-8) the committee has published as tentative for one year a list of nomenclature rules covering the more important points concerning which there are more or less common differences in practice. These rules were worked out with the cooperation of a corresponding committee of the London Chemical Society. Criticism of them has been invited but none has been received thus far.

Copies of these rules, together with a letter urging coöperation in their application, have been sent to the editors of 49 American journals publishing chemical articles.

In view of the appointment of a number of national and international committees on nomen-

clature by the International Union of Pure and Applied Chemistry, it has seemed best for your committee, for the present at least, to leave the initiative in further nomenclature developments to these active committees, for international standards are of course better than national ones. A readiness to cooperate with the International Union committees has been expressed. Several members of your

committee (Norris, Noyes, Patterson and Crane) are on one or more of the American or International committees of the International Union.

The most important development during the past year in the field of our interest as a committee has been the working out by Dr. Austin M. Patterson of a comprehensive set of rules for numbering organic ring complexes. There is great need for reform and standardization in this domain. The rules are now being considered by the American Committee on Organic Nomenclature of the International

Union.

The chairman of your committee has received an increasingly large number of requests for information or advice on nomenclature matters. An effort has always been made to help.

E. J. Crane, Chairman

Committee on Occupational Diseases in Chemical Trades.—This report will be found in full in the May issue of Industrial & Engineering Chemistry.

Committee on Paper.—The committee reported in detail the quality of paper used in the journals of the Society and in their covers, showing the quality of the paper in the journals to be approximately the same as last year and the quality of the cover paper on the whole improved. The committee recommends that as financial conditions permit the quality of the paper should be made to consist of at least 50% of a good grade of rag and be restored to its prewar quality.

Committee on Patent and Related Legislation.-The committee reported as follows

Your Committee takes pleasure in reporting that the Sterling-Lehlbach bill, H.R. 8928, providing for the reclassification of certain governmental salaries, including those of Patent Examiners, became a law on March 4, 1923. This bill, which has received the active support of the American Chemical Society, increases the salaries of the Primary Examiners to \$5000, and provides generally for increased salaries in the scientific bureaus of the Government. So far as the Patent Office is concerned, it is our hope and expectation that this will result eventually in placing the work of that Department upon an appreciably higher plane. The passage of this bill however marks only the beginning of our endeavor.

The American patent system is based upon the proposition that the matter submitted for patenting shall be subjected, before grant of the patent, first, to an adequate examination as to its novelty; and second, to a careful review as regards the existence of a meritorious invention. Both of these and second, to a careful review as regards the existence of a meritorious invention. Both of these questions are passed upon by the patent examiners. Of the two questions, the first is essentially technical and the second essentially judicial: and therefore the competent examiner must possess a combination of qualities not to be acquired by any formal schooling. Proper examination of a patent application is a work in which long experience, an intimate acquaintance with the art, and a wide familiarity with the attitude of the Federal Courts in patent cases are required; and it is clear that these qualifications cannot exist in an xamining corps subject to a heavy turn-over in its personnel or consisting largely of young men fresh form the technical schools. Yet this is the condition which the Patent Office has encountered in ever increasing intensity during recent years, and which we hope the enactment of the new legislation will remedy, at least in a measure. But it cannot be emphasized too strongly that this legislation is only a step; that we have been facing and are still facing an actual breakdown of our examining system under the double burden of an inexperienced examining corps and an ever increasing accumulation of patents and technical literature affecting the validity of new patents; and that unless Congress can be induced to assume and maintain a liberal attitude toward our patent system its eventual collapse is inevitable.

The Patent Office divisions are now months and in some cases years behind in their examination

of applications. Every progressive manufacturer is liable to be adversely affected by this delay, which prevents the prompt commercialization of new inventions. This situation is not remedied but only aggravated by any feverish haste in the disposal of pending applications, such haste often resulting in the grant of ill-considered, inadequately searched and consequently invalid patents, which may nevertheless stand for years as obstacles in the path of real progress. It can be remedied only by the provision of a Patent Office personnel adequate to the work in hand; and for the enlightened leadership which will eventually give us such an establishment we must look to the great scientific, engineering and manufacturing associations of the country.

C. P. TOWNSEND, Chairman

Committee on Preparation and Publication of a List of Ring Systems Used in Organic Chemistry.

The committee reported progress and asked to be continued.

Committee on Revision of Melhods of Coal Sampling and Analysis (Joint with the Society for Testing Materials).—The committee reported some progress during the year in the methods of testing the fusibility of coal ash which they hope to present shortly to the Supervisory Committee of the American Chemical Society.

Committee on Standard Methods for the Examination of Water and Sewage to Coöperate with Committee of American Public Health Association.—The committee reported as follows.

As Chairman of the Committee on Standard Methods for the Examination of Water and Sewage of the American Chemical Society I wish to submit the following report:

As stated in the report of this Committee submitted March 17, 1922, the manuscript for chemical methods of water examination was completed in collaboration with the Committee of the American Public Health Association. The printing of Standard Methods is nearly completed, the entire galley proof having been corrected. When printed it is the intention of this Committee to submit a copy to the President of the Society as record of its activities to date.

A. M. Buswell, Chairman

Committee on Standardized Methods for Vitamin Research.—The committee reported progress, mendations having been received by correspondence. The committee expects to meet at the New recommendations having been received by correspondence. Haven Meeting.

Committee on Supervision of Chemical Engineering Catalog.—Did not report.
Supervisory Committee on Standard Methods of Analysis.—The committee reported as follows:
In accordance with the provisions of the constitution relating to committees of the Society,
I have to report as follows for the period that has elapsed since my last report of March 9, 1922.
The Committee on Methods of Analysis and Specifications of Commercial Soaps and Soap
Products of the Division of Industrial Chemists and Chemical Engineers submitted a report on Stand-

and Methods for the Sampling and Analysis of Commercial Soaps and Soap Products which was formally approved by the committee of which I am chairman and was printed in Journal of Industrial and Engineering Chemistry, Vol. 14, pp. 1159-63, 1922.

A report from the Committee on Fats and Oils of the Division of Industrial Chemists and Chem-

ical Engineers is now under consideration.

Respectfully submitted, W. F. Hillebrand, Chairman

The Council then adjourned.

# COUNCIL MEETING

## April 4, 1923

A second meeting of the Council was called by President Franklin on the advice of the Advisory Committee for Wednesday afternoon, April 4, 1923, at 3 o'clock. The Council was in session until half past seven, giving every Councilor full opportunity to consider the important report of the committee on Progress in Society Procedure. President Franklin was in the Chair and the following Councilors were present:

Ex-Officio.—Wilder D. Bancroft, Marston T. Bogert, Edgar B. Carter, E. J. Crane, G. J. Esselen, Jr., Charles H. Herty, W. F. Hillebrand, William Hoskins, Wm. H. Nichols, Arthur A. Noyes, H. A. Noyes, W. A. Noyes, Charles L. Parsons, Edgar F. Smith, H. W. Wiley, John Arthur Wilson, Robert E. Wilson.

Councilors-at-Large.—Roger Adams, C. L. Alsberg, A. M. Comey, H. E. Howe, Lauder W. Jones, Wm. McPherson.

Councilors-at-Large.—Roger Adams, C. L. Alsberg, A. M. Comey, H. E. Howe, Lauder W. Jones, Wm. McPherson.

Local Sections.—Akron, R. P. Dinsmore, W. J. Kelly (subs. for H. E. Simmons). Ames, W. F. Coover. Arkansas, J. W. Read (subs. for Harrison Hale). California, C. W. Porter (subs. for J. H. Hildebrand). Central Texas, J. R. Bailey. Chicago, D. K. French (subs. for W. R. Smith), L. V. Redman, Ethel M. Terry, G. L. Wendt, Frank C. Whitmore, Cincinnati, C. P. Long, H. J. Morrison. Cleveland, L. C. Drefahl, Hippolyte Gruener (subs. for W. R. Veazey), O. F. Tower. Colorado, W. D. Engle. Connecticut Valley, Joseph S. Chamberlin, C. R. Hoover. Cornell, A. W. Browne. Delaware, Charles L. Reese, Charles M. Stine. Detroit, W. P. Putnam. Indiana, Fred C. Atkinson, Horace A, Shonle (subs. for H. W. Rhodehamel). Iowa, Edward Bartow. Kansas City, H. M. Elsey (subs. for R. Hirsch). Lehigh Valley, John T. Little. Louisiana, C. E. Coates. Maryland, A. A. Backhaus, N. E. Gordon, A. E. Marshall, Minnesota, Paul H. M.-P. Brinton (subs. for C. A. Mann), L. M. Henderson (subs. for R. A. Gortner). Maine, C. A. Brautlecht (subs. for A. B. Larcher). Milwankee, T. Harry Cochrane (subs. for C. R. McKee). Nebraska, Fred W. Upson. New York, Clarke E, Davis, Thomas B. Freas (subs. for Martin H. Ittner), Sidney D. Kirkpatrick (subs. for R. G. Wright), K. G. MacKenzie, R. R. Renshaw (subs. for H. G. Sidebottom), Arthur W. Thomas, David Wesson, Lois W. Woodford. Norlheastern, J. B. Conant, George L. Coyle, George Defren, Winthrop C. Durfee, W. L. Jennings, Herman C. Lythgoe (subs. for G. S. Forbes), Robert W. Neff, J. F. Norris, L. A. Praett. Northern Indiana, J. A. Nieuwland. Oklahoma, Edwin DeBarr. Philadelphia, G. E. Barton, C. S. Brinton (subs. for H. S. Miner) J. S. Coldbaum. Edwin F. Hicks, George Defren, Winthrop C. Durfee, W. L. Jennings, Herman C. Lythgoe (subs. for G. S. Forbes), Robert W. Neff, J. F. Norris, L. A. Praet. Northern Indiana, J. A. Nieuwland. Oklahoma, Edwin DeBarr. Philadelphia, G. E. Barton, C. S. Brinton (subs. fo

A motion was first made to reconsider the reference of this report to the Advisory Committee and to place it before the meeting. It was then voted that the Council go into a committee of the whole and in committee of the whole the report was discussed. section by section, for nearly four hours. The Committee then rose and reported to the Council, the various sections of the report being acted upon as follows:

The following section was referred to the Advisory Committee with instructions to formulate a general plan of regional representation in the directorate, with the recommendation that by-laws be made to provide for reimbursement of expenses of directors incurred in attending meetings of the board other than those held at the time of general meetings, and to report at the Milwaukee meeting.

# GEOGRAPHICAL DISTRIBUTION OF DIRECTORS

The Committee believes that some form of equitable, regional representation on the Society's Board of Directors is especially to be desired, since the closer touch thus insured cannot fail to be in the interest of harmony and cooperation.

The Committee has in mind a plan of dividing the whole country into districts, six in number, each to have its own representative on the Board to be nominated and elected within the district represented. In determining boundaries for the proposed districts the Committee counsels a compromise

between a strictly membership and a strictly geographical division.

The Committee therefore recommends that the Council approve the general plan of regional representation of Directors and appoint a committee to determine territorial boundaries that will afford equitable representation, and to propose such changes in the Constitution and By-Laws as may be necessary under such a plan, its findings to be reported to the Council for final action at an early date.

In the event of the adoption of such a plan, the Committee recommends that the By-Laws be made to provide for reimbursement of the Directors for expense incurred in attending meetings of the Board.

The following section of the report was referred to the Advisory Committee to report their recommendation at the Milwaukee meeting, with the recommendation that there be three elected members of the Executive Committee and only one past-president, and that the Executive Committee be given full powers of the present Advisory Committee, and, further, that they be given the usual functions of an Executive Committee.

## THE ADVISORY COMMITTEE

The Committee originally characterized, by both name and function, as the Committee on National Policy, has become in effect since war times an Executive Committee of the Council. As such it should be continued and so employed as to increase the efficiency of the body it serves. Change of function suggests possible advantage in change of personnel. As providing more direct representation of the Council, the Committee recommends that one additional member elected from the Councolors at Large be substituted for the earlier of the two Past Presidents, that the name of the committee be changed from the Committee on National Policy to the Executive Committee of the Council. and

be changed from the Committee on National Policy to the Executive Committee of the Council, and that this committee be provided for in the By-Laws as follows:

ARTICLE XIII—3 (a). There shall be an Executive Committee of the Council consisting of the last Past President, the Editor of the Journal of the American Chemical Society, the Editor of Industrial & Engineering Chemistry, the Secretary, and three Councilors at Large, one to be elected each year for a term of three years by the Council at the annual meeting.

(b) The Executive Committee of the Council shall serve in an advisory capacity in connection with all matters of importance coming before the Council, and, when the Council is not in session, shall cooperate with the Board of Directors in handling matters which may properly come before the Council, but which in the discretion of the Directors do not call for letter ballot of the Council.

The following section was referred to the Advisory Committee, to report at the Milwaukee meeting, with the recommendation that in some way the Council be reduced in size.

#### THE COUNCIL

Closely related to the matter of making our Board of Directors a more directly representative body is that of correcting the relative inefficiency now generally admitted as characterizing our representative body, the Council. The Committee believes the Council has grown to be too large for the effective transaction of the Society's business, and, as a first step in the interest of better efficiency, favors a reduction in the number of Councilors. It is therefore recommended that the Constitution be made to provide for one representative for each two hundred members of the Society in full standing.

be made to provide for one representative for each two hundred members of the Society in full standing, or fraction thereof, instead of for each one hundred as at present, and that the Constitution be revised in accordance with this plan to read as follows:

"ARTICLE IV—Section 3. The Council shall consist of the President, the Past Presidents, the Secretary, the Treasurer, the Editors, and the Chairmen of the Divisions ex-officies, one representative elected by each Local Section for each two hundred members of the Society in full standing, or fraction thereof it may have, and twelve members elected at large, one-third of the last named being chosen each year."

The recommendation of the Committee on Progress in Society Procedure covering Article 13, Section 4, of the Constitution, regarding meetings of the Council, was laid on the table, and instead thereof the Council, on recommendation of the Advisory Committee, voted that the Monday preceding the opening of general meetings be confined to Council business and to that end no complimentary dinner to the Council be held.

It was voted that a special committee be appointed to consider the following paragraph of the report of the Committee on Progress in Society Procedure and to report at the Milwaukee meeting.

## INTERSECTIONAL MEETINGS

At Birmingham, the Council went on record as favoring Intersectional Meetings, but did not

undertake to specify the exact character of such meetings.

The Committee finds much difference of opinion among the Sections concerning the matter of whether or not Intersectional Meetings should be given the status of, and replace one of the National Society's meetings. But, while there is much difference of opinion concerning details, there plainly is a growing interest in the Intersectional Meeting as a national institution. Its merits can scarcely be

judged, however, until an attempt has been made to work out a plan in detail.

Accordingly, it is recommended that a special committee be appointed to study the subject of Intersectional Meetings in all its bearings and to formulate a working plan to be submitted to the Council for con-

sideration at its next meeting.

President Franklin appointed the following committee: M. T. Bogert, Chairman, W. Lee Lewis, R. W. Neff, O. F. Stafford, and C. E. Coates.

It was voted that the following section of the report of the Committee on Progress in Society Procedure be referred to a special committee to report at the Milwaukee meeting:

## METHOD OF ELECTION OF MEMBERS AND CLASSIFIED MEMBERSHIP

The suggestion has been made that membership would be more highly prized, as well as better safeguarded, were it required that all nominations bear the signatures of Local Section officers. This, however, is met by the objection that many prospective and desirable members have little or no contact with, and are unknown in Local Sections. The present requirement, by which the candidate must be nominated by three members of the Society in good standing, appears to the Committee to be reasonably adequate, since under its operation the Society has suffered to almost a negligible extent from undesirable members. The Committee has no recommendation to make, therefore, for further safeguarding membership under present eligibility requirements.

On the other hand, there appears to be a growing sentiment in favor of taking some step in the direction of causing membership in the Society to be more highly prized.

Those who favor some form of classification of membership insist that pride in membership would thus be enhanced and a stronger professional spirit be developed among our members. Others fear that any form of classification of members would tend to destroy the democratic spirit of the So-

All agree, however, that a strong desire to aid in the advancement of chemistry and the promotion of chemical research should impel every chemist in America to seek membership in the Society that is doing so much for the cause of chemistry. No other incentive should be needed, and yet we find even our most loyal members either criticizing or defending the present cost of membership altogether in terms of the value of the Society's publications. We learn that, of the National Engineering Societies, none has a cost of membership so low as ours, nor publications so rich and extensive. But membership in the Engineering Societies implies some degree of proficiency in engineering. Does this fact cause membership to be more highly prized so that publications are thought of as merely incidental to membership? Those who favor some form of classified membership believe it does, and ask: "May not the time have come for return to the policy of requiring that full membership in the American Chemical Society shall imply some reasonable degree of proficiency, as well as interest, in chemistry?" The question also arises: What other measures are there worth considering for their possible value in stimulating pride in membership and a stronger professional spirit in the Society?

Your Committee is prepared only to raise these questions, but, feeling that the answer is of great importance to the welfare of the Society, strongly recommends that a special committee be appointed charged with studying this whole matter of enhancing the value placed on membership and be instructed to report its findings, with specific recommendation, to the Council for final action at its next meeting.

The President appointed the following Committee: Wm. Hoskins, Chairman. A. D. Little, and Tames Kendall.

The balance of the report of the Committee, reading as follows, was unanimously adopted by the Council:

The foregoing deals with the original, and related, problems specifically named in the authorization of our Committee given by vote of the Council at Birmingham.

At Pittsburgh the Committee was further instructed to take under advisement any other matters that might be brought to its attention by the Local Sections. A considerable number of Sections responded offering criticism and comment, all of which has been given careful consideration by the Committee, which desires to make further report as follows:

#### FINANCES

A number of the Sections asked that the Committee learn the facts concerning the Society's financial condition. Feeling that all of the points raised by the Sections should be cleared up without nnancial condition. Feeling that all of the points raised by the Sections should be cleared up without delay, the Committee, at the time of its session in Washington, January 3rd and 4th last, made a request that a special report be prepared by the Secretary and published in the News Edition of Industrial & Engineering Chemistry giving a full and clear statement of the facts concerning the conduct of the Society's business. This report, which appeared on January 20th, indicates that the present financial condition of the Society is sound, and that comparison with the National Engineering Societies of the country is distinctly favorable to the American Chemical Society in both cost of membership and tangible returns for money expended.

OFFICE OF THE SECRETARY AND OF THE EDITOR OF Industrial & Engineering Chemistry

It has been suggested that there would be advantage in bringing together the office of the Secretary and the office of Industrial & Engineering Chemistry.

Inspection of these two offices by the Committee, during its recent session in Washington, showed little or no duplication of clerical work and no excess of floor space in either office. Simply bringing the two offices together under one roof, therefore, gives little or no promise of important saving

two offices together under one roof, therefore, gives little or no promise of important saving. In considering the desirability of effecting whatever saving might be brought about through bringing the two offices under one head, the Committee strongly inclines to the view of those members who contend that it would not be in the interest of good feeling in the Society to provide a plan whereby either the Secretary of the Society is charged with the conduct of only one of the Society's journals, or the Editor of one of its journals with duties affecting all of the Society's publications.

A continuance of the present arrangement is therefore recommended. In this connection the Committee wishes to suggest that, in the interest of clarity, future statements showing the cost of conducting these offices indicate a division between the cost of handling the circulation lists, which is planily a journal expense, and that of conducting the other activities of the Secretary's office; also, that the Secretary's report be made in greater detail in order that analysis of receipts and disbursements may be more readily made; and that in published statements of membership the actual paid up membership be given as well as the total membership, which, under the Constitution, includes members in arrears for two years.

# NET RETURNS FROM ADVERTISING

Much interest has centered in the question of whether or not the Society is getting proper net re-from its advertising pages. This is a problem calling for special experience and intimate knowlturns from its advertising pages. edge of the factor.

From a source believed to be authentic, the Committee has obtained the opinion that the present arrangement under which the Society for twenty-five per cent. of gross receipts is relieved of all expense in connection with its advertising, except that of printing, is an arrangement entirely favorable to the Society, yielding larger net returns than could reasonably be expected were the Society to maintain its own advertising office. It is therefore recommended that the present arrangement be continued.

# CHEMICAL NEWS SERVICE

The suggestion coming from certain quarters, that Chemical News Service be either curtailed or discontinued, the Committee believes to be ill advised. The Committee finds that the Press of the country is making good use of our Chemical News Service, and, believing that the future of chemistry in America is in no small measure beholden to the work of properly placing our science before the public, the Committee recommends a continuance of our present program.

# NEWS EDITION OF Industrial & Engineering Chemistry

As a new medium for getting chemistry to the public, in addition to providing more matter of timely personal interest for the members, the Committee heartily endorses the News Edition of Industrial & Engineering Chemistry. Since, like the journal of which it is an off-shoot, it bids fair to become selfsupporting through the advertising it carries, there would appear to be no good argument against its continuance.

#### OUR PUBLICATIONS AS A WHOLE

The Committee believes that the importance of maintaining unimpaired the Society's present unequalled publications is too evident to need defense, as is also the importance of maintaining proper

balance in our publication program between pure science and its industrial application

The Committee is inclined to look with disfavor, therefore, upon the proposal from certain quarters to reduce the cost of membership through limiting the number of journals to be received, at least unless it can be shown that this could be done without crippling the publication of research in the pure science. The Committee is informed that it costs on the average as much to put our journals on the press preparatory to printing the first copy as it does to print and distribute the whole 14,000 odd copies now distributed, while in the case of Chemical Abstracts the first cost is much greater than that for Estimates furnished the Committee show that reduction in cost of memprinting and distributing. bership through giving a choice of journals is not feasible because of the large first cost and relatively small cost of printing extra copies.

The Committee therefore recommends that there be no change in our present publication pro-

As a detail favoring constructive journal management, the Committee favors the election of the

As a detail rayoring constructive journal management, the Committee layors the election of the Editors for three year terms following the first year of probation as now provided in the election of the Secretary and of the Treasurer.

To this end it is recommended that ARTICLE IV, Section 5 (c) of the Constitution be supplemented by the provision: "If re-elected, an Editor shall be elected by the Council to serve a term of three years, beginning with the first day of January, or until his successor shall have been duly chosen."

# MORE MONEY TO LOCAL SECTIONS

From two sources comes the request that more money be used in furthering the welfare of the Local Sections. While the Committee believes that Local Sections might profitably employ larger funds for improvment of their programs and for increasing membership in the Society, it favors at least a postponement of such increase until it can be made without the use of funds needed by the Society's publications.

## THE 1923 BUDGET

The thought apparently entertained in some quarters that the Society should be able to perform its plain duty to itself and to chemistry on a much lower budget than that arranged for the current year, cannot, in the opinion of the Committee, be entertained by anyone having a knowledge of present conditions. As for some slight reduction in our budget, the Committee is unable to find any activity the sacrifice or even curtailment of which would justify the relatively small saving thus made possible. In the opinion of the Committee, the relief some are seeking must be found through increasing

the earning power of our income producing publications, and through bringing into the Society those who, though clearly eligible for membership under any reasonable qualifications, still are not supporting the cause. Reducing the cost of membership by increasing the number of those who should thus be aiding in the advancement of chemistry in America is much more worthy of American chemists than an effort to bring about such reduction through curtailment of the present program of accomplishment. Let us advance, not retreat.

That it may be clear just where it is felt that emphasis should be placed, let it be repeated that

the Committee is unanimous and emphatic in its belief that the greates immediate need of the American Chemical Society is some effective means for insuring a better pulling together on the part of its members.

Specific recommendation to this end has been made.

Furthermore, the Committee believes that some means must be found for bringing about a beller professional spirit in the Society and a greater appreciation of the value of membership.

All to the end that the American Chemical Society may work more effectively for THE ADVANCEMENT OF CHEMISTRY AND THE PROMOTION OF CHEMICAL RESEARCH.

Respectfully submitted,

A. V. H. Mory, Chairman Geo. L. Coyle L. C. Drefahl GRAHAM EDGAR J. N. SWAN

Committee on Progress in Society Procedure

H. C. Parmelee will independently discuss the Society's publications and the intimately related subject of Finances at the New Haven Meeting.

R. E. Swain has been abroad since January and it has not been possible to secure his signature to this report. However, he has expressed himself as being in harmony with the main features, as set forth in a preliminary draft placed in his hands before he left. A. V. H. M.

A Minority Report by H. C. Parmelee, covering certain sections only of the Report of the Committee on Progress in Society Procedure, was read in full and carefully considered by the Council, and it was voted that the Secretary should file the Minority Report with thanks to H. C. Parmelee for bringing his ideas to their attention.

It was voted that the Committee be discharged with the thanks of the Council for the time, thought and care they have given to the preparation of the report.

Following the report a unanimous vote of confidence carried by a rising vote was given to H. E. Howe for his conduct of Industrial and Engineering Chemistry.

A vote of thanks was then proffered to the chairmen and members of the local committees at New Haven, to the President and corporation of Yale University, to the New Haven Chamber of Commerce, to the officials of the manufacturing plants opened to the members, and to all others to whom the Society owed thanks for the generous hospitality given us at New Haven.

On recommendation of a committee of chairmen and secretaries of Divisions, it was voted first, that the Secretary of the Society be instructed to mail the final program of meetings not less than ten days before the date of the Council meeting; second, that the final date of acceptance from authors of titles of papers be set at least one month before the date of the Council meeting; third, that the Secretary be instructed to allow at least ten days between this date and the date upon which the final program must be in his hands.

President Franklin appointed the committees for April, 1923, to April, 1924, as printed on the third page of this and subsequent issues of the Journal.

The Council then adjourned.

CHARLES L. PARSONS, Secretary

Winterheimer, Louis C., Silliman Institute, Dumaguete, Philippine Islands.

Woodring, Ralph W., Bethlehem City Laboratory, 3rd & Adams Sts., Bethlehem, Pa.

Yancey, William Paul, 1625 Ripley St., Davenport, Iowa.

Young, Andrew H., 401 Campbell Ave., Schenectady, N. Y.

## CORPORATION MEMBERS ELECTED

The Ault & Wiborg Co., Cincinnati, Ohio.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

## AKRON SECTION

The second regular meeting of the Section was held on March 20, when D. P. Barnard of the Massachusetts Institute of Technology gave a talk on "The Automotive Fuel Situation."

W. J. Kelly, Secretary

# AMES SECTION

On February 25 and 26, the members of the Section attended two lectures, "Atomic Structure," and "The Periodicity of the Elements," respectively, by A. Somerfield, professor of mathematical physics at the University of Munich.

H. M. McLaughlin, Secretary

#### ARKANSAS SECTION

At a meeting of the members of the Section, held on February 28, H. E. Howe, editor of *Industrial and Engineering Chemistry*, spoke on "Chemistry and Business."

J. W. READ, Secretary

## CALIFORNIA SECTION

The 138th regular meeting of the Section occurred on April 6, at the Engineers' Club, San Francisco, Cal. Austin F. Rogers, of Stanford University, spoke on "The Structure of Matter as Revealed by X-Rays." E. D. Eastman, of the University of California, presented the subject in its relation to physical chemistry.

L. H. Duschak, Secretary

# CHICAGO SECTION

At the regular monthly meeting of the Section, held on March 23, F. B. Dains, of the University of Kansas, spoke on "Chemistry in Early Antiquity." Following is a list of subjects discussed in the group meetings, together with names of members who led the discussion in each group: "Some Chemical Theories," by W. R. Smith, of Lewis Institute; "A Few Early Methods of 'Packing-House' Chemistry," by Paul Rudnick, of Armour & Company; "The Chemist in State Control of Manufactured Foodstuffs," by T. J. Bryan, of the Calumet Baking Powder Company; "Some Chemical Reminiscences," by W. A. Converse, of the Dearborn Drug & Chemical Company; and "Chemistry for the Railroad," by G. M. Davidson, of the Chicago & Northwestern Railway.

On April 20, Ellwood Hendricks spoke before the meeting of the Section, taking as his subject "Obligations in Chemistry." The usual group meetings were held after the address of the evening.

S. L. Redman, Secretary

#### CINCINNATI SECTION

The 258th regular meeting of the Section was held on April 11, when Lauder W. Jones, of Princeton University, addressed the members, taking as his subject "Nitrogen, A Theme with Variations."

On April 23, Ellwood Hendricks addressed the meeting of the Section. His subject was "Obligations in Chemistry."

A. O. SNODDY, Secretary

#### CLEVELAND SECTION

On March 20, Edwin E. Slosson, of Washington, D. C., lectured before the meeting of the Section, his subject being "Chemistry Applied to Industry."

The local Section, in cooperation with the Cleveland Engineering Society, held a special meeting on Tuesday, April 3, when H. A. Gardner, of the Institute for Paint and Varnish Research, Washington, D. C., gave an illustrated lecture on "Research in the Paint and Varnish Industry."

At the regular meeting of the Section, held on April 23, E. C. Franklin, president of the American Chemical Society, addressed the members, his subject being "The Ammonia System of Compounds."

H. S. Booth, Secretary

## CONNECTICUT VALLEY SECTION

The Section held a joint meeting with various technical societies on April 21. After an inspection trip through the new plant of the Hartford Rubber Works, the meeting was addressed by B. J. Lemon, of that company, on the subject, "Tire Factors that Measure Vehicle Costs."

PAUL SEREX, JR., Secretary

## CORNELL SECTION

On April 18, E. C. Franklin, president of the American Chemical Society, addressed the department of chemistry of Cornell University and the members of the Section. His subject was "The Ammonia System of Compounds."

F. E. HANCE, Secretary

## DELAWARE SECTION

On April 18, H. W. Jordan, of Syracuse, N. Y., addressed the members of the Section, taking as his subject, "The Chemist as a Citizen. A Forecast of the Trend of the Times."

J. W. STILLMAN, Secretary

## DETROIT SECTION

At a joint meeting of the Associated Technical Societies of Detroit, of which the local Section is a member, held on March 19, Walter Rosenhain, director of the metallurgical department of the National Physical Laboratory of England, gave an address on the subject, "Strain and Fracture in Metals."

S. R. Wilson, Secretary

## EASTERN NEW YORK SECTION

At the regular meeting of the Section which occurred on March 23, Leon W. Parsons, of the Tide Water Oil Co., spoke on "Some Applications of Colloids to the Petroleum Industry."

At the regular monthly meeting of the Section, held on April 20, Zay Jefferies spoke on "Hardness of Metals."

E. H. Darby, Secretary

#### INDIANA SECTION

The following subjects were presented at noonday luncheons of the Section held on Tuesday of each week at Indianapolis: March 13, "The Manufacture of Beet Sugar," by Wallace Benson; March 20, "The Electronic Vibrations of Abrams," by Otto H. Gripe. At the regular meeting of the Section, held on April 13, G. H. A. Clowes, of Eli Lilly & Company, Indianapolis, Ind., spoke on the subject of "The Development of Iletin as Used in the Treatment of Diabetes." On April 21, the members of the Section were invited to Lafayette, Ind., as guests of the Purdue Section, at which time, H. C. Parmelee, editor of Chemical and Metallurgical Engineering, was the speaker.

WILLIAM HIGBURG, Secretary

#### IOWA SECTION

At a meeting of the Section, held on March 28, J. A. Hynes, of Chicago, spoke on the subject, "The Chemist in the Customs Service."

G. H. COLEMAN, Secretary

## LEHIGH VALLEY SECTION

On April 14, E. C. Franklin, president of the American Chemical Society, addressed the members of the Section, his subject being "The Ammonia System of Compounds."

R. H. BOGUE, Secretary

#### LOUISIANA SECTION

The Section, on March 21, had as its speaker, E. C. Franklin, president of the American Chemical Society, who spoke on "The Ammonia System of Compounds."

H. R. STEVENS, Secretary

#### MARYLAND SECTION

On March 29, E. C. Franklin, president of the American Chemical Society, addressed the members at the 64th meeting of the Section. Dr. Franklin's subject was "The Ammonia System of Compounds."

At the 65th regular meeting of the Section, held on April 27, W. O. Mitscherling spoke on "Cellulose Silk."

Adolph Harvitt, Secretary

# MICHIGAN AGRICULTURAL COLLEGE SECTION

At a banquet and open meeting given by the Section on March 15, J. E. Harris, of the Western Electric Co., New York City, spoke on the subject of "Putting Electrons to Work."

EDWARD ELDRIDGE, Secretary

## MILWAUKEE SECTION

At the regular monthly meeting of the Section, held on March 23, Harold C. Bradley of the University of Wisconsin addressed the Section on the subject "The Chemical Mechanism of Atrophy in the Animal Body."

ALFRED A. CHAMBERS, Secretary

## MINNESOTA SECTION

On February 19, the Minnesota Section received an invitation from the N. W. Chapter of the American Society for Steel Treating, to hold a joint dinner, followed by a lecture by Paul D. Merica, of the International Nickel Company, his subject being "Nickel and Nickel Alloys."

On April 17, Lauder W. Jones, of Princeton University, addressed the meeting of the Section. His subject was "Radicalism in Chemistry."

L. M. HENDERSON, Secretary

## NASHVILLE SECTION

The local Section had as its speaker, on March 22, E. C. Franklin, president of the American Chemical Society, who spoke on "The Ammonia System of Compounds."

H. A. WEBB, Secretary

#### NEBRASKA SECTION

The 108th meeting of the Section occurred on March 13, when S. Morgulis, of the University of Nebraska, spoke on "The Chemical Transformations in the Organism."

S. B. ARENSON, Secretary

# NEW HAVEN SECTION

The regular monthly meeting of the Section was held at Bridgeport, Conn., on March 27. The speaker of the evening was R. J. McKay, of the International Nickel Company, whose subject was "Nickel and Its Alloys."

BLAIR SAXTON, Secretary

#### NEW YORK SECTION

At a special meeting of the Section, held at Rumford Hall, Chemists' Club, on April 11, had as its speaker E. C. Franklin, president of the American Chemical Society, his subject being "The Ammonia System of Compounds."

Benjamin T. Brooks, Secretary

#### NORTHEASTERN SECTION

The 184th meeting of the Section occurred on April 9. On this occasion, E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Compounds."

E. B. Millard, Secretary

#### NORTHERN INDIANA SECTION

A regular meeting of the Section was held on March 21, when A. H. Sabin, of the National Lead Company, spoke on "Nature and Use of Paint Materials." George W. Blair, of the Mishawaka Woolen Company, discussed the "Laboratory from the Engineer's Standpoint."

On April 11, the Section held a joint meeting of the local chapter of the American Society for Steel Treating. H. M. Boylston, of the Case School of Applied Science, spoke on "Metallography." J. A. White, of the Clark Equipment Company, discussed the "Electric Furnace in the Foundry."

V. C. BIDLACK, Secretary

## NORTHERN WEST VIRGINIA SECTION

At a meeting of the Section, held on February 28, Lilly Bell Sefton Deatrick spoke to the members, taking as her subject "Analysis of Micro Amounts of Impurities in Battery Acids."

E. P. DEATRICK, Secretary

## OREGON SECTION

The 52nd meeting of the Section, held on March 31, was given over to the discussion of the subject, "New Methods of Estimating Hemoglobin, Sugar and Uric Acid in the Blood," lead by H. D. Hasins, E. E. Osgood, W. O. Holbrook and Thomas Watson.

F. L. SHINN, Secretary

# PHILADELPHIA SECTION

On April 12, E. C. Franklin, president of the American Chemical Society, addressed the meeting of the Section. His subject was "The Ammonia System of Compounds."

I. HOWARD GRAHAM, Secretary

## PITTSBURGH SECTION

The 186th regular meeting of the Section occurred on March 26, when E. C. Franklin, president of the American Chemical Society, addressed the members. His address was on "The Ammonia System of Compounds."

The 187th regular meeting was held on April 12. Prof. Giuseppe Bruni, director of research department, Pirelli & C., Milan, Italy, spoke on "Italy's Part in Chemical Scientific Development."

E S. STATELER, Secretary

#### PUGET SOUND SECTION

At a joint meeting of the Section with the Olympic Chemical Club of Tacoma, Wash., held on March 24, the members were addressed by James Kendall, of Columbia University, New York City. His subject was "Isotopes." R. W. Ellison, Secretary

#### PURDUE SECTION

The Section held a joint meeting with the Indiana Branch of the American Pharmaceutical Association on March 24. Two lectures, as follows, were given: "Use of Solutions of Inorganic Salts as Permanent Color Standards," by M. G. Mellon; and "Prosecutions Under the Shirley Amendment of the Pure Food and Drug Act," by R. E. Doolittle.

MARGUERITE G. MALLON, Secretary

## RHODE ISLAND SECTION

On April 10, E. C. Franklin, president of the American Chemical Society, addressed the members of the Section. His subject was "The Ammonia System of Compounds."

NELSON BARLOW, Secretary

#### ROCHESTER SECTION

The 151st meeting of the Section occurred on March 5, when Marston T. Bogert, of Columbia University, spoke on "Perfumes, Natural and Synthetic."

The 153rd meeting was held on March 26. At that time, Hugh S. Taylor, of Princeton University, addressed the members, his subject being "Some Problems of Catalysis."

The 154th regular meeting of the Section was addressed by E. C. Franklin, president of the American Chemical Society, on the subject, "The Ammonia System of Compounds."

ERLE M. BILLINGS, Secretary

## SACRAMENTO SECTION

At the regular meeting of the Section, on January 13, the following officers for 1923 were elected: G. H. P. Lichthardt, chairman; C. F. Hoyt, vice chairman; George E. Colby, councilor; and J. H. Norton, secretary-treasurer.

The sixth regular meeting of the Section occurred on March 17. After a short business meeting, the members enjoyed a personally conducted excursion through the Southern Pacific Railway shops, mills, laboratory, and electric steel foundry.

J. H. NORTON, Secretary

#### SAINT LOUIS SECTION

At a special meeting of the Section, on March 24, E. C. Franklin, president of the American Chemical Society, gave his lecture, entitled "The Ammonia System of Compounds."

The regular monthly meeting of the Section, held on April 12, was addressed by Lauder W. Jones, of Princeton University, who took as his subject, "Fulminates and Bi-valent Carbon."

H. A. Carlton, Secretary

#### SAVANNAH SECTION

The regular monthly meeting of the Section was held on March 8. C. B. Hicks, of Parke, Davis & Company, gave a talk on "The Standardization of Drugs."

On April 12, Herbert S. Bailey addressed the members of the Section, his subject being "Paints and Paint Pigments."

HERBERT P. STRACK, Secretary

## SOUTHEAST TEXAS SECTION

At the 21st regular meeting of the Section, held on March 7, E. C. Franklin, spoke to the members on "The Ammonia System of Compounds." P. S. Trison, Secretary

## SOUTHERN CALIFORNIA SECTION

The regular monthly meeting of the Section occurred on April 20, when Charles Galton Darwin, of the California Institute of Technology, spoke on "The Periodic System."

MARK WALKER, Secretary

## SYRACUSE SECTION

On March 23, A. W. Browne, of Cornell University, addressed the members of the Section. His subject was "Azido-Dithiocarbonate, or a Reciprocal Catalytic Pair."

On April 17, E. C. Franklin, president of the American Chemical Society, spoke to the members, his subject being "The Ammonia System of Compounds."

W. P. Hicks, Secretary

## TOLEDO SECTION

At the regular meeting of the Section, on April 17, R. J. Cowan, of the National Malleable Castings Company, spoke on "Hardness and Plastic Deformation of Metals."

GUY E. VAN SICKLE, Secretary

#### UNIVERSITY OF ILLINOIS SECTION

A series of three lectures, by Walter Rosenhain, of the British National Physical Laboratory, England, were delivered at the University of Illinois. On March 20, his first lecture, under the auspices of the local Section, was given. 'The subject was "Metallurgical Research at the National Physical Laboratory, Teddington, England." On March 21, his lecture was on "The Structure and Constitution of Alloys;" and on March 22, he spoke on "Strain, Its Relation to and Fracture of Metals."

On March 24, F. B. Dains, of the University of Kansas, spoke before the members of the Section, his subject being "Chemistry in Early Antiquity."

At a joint meeting of the local Section and the Phi Lambda Upsilon, on Friday, April 13, Lauder W. Jones, of Princeton University, spoke on "Radicalism in Chemistry."

D. T. Englis, Secretary

## VIRGINIA SECTION

The 57th meeting of the Section was held on April 13, when Graham Edgar, of the University of Virginia, gave an address on "Atomic Weights, Isotopes and the Breaking Up of Atoms."

W. G. CROCKETT, Secretary

## WASHINGTON, D. C. SECTION

The 340th regular meeting of the Section occurred on March 28, at which time E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Compounds."

The 341st regular meeting, held on April 12, had as its speaker, Carl L. Alsberg of the Food Research Institute, Stanford University, Calif., whose subject was "Agricultural and Fuel Supply as the Limiting Factors in the Food Supply of the World."

The Section held a joint meeting with the Washington Academy of Sciences and the Philosophical Society of Washington on April 17. The speakers of the evening were F. G. Donnan, professor of chemistry, University College, London, England, and James C. Irvine, principal and vice-chancellor, University of St. Andrews, Scotland, their subjects being "Membrane Equilibria," and "Composition of Starches," respectively.

J. B. Reed, Secretary

#### DECEASED

## Proceedings

## COUNCIL

MEMBERS ELECTED BETWEEN APRIL 15 AND MAY 15, 1923

Alvaro, Albert, 466 Rua Barata Ribeiro, Rio de Janeiro, Brazil.

Barnes, Garrett H., Jr., Y. M. C. A., 259 South Main St., Akron, Ohio.

Bell, J. D., Franklin, La.

Bemisderfer, Franklin Ray, 2075 E. 83rd St., Cleveland, Ohio.

Binnall, F. C., 811 Broad St., Chattanooga, Tenn.

Bowman, John R., 155 N. Dithridge St., Pittsburgh, Pa.

Briggs, Richard M., 26 Albemarle St., Rochester, N. Y.

Butts, Durain C., 60 E. Lane Ave., Columbus, Ohio.

Charpentier, E. R. H., Laboratory of Pure Science, Nela Park, Cleveland, Ohio.

Chow, H. S., 159 Austin St., Cambridge, Mass.

Colbert, James C., 419 N. Dubuque St., Iowa City, Iowa.

Cooley, Warren K., 91 Lenox Ave., Providence, R. I.

Corran, John William, 86 Upper Hill St., Princes Park, Liverpool, England.

Coughlan, W. D., 1415 Para St., Alameda, Cal.

Crabb, John Power, 27 Maryland St., Dorchester, Mass.

de Graaff, Antonius de, Library Department, Philips Glowlampworks, Eindhoven, Holland.

De Holczer, Lewis, 4101 Wellington Ave., Chicago, Ill.

Dixon, Herbert C., 800 Highland Ave., Johnstown, Pa.

Elder, Harry L., Grove City College, Grove City, Pa.

Finch, Myron W., 31 Lincoln Blvd., Kenmore, N. Y.

Follwell, Edward Harris, Box 33, Delaware, Ohio.

Foster, Sydney P., 1515 W. Monroe St., Chicago, Ill.

Freedman, L. H., 686 Washington St., Brookline, Mass.

Gaskill, E. C., 532 Columbia Ave., Palmerton, Pa.

Gilson, Richard W., 3824 S. Wisconsin St., Los Angeles, Cal.

Gordon, Samuel M., 123 Quadrangle, Iowa City, Iowa.

Hall, J. Alfred, Exchange Research Lab., San Dimas, Cal.

Harden, Wilton Cope, 9 Melvin Ave., Catonsville, Md.

* Healy, Rufus A., Harkness & Cowing Co., St. Bernard, Cincinnati, Ohio.

Hesselink, W. F., Nieuwe Kade 4, Arnhem, Netherlands.

Hirsch, Henry D., 1706 E. 56th St., Chicago, Ill.

Hoyt, Jonathan, Stauffer Chemical Co., Stege, Cal.

Isermann, Max, 4-6 Platt St., New York City.

Jasper, Joseph J., 240 Eastern Ave., S. E., Grand Rapids, Mich.

Jones, Minor C. K., Spring Gardens Plant, Con. Gas Elec. Light and Power Co., Baltimore, Md.

Kastler, Arthur O., 3125 Chestnut St., New Orleans, La.

Keans, Lee A., O'Bannon Co., West Barrington, R. I.

Ketchum, Pierce, 407 West California St., Urbana, Ill.

Kidd, William A., Hag Abdalla, Sudan, Africa.

Kunerow, Reinhold, Consumers Compressed Yeast Co., Oakland, Cal.

Leahy, James F., Hayes St., Natick, Mass.

Lehew, Donald M., 190 West 9th Ave., Columbus, Ohio.

Link, Karl Paul, Room 401, 145 Iota Court, Madison, Wis.

Mann, Matthew D., Jr., 625 Locust St., Roselle, N. J.

McComas, James A., Con. Gas. Elec. Light & Power Co., Spring Gardens Station, Baltimore, Md.

McGar, Benjamin H., Chase Metal Works, Waterbury, Conn.

McGill, Martin V., 1444 East Erie Ave., Lorain, Ohio.

Miller, Palmer, 106 S. Lake Ave., Pasadena, Cal.

Minor, Henry R., 542 Fifth Ave., New York City.

Montgomery, Wallace, 2814 Broadway St., New Orleans, La.

Parker, Henry Cole, Kent Chemical Laboratory, University of Chicago, Chicago, Ill.

Parsons, Llewellyn B., 309 E. Gorham St., Madison, Wis.

Perry, Gerald E., 145 Henry St., Brooklyn, N. Y.

Pike, Frederick A., 2351 N. Woodstock St., Philadelphia, Pa.

Powell, C. W., Jr., 445 Reber Ave., Waterloo, Iowa.

Raudenbush, Earl, Box 4188, Miami, Florida. Rice, Ambrose Clark, Grand Island College, Grand Island, Neb. Robson, Homer Louis, Dept. of Chem., Univ. of Sask., Saskatoon, Sask., Canada. Rogers, Maurice, Roxbury School, Cheshire, Conn. Ronzoni, Ethel, 6952 Clayton Road, St. Louis, Mo. Schell, Charles F., 48 Ash St., Braintree 84, Mass. Schwert, Wm. Harold, 10622 Helena Ave., Cleveland, Ohio. Sjollema, B., Biltstraat 122, Utrecht, Holland. Snyder, Carl F., Bureau of Standards, Washington, D. C. Sonnenblick, Ira, 588 Herkimer St., Brooklyn, N. Y. Stacy, Lucius E., 332 E. St., North Wilkesboro, N. Car. Stambaugh, Philip S., 117 Woodbine, Youngstown, Ohio. Stenbuck, Frederick A., New York University, New York City. Stern, Sidney M., 506 West 136th St., New York City. Story, R. G., 1440 Mulberry St., Lincoln, Neb. Stubbs, Fred G., 1346 N. H. St., Lawrence, Kans. Tharaldsen, F., Josefinegate 18, Kristiania, Norway. van der Hoeven, B. J. C., 55 Hanson Place, Brooklyn, N. Y. Van Vleet, Harley Samuel, 1308 E. Ann St., Ann Arbor, Mich. Verkade, G. E., Heimraadssingel 44, Rotterdam, Holland. Vetter, Joseph J., Howland Ave., Route No. 2, Hackensack, N. J. Wallage, Stanley T., 1429 18th St., Denver, Col. Watkins, Willard Merrill, 4805 Eastern Ave., Cincinnati, Ohio. Werkenthin, Theodore Albert, 4312 Caswell Ave., Austin, Texas. Wharton, William B., 201 Keystone Building, Pittsburgh, Pa. White, Joseph Dixon, Guilford College, N. Car. Williams, Glenn A., 573 Elms St., Akron, Ohio. Yoshioka, Susumu, Miike-Senryo-Kogyosho, Omuta Fukuokaken, Japan.

### CORPORATION MEMBER

Federal Color Laboratories, Inc., Norwood, Ohio.

## MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St. N. W., Washington, D. C.)

## CHICAGO SECTION

The annual Willard Gibbs dinner and award of medal for 1923 was held on May 25, at the City Club, Chicago, Ill. The reception and dinner was followed by the presentation of the medal by its founder, William A. Converse, and an address by the medallist, Professor Julius Stieglitz, chairman of the department of chemistry, University of Chicago, whose subject was "The Theory of Color Production in Dyes."

LEE F. SUPPLE, Secretary

## CINCINNATI SECTION

The 259th regular meeting of the Section occurred on May 16, when E. Emmet Reid, head of the department of chemistry in Johns Hopkins University, spoke on "The Influence of Sulfur on the Color of Dyes."

A. O. Snoddy, Secretary

## COLORADO SECTION

On April 25, F. C. Gilbert, of the American Smelting and Refining Co., addressed the meeting of the Section.

RUTH B. VERTREES, Secretary

## CONNECTICUT VALLEY SECTION

The regular monthly meeting of the Section was held at Middletown, Conn., May 5. A business meeting was held in the afternoon, and in the evening there was an address by W. H. Whitcomb, of the United States Rubber Co., New Haven, Conn., his

subject being "Some Applications of Chemistry to the Compounding and Vulcanization of Rubber Goods."

Paul Serex, Jr., Secretary

### CORNELL SECTION

On April 30, the following papers were presented before the meeting of the Section: "Germanium from American Zinc Blendes," by E. B. Johnson; and "The Effects of Certain Pigments on the Rate of Oxidation from Linseed Oil," by A. E. Van Wirt.

At the regular monthly meeting, held on May 14, the following program was presented: "A New Halogenoid Hydracid and Some of its Derivatives," by G. B. L. Smith; and "Vapor Pressure of Gasolines," by E. B. McConnell. F. E. Hance, Secretary

#### DELAWARE SECTION

The regular meeting of the Section occurred on May 16, when H. E. Howe, editor of Industrial and Engineering Chemistry, spoke before the members on the subject, "Some Problems of Scientific Publication."

J. W. STILLMAN, Secretary

## DETROIT SECTION

Dr. Edward C. Franklin, president of the American Chemical Society, addressed the meeting of the Section, held on April 25, his subject being "The Ammonia System of Compounds."

S. R. Wilson, Secretary

#### HAWAIIAN SECTION

On April 20, Miss C. C. Miller, of the University of Hawaii, address the meeting of the Section, her subject being "Vitamins."

RONALD Q. SMITH, Secretary

## INDIANA SECTION

On May 3, Edward C. Franklin, president of the American Chemical Society, delivered his lecture, "The Ammonia System of Compounds," before the regular meeting of the Section.

On May 11, the following programs was presented by the Section: "The Manufacture of Glue," by S. N. Wentworth, of the American Glue Company; "Garbage Disposal," by E. W. McCullough, engineer for the Garbage Disposal Plant, City Sanitary Commission; and a discussion of these subjects was lead by Paul Smith of Indianapolis.

William Higburg, Secretary

## IOWA SECTION

The regular monthly meeting of the Section occurred on April 27 and 28, in connection with the Iowa Academy of Science.

A meeting of the Section was also held on May 11, when E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Compounds."

G. H. COLEMAN, Secretary

## KANSAS CITY SECTION

The 165th meeting of the Section was held on April 28. H. E. Hancock, chemist of the Sewall Paint and Glass Co., gave an address on "New Ideas in the Manufacture of Paints and Varnishes."

On May 16, Lee E. Clark addressed the members on the subject, "Selling Yourself as a Chemist."

Left E. Clark, Secretary

## LEHIGH VALLEY SECTION

At a joint meeting of the Section and the Gayley Chemical Society of Lafayette College, Easton, Pa., held on May 11, Hugh S. Taylor, of Princeton University, gave an address on "Catalysis: Positive and Negative." R. H. Boour, Secretary

## LEXINGTON SECTION

The 87th meeting of the Section occurred on April 25, when a visit was made to the Lexington Sewage Disposal Plant and the phosphate mine at Midway, Ky.

The 88th meeting was held on May 17, when E. Emmet Reid of Johns Hopkins University, addressed the Section on "The Influence of Sulfur on the Color of Dyes."

E. L. JACKSON, Secretary

## MAINE SECTION

On May 11, F. F. Oplinger, of the University of Maine, addressed the members, his subject being "Application of the Electron Theory of Valence to Organic Chemistry."

N. E. WOLDMAN, Secretary

#### MICHIGAN AGRICULTURAL COLLEGE SECTION

At the meeting of the Section, held on April 18, Ellwood Hendrick, of New York City, spoke on "The Sense of Smell."

On April 30, E. C. Franklin, president of the American Chemical Society, addressed the members, his subject being "The Ammonia System of Compounds."

The following officers for 1923 have been elected: C. S. Robinson, chairman; Ward Giltner, vice chairman; C. D. Ball, secretary; O. B. Winter, treasurer; and D. T. Ewing, councilor.

E. F. ELDRIDGE, Secretary

#### MILWAUKEE SECTION

The regular meeting of the Section was held on April 19, when Lauder W. Jones, of Princeton University, addressed the members on the subject, "Nitrogen: A Theme with Variations."

On May 8, E. C. Franklin, president of the American Chemical Society, gave his lecture on "The Ammonia System of Compounds."

ALFRED A. CHAMBERS, Secretary

## MINNESOTA SECTION

At the meeting of the Section, held on May 16, E. C. Franklin, president of the American Chemical Society, lectured on "The Ammonia System of Compounds."

L. M. HENDERSON, Secretary

## NASHVILLE SECTION

The following papers were presented at the meeting of the Section, held on April 27: "Problems in the Manufacture of Sweet Potato Products," by J. E. Copenhaver, of the department of chemistry, Vanderbilt University; and "Progress of a Study of the Preparation of an Organic Compound by Electricity," by B. F. Armendt, of Vanderbilt University.

H. A. Webb, Secretary

## NEBRASKA SECTION

The 109th regular meeting of the Section, held on April 12, was addressed by H. P. Cady, of the department of chemistry, University of Nebraska, his subject being Radium and Radioactivity."

S. B. Arenson, Secretary

## NORTH CAROLINA SECTION

The spring meeting of the Section was held at The North Carolina College for Women, Greensboro, N. C., on May 5. The following program was presented: "Chemical Industries in North Carolina," by F. C. Vilbrandt; "The Chlorination of Juglone in hot Acetic Acid," by A. S. Wheeler and J. L. McEwen; "The Bromination of 2-Amino-p-xylene," by A. S. Wheeler and E. W. Constable; "The Schohl and Pedley Method for Determination of Calcium Compared with McCrudden's Volumetric Method," by J. O. Halverson and L. M. Dixon; "A New Ketone Reagent: p-Bromo-

phenylsemicarbazide by A. S. Wheeler and J. A. Bender; "The Constitution of the Dichlorohydroxyethylidene-bis-nitroanilines," by A. S. Wheeler and S. C. Smith; "Problems of the Chemist in the Textile Industry," by K. W. Franke; "A Vacuum Gage," by M. L. Hamlin; "A Peculiar Reaction Between Dichloroacetic Acid and Aromatic Amines," by A. S. Wheeler and S. C. Smith; "A Peculiar Phenomenon of the Bunsen Burner," by H. B. Arbuckle; "A Suggestion in Regard to Some Problems Relating to the Hydration of Ions," by E. E. Randolph.

The following offices were elected for 1923: J. O. Halverson, president; F. C. Vilbrandt, vice president; Paul W. Gross, councilor; and Leland B. Rhodes, secretary-treasurer.

Leland B. Rhodes, Secretary

#### NORTHEASTERN SECTION

The 185th meeting of the Section was held on May 11, in Boston, Mass. The following addresses were given: "The Chemical and Physical Aids to Diagnosis," by Allan Winter Rowe; and "Some Chemistry of the Insect World," by Gorham W. Harris.

E. B. MILLARD, Secretary

## OMAHA SECTION

The regular monthly meeting of the Section was held on May 1, at the plant of the American Smelting and Refining Co., with the following program: "The Omaha Plant, American Smelting and Refining Co., as an Industry," by A. E. Hall; "Chemistry as Applied to Lead Bullion Refining," by B. N. Kilbourn; "Chemistry as Applied to the Smelting of Non-ferrous Metals," by V. T. Price; "The Chemistry and Uses of Bismuth," by J. O. Betterton; and "The Laboratory and Assaying Department, Its Purpose and Relation to the Plant," by E. Wurgler.

R. N. Perkins, Secretary

## PHILADELPHIA SECTION

At the meeting of the Section, held on May 17, Edgar Fahs Smith gave a short talk on M. Carey Lea, a former prominent chemist of Philadelphia, born one hundred years ago. There was also an address by Henry Green, of the New Jersey Zinc Co., on "Structure."

J. Howard Graham, Secretary

## PITTSBURGH SECTION

At the regular monthly meeting of the Section, held on May 17, Jacob Rosenbloom, of Pittsburgh, addressed the members on the subject "The Urologist or Water Caster in Art."

E. S. STATELER, Secretary

#### PURDUE SECTION

On April 21, Ellwood Hendrick, of New York City, addressed the meeting of the Section, his subject being "The Sense of Smell."

At the meeting of the Section, on May 2, E. C. Franklin, president of the American Chemical Society, delivered his lecture on "The Ammonia System of Compounds."

The following officers have been elected by the Section for 1923: C. B. Jordan, chairman; R. E. Nelson, vice chairman; E. G. Mahin, councilor; and M. G. Mallon, secretary-treasurer.

MARGUERITE G. MALLON, Secretary

#### ROCHESTER SECTION

The 155th regular meeting of the Section occurred on May 7, when Lincoln Burrows, of the Eastman Kodak Co., gave a lecture on "Soap and Glycerine."

On May 15, the members of the Section were invited to hear a lecture by Paul D. Foote, of the United States Bureau of Standards, his subject being "The Alchemist."

The following officers for 1923 have been elected: Edward B. Leary, chairman; Lincoln Burrows, vice chairman; Erle M. Billings, secretary-treasurer; O. I. Chormann, William Webb and Charles Hutchison, executive committee.

E. M. BILLINGS, Secretary

## SAINT LOUIS SECTION

On May 7, John R. Eoff, Jr., of Garrett & Company, St. Louis, addressed the meeting of the Section. His subject was "Some Modern Conceptions of Alcoholic Fermentation."

The Section held a joint meeting with the American Society of Mechanical Engineers and American Ceramic Society on May 18. W. B. Chapman, of Chapman Engineering Co., New York City, spoke on "Fuel Saving in Modern Gas Producers and Industrial Furnaces," and Paul V. Bunn, general secretary of the St. Louis Chamber of Commerce, gave an illustrated talk on "A Trip to Cuba, Panama and Costa Rica."

H. A. CARLTON, Secretary

## SACRAMENTO SECTION

A business meeting of the Section was held on May 9. Reports of various committees were received, future programs were discussed, and important announcements were made.

J. H. Norton, Secretary

## SOUTH JERSEY SECTION

The 20th regular meeting of the Section was held on April 26, when Winfield Scott spoke on "The Acceleration of Vulcanization in Rubber," giving a history of the discovery and use of accelerators.

W. F. Twombly, Secretary

#### SYRACUSE SECTION

On April 27, the Section elected the following officers for 1923: Ross A. Baker, president; W. B. Hicks, vice president; John H. Nair, secretary; Paul S. Craig, treasurer; A. W. Kimman, councilor.

On May 7, A. F. Holleman, of Amsterdam, Netherlands, addressed the members of the Section, his subject being "Research at the University of Amsterdam."

JOHN H. NAIR, Secretary

### TOLEDO SECTION

At the regular meeting of the Section, held on May 15, O. F. Hedenburg, of the Mellon Institute, Pittsburgh, Pa., gave an address on "Chemistry as Applied to the Insecticide Industry."

Guy E. Van Sickle, Secretary

## UNIVERSITY OF ILLINOIS SECTION

An intersectional meeting of the American Chemical Society was held with the University of Illinois Section, at Urbana, Illinois, on May 4 and 5. The following program was presented:

FRIDAY, MAY 4th-2:00 P.M.

## GENERAL MEETING

Introductory-Professor W. A. Noyes.

Address: The Ammonia System of Compounds-President E. C. Franklin.

Address: The Development of our Organic Chemical Industry-Dr. L. F. Nickell.

4:00 P.M.—Athletic Games, Urbana Country Club.

6:15 p.m.-Luncheon and Social Hour.

8:30 P.M.—Short Talk, President Franklin.

Entertainment by Alpha Chi Sigma, Iota Sigma Pi and Gamma Pi Upsilon.

## SATURDAY, MAY 5th-8:00 A.M.

## GENERAL MEETING

Popular Lecture: Home Remedies—Their Claims Versus Composition—Dr. P. N. Leach.

9:30 A.M.—GROUP MEETINGS

12:00 M.-Luncheon under auspices of Chemistry Club at the "Green Tea Pot."

2:00 P.M.—Inspection of University Buildings and Grounds.

Cars will leave from the drive in front of the Chemistry Building.

## PHYSICAL AND INORGANIC GROUP

Some Reactions in the Corona Discharge and the Temperature Corresponding to Equilibrium—Gerald L. Wendt, Standard Oil Company.

Electrolytic Polarization-H. P. Cady, University of Kansas.

The Separation of the Isotopes of Chlorine, Mercury, Cadmium and Zine—W. D. Harkins, University of Chicago.

Alpha Ray Tracks in Gases—R. W. Ryan and W. D. Harkins, University of Chicago. The Accurate Measurements of the Heats of Vaporization of Liquids—J. H. Mathews, University of Wisconsin.

The Solubility of Barium Manganate and the Equilibrium Between Manganate and Permanganate—H. I. Schlesinger, University of Chicago.

Colloidal Ferric Hydroxide and Ferric Hydroxide Gel—R. E. Wilson, Standard Oil Company.

Heats of Vaporization of Metals—M. F. Fogler and W. H. Rodebush, University of Illinois.

Total and Partial Pressures of Aqueous Ammonia Solutions—T. A. Wilson and Gerhard Dietrichson, University of Illinois.

## INDUSTRIAL GROUP

## W. J. Hoskins, Presiding

Combustion of Hydrogen and Carbon Monoxide by Various Oxides—M. J. Bradley, University of Illinois.

An Improved Apparatus for Fuel Gas Analysis—F. E. Vandeveer, University of Illinois. Report of Investigation Work in Progress by the Ceramic Department; University of Illinois—C. W. Parmelee, University of Illinois.

Muriatic Tank Cars-L. F. Nickell, Monsanto Chemical Works.

The Tantalum Electrolytic Valve—E. W. Engle, Fansteel Products Company.

The Manufacturing Laboratory of the Public Health Institute—F. C. Whitmore, Northwestern University.

Laboratory Type of High Temperature Furnace for Investigation Work on Alloys—M. M. Austin, University of Illinois.

Development of Redmanol-Frank P. Brock, Redmanol Chemical Products Company.

## ORGANIC GROUP

Some Recent Studies Concerning Organo-Magnesium Halides—Henry Gilman, Iowa State College.

The Migration of Acyl from Nitrogen to Oxygen—L. Charles Raiford, State University of Iowa.

Reminiscences in the Manufacture of Phenol Plastics—Frank P. Brock, Redmanol Chemical Products Company.

Insulin-David Klein, Wilson Laboratory, Chicago, Ill.

Recent Developments in the Manufacture and Use of Furfural—Carl S. Miner, John P. Tricky and Harold J. Brownlee, Miner Laboratories, Chicago, Ill.

## EDUCATIONAL GROUP

J. H. Walton, University of Wisconsin, Presiding.

A Quantitative Analysis of Present Aims in Teaching Freshmen Chemistry—Jacob Cornog, University of Iowa.

Outline of the Essential Topics in a College Course of Elementary Chemistry—Louis A. Test, Purdue University.

The Aims and Methods of First Year College Chemistry—James H. Ransom, James Millikin University.

D. T. Englis, Secretary

## UNIVERSITY OF MICHIGAN SECTION

On April 26, E. C. Franklin, president of the American Chemical Society, addressed the members, his subject being "The Ammonia System of Compounds."

C. C. MELOCHE, Secretary

#### VIRGINIA SECTION

The 58th meeting of the Section occurred on May 11, when R. E. Loving, of the University of Richmond, addressed the members on "The Physics of the Air."

The following officers for 1923 were elected at this meeting: Wortley F. Rudd, chairman; Hall Canter, vice chairman; L. C. Bird, secretary-treasurer; Garnett Ryland and Graham Edgar, councilors.

W. G. CROCKETT, Secretary

## WASHINGTON, D. C. SECTION

The 344th meeting of the Section occurred on May 10. The Program consisted of contributions by a considerable number of members who described novel methods for analytical work, for physical measurements, or Laboratory manipulation. In a number of cases demonstrations of unusual and new forms of apparatus were made.

J. B. REED, Secretary

#### WESTERN NEW YORK SECTION

On April 21, E. C. Franklin, president of the American Chemical Society, delivered his lecture entitled "The Ammonia System of Compounds," before the members of the Section.

R. W. Hess. Secretary

## WISCONSIN SECTION

At the regular meeting of the Section, held on April 11, T. Svedberg spoke on "Recent Advances in Colloid Chemistry."

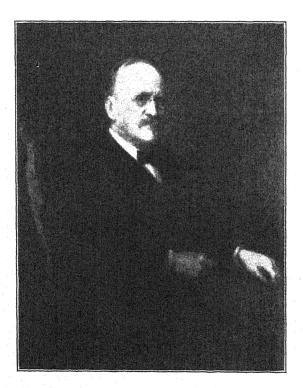

"Nitrogen: A Theme with Variations," was the subject of the address delivered by Lauder W. Jones, of the depertment of chemistry, Princeton University, on April 18, before the Section.

On May 9, E. C. Franklin, President of the American Chemical Society, gave his lecture on "The Ammonia System of Compounds," before the meeting of the members.

FARRINGTON DANIELS, Secretary

#### DECEASED

William Brady, 7642 Marquette Ave., Chicago, Ill. Died, April 26, 1923. John F. McBride, 340 South Ritter Ave., Indianapolis, Ind. Died, March 5, 1923.

Edward Williams Morley

## EDWARD WILLIAMS MORLEY

## 1838-1923

Edward Williams Morley, son of Rev. S. B. and Anna C. (Treat) Morley, was born in Newark, New Jersey, on January 29, 1838. Soon after his birth his parents moved to Hartford, Conn., where they lived until 1851, when his father was called to the pastorate of the First Congregational Church in Attleboro, Massachusetts. A severe illness in early boyhood left such effects on the young Edward that his preparatory studies were carried on with difficulty and for the most part at home under the tutelage of his father. In 1857, the family moved to Williamstown, Massachusetts, for the purpose of putting the sons, of which there were three, through Williams College, the Alma Mater of the father. Edward expected to enter the Freshman class, but the college authorities found him well qualified for the Sophomore class, in which he was duly enrolled. He graduated in 1860, and then entered Andover Theological Seminary, from which he graduated in 1864.

His health was still poor so that he did not feel able to undertake the duties of a minister, but spent the year 1864–5 in the service of the Sanitary Commission—the civil war being then in progress—in charge of their Station at Fort Monroe, Virginia. The next year he spent in study, and in 1866 read his first paper before the American Association for the Advancement of Science on "The Latitude of the Williams College Observatory." During the years 1866–1868 he was teaching in the South Berkshire Academy at Marlboro, Massachusetts. The ill health which had been troubling him for so long now having passed away, he sought and found an opportunity to preach at Twinsburg, Ohio, and almost at the same time was offered a professorship of Natural History and Chemistry in Western Reserve College at Hudson, Ohio, which he accepted. Just before taking up the duties of this new position he married Miss Isabella E. Birdsall of West Winsted, Conn., who was then residing at Hillsdale, New York.

At first Professor Morley was obliged to give instruction in most of the sciences, but his chief interest was in chemistry and he at once had a small room fitted up as a laboratory where, as one of the early catalogs states: "The class perform under the guidance of the professor all those experiments which are suitable for them, while those which demand more experience are performed for the class by the teacher." A course in quantitative analysis was also given at this early date.

Professor Morley was always an indefatigable worker. Later in life he remarked that up to the time of his first vacation in 1895 he had always considered 14 hours a fair day's work. During his first 10 years at Hudson he published 5 papers on various subjects besides doing a good deal of

¹ Proc., Am. Assoc. Adv. Sci., 1866, 384.

outside analytical work. In 1873 he also took on the Professorship of Chemistry and Toxicology in the Cleveland Medical School, which necessitated his spending considerable time going back and forth to Cleveland. This position he resigned in 1888, after he had been in Cleveland some vears. In 1878 he became interested in studying the variation of the oxygen content of the atmosphere and spent three years working on this subject. He determined the proportion of oxygen in the air from various parts of the globe or, where samples could not well be sent to him, analyses were made by chemists on the spot. In 1880 he determined the oxygen content of the air on 110 consecutive days in order to test the so-called Loomis-Morley hypothesis, according to which deficiency of oxygen was supposed to occur at times of high barometric pressure, due to downward currents bringing air from high altitudes to the surface of the earth. He summed up his results in the following words: "The theory that deficiencies in the amount of oxygen in the atmosphere are caused by the descent of air from an elevation fairly well agrees with the facts."² During the course of this work he devised and constructed a new form of precision eudiometer for the rapid determination of oxygen in air.

In 1882 Western Reserve College was moved to Cleveland and was thereafter known as Adelbert College of Western Reserve University. During this period Professor Morley served on the building committee and was one of its most active members, taking a great interest in the establishment of the college in its new quarters. As soon as he became settled in Cleveland he began the magnum opus of his life: "On the Densities of Oxygen and Hydrogen and the Ratio in which They Combine." He was occupied with this for 11 years and had it ready for publication in 1895. It appeared as "Smithsonian Contribution to Knowledge," No. 980 and was also printed in German in the Zeitschrift für physikalische Chemie, 20 (1896). This research at once gave him a world-wide reputation as a scientist of the first rank. In it one sees his remarkable insight into the fundamental nature of the problem, his great skill in devising and manipulating apparatus, his precision of measurement, and his great patience and perseverance in overcoming obstacles at times seemingly insurmountable. It is a remarkable tribute to his work that now, after nearly 30 years, the accepted values of most of the quantities, which are the averages of the best recent work in this field, are practically identical with those found by him.³

This research affords an excellent example of the thoroughness of Professor Morley's work and the care which he took to avoid unconscious bias. It consisted of three parts, each supplying an independent basis

² His principal papers on this subject are: On a Possible Cause of Variation in the Proportion of Oxygen in the Air, Am. J. Sci. [3] 18, 168 (1879), and [3] 22, 417, 429 (1881); Methods for Accurate and Rapid Analyses of Air, Am. Chem. J., 3, 275 (1881).

³ As to the density of oxygen, see the summary by Moles, quoted by the Committee on Atomic Weights for this year, This Journal, 45, 566 (1923).

for calculating the ratio by weight in which hydrogen and oxygen combine. (a) Hydrogen was weighed and then the amount of oxygen with which it combined was weighed. (b) The weight of the water formed from the weighed quantities of hydrogen and oxygen was also determined. Several sets of determinations were carried out, and the final calculations of the ratio were not made until all of them were finished. (c) The densities of hydrogen and oxygen were determined and then the ratio by volume in which these gases combine was found; then from these data were calculated the ratios by weight. These last calculations were not made, however, until after the work had been accepted for publication by the Smithsonian Institution. After that, Professor Morley went to Washington, completed the calculations, and only then learned that the third series agreed with the first two to within less than 1 part in 10,000. As he remarked in one of his papers, "The scientific conscience is rather rigorous."

Many other papers published by Professor Morley during or after this period were the results of work bearing on the research we have just been discussing as, for example, "On the amount of moisture remaining in a gas after drying with sulfuric acid," 4 "One the Amount of Moisture Remaining in a Gas after Drying with Phosphorus Pentoxide," 5 and "On the Vapor Tension of Mercury at Ordinary Temperatures."

Professor Morley had a remarkably versatile mind which embraced with equal ease any one of the physical sciences. His knowledge of mathematics and astronomy was greater than that of many devotees of those sciences, and the physicists considered him as one of their own. At the same time that he was carrying on the work on oxygen and hydrogen he was also collaborating with Professor Michelson in developing the interferometer, an instrument for measuring lengths in terms of the wave lengths of light. They used this instrument to determine the relative motion of the earth and the luminiferous ether.7 A little later, with Professor W. A. Rogers he used it for measuring the expansion of metallic bars.8 In 1904 he again took up the ether drift experiments with Professor D. C. Miller⁹ under improved conditions, but still found that the effect, if any, was much less than expected according to the Newtonian theory. This of course has brought these experiments into prominence again since the Einstein theory has appeared, and Professor Miller has been repeating them at the Mount Wilson Observatory. Previous to this he and Professor Miller had used a similar apparatus in experimenting with the velocity of light in a magnetic field. 10 They also collaborated on experiments to determine the thermal expansion of certain gases, as air, nitrogen, oxy-

gen and carbon dioxide. Unfortunately, these papers were never published, only an abstract of them appearing in the Proceedings of the American Association for the Advancement of Science.¹¹

In connection with these last experiments, Professor Morley devised a new form of differential manometer by which differences of gaseous pressure down to 0.0001 mm. of mercury could be measured. He developed another type of this manometer in collaboration with Mr. C. F. Brush, 12 with whom he also carried on a series of experiments on "The Conduction of Heat Through Water Vapor." 13

During the Hudson period, Professor Morley was sorely put to it to find ways and means to supply his needs for apparatus and books, for the college was able to purchase only what few things were indispensable for the student laboratory. He early realized the need of a good library for the proper prosecution of his research and, therefore, welcomed the opportunity of teaching in the Medical School, for that together with what outside analytical work he could do enabled him to buy the apparatus he needed and gradually accumulate a library. By the time he had finished the research on oxygen and hydrogen he possessed one of the most complete libraries of journals on pure chemistry, including full sets of the early ones in English, French and German, to be found in the United States. He also took the Journal of the Russian Physico-chemical Society for a time and learned to read Russian, so as to be able to follow the work in that country along the line of his research. After his retirement from active teaching in 1906, the college purchased this library and it is now housed in the new chemical laboratory, built in 1908-1909, for which he drew plans, and which is known as the Morley Chemical Laboratory.

Professor Morley with all of his greatness was by disposition of a most retiring and modest nature, almost too much so for his own good, as he was but little known outside the ranks of chemists and physicists. He could not bring himself to make the first move in approaching strangers, but once having formed an acquaintance he became most cordial and companionable. He enjoyed in his own quiet way the recognition and honors which came to him after the completion of his work on oxygen and hydrogen. As he expressed it to his classmates of Williams at their fiftieth anniversary, "Teaching has not absorbed all my time and strength, and I have done some pieces of scientific work which are held in good esteem, but these are mostly too technical to be described or even named here." The honors which came to him he speaks of thus: "The degree of LL.D. has been given me by three colleges, one of which was our Alma Mater (the others were Western Reserve and Lafavette, and in 1912 he received it also from the University of Pittsburgh), the degree of Ph.D. by one (Wooster), and the Doctorate of Science by Yale. I am a member of the Na-

¹⁸ Reports Brit. Assoc. Advan. Sci., 1901, p. 525.

tional Academy of Sciences, and have been President of the American Association for the Advancement of Science, and of the American Chemical Society, of which latter I am the only American honorary member. The Royal Institution of London has made me an honorary member. The Chemical Society of the same city has made me a Foreign Member, and the British Association for the Advancement of Science has made me a Corresponding Member." Besides these, under the Harrison administration he was one of the 4 members at large of the committee to receive the United States Prototype Metric Standards at the White House. 1901 he was sent to Paris as the American delegate to the General Conference on International Weights and Measures. He was awarded the following medals: the Sir Humphrey Davy Medal by the Royal Society of London in 1907, the Elliot Cresson Medal by the Franklin Institute of Philadelphia in 1912 and the Willard Gibbs Medal by the Chicago Section of the American Chemical Society in 1917. In 1912 he was Honorary President of the 8th International Congress of Applied Chemistry, and he was a member or fellow of many learned societies in this country and abroad.14 He goes on to say, "I have declined some attractive calls to other fields of work, and so my life has contained few incidents of interest."

"My health has been such as to occasion more care and solicitude than in the case of most, but I have been kept from work by illness not more than eight weeks in the forty years of my work as a teacher." He possessed remarkable vitality, however, which was a great factor in enabling him to finish successfully so many tasks; but no constitution could withstand indefinitely the strain of long hours and hard work, which he constantly imposed upon himself. In 1895 his strength gave out and he was compelled to rest. The college authorities granted him a year's leave of absence, the only one during his teaching experience, and he spent it with Mrs. Morley in recuperation and travel abroad. After his return in 1896 he was given additional assistance and in 1898 the Trustees voted to relieve him of as much teaching as he was willing to relinquish so that he could give more time to research. He chose, however, to retain the courses in general chemistry and in quantitative analysis, and he continued to teach these until he retired as Professor Emeritus in 1906.

Professor Morley had a remarkably retentive mind, so that practically everything which he read was stored in his memory, whence it could be drawn whenever needed. He not only possessed great clarity of expression in writing and speaking but, what is rarer, he had the ability to present scientific matters so that they were interesting to the layman. His public

¹⁴ The following are the societies not mentioned in the text of which he was a member: The American Academy of Arts and Sciences of Boston, American Philosophical Society, Washington Academy of Science, Astronomical and Astrophysical Society of America, German Chemical Society, French Physical Society.

lectures on such subjects as the ether-drift experiments were always well attended, and he held the interest of his audience to the very end.

Next after research he enjoyed exercising his skill on difficult chemical analyses, and during his last years in Cleveland he analyzed many complex minerals for his friend and colleague, Professor H. P. Cushing, who spent a portion of his time with the New York Geological Survey. This sort of work he continued as a pastime after he retired, and his last published paper was in collaboration with Professor Joseph P. Iddings on "Contributions to the Petrography of Java and Celebes."¹⁵

From what has been said it is seen that Professor Morley was a man of remarkable versatility. His brother says of him, "He would easily have made a great theologian. He was surpassed by none and equalled by few in his knowledge of Greek and Hebrew. He would have been eminent in mathematics, astronomy or the humanities. He had a broad knowledge and wonderful appreciation of literature and music, both of which he cultivated to the end of his life." He was a really good amateur musician. He played the chapel organ in the early days at Hudson and at Cleveland took an active interest in the musical life of the College. After he retired this versatility helped him greatly in getting the most enjoyment out of his declining years. I quote again from his letter to his classmates: "In 1906, after teaching just forty years, I retired, hoping by timely rest from hard work, to retain a fair degree of health and good spirits and power of enjoyment. I built a house and a small laboratory in West Hartford, Conn., and we are living there, seeming to find as much enjoyment as at any time in our lives." He also took a great deal of pleasure in out-of-door life, as in the growing of gladioli, using his camera and touring New England in his automobile, which he always drove himself. Only last summer he and Mrs. Morley, whose death preceded his by only a few months, took a trip into Northern Mass, and Vermont in their automobile.

Professor Morley was taken to the Hartford Hospital for an operation on January 21. Another operation was found to be necessary about three weeks later, which was not serious and from which he was expected to recover. Unexpected complications, however, set in and carried him off suddenly on February 24, just a short time after his eighty-fifth birthday. He is buried in Pittsfield, Massachusetts, where his father and mother are also buried.

He lived to a ripe old age, therefore, and it is a pleasure to know that his last years were filled with so much that was pleasant. The work of his earlier years remains as a lasting memorial of his genius. His long teaching service endeared him to several generations of students, and his colleagues and scientific friends will ever cherish his memory for his high ideals, wise counsel and unselfish service.

Wickes, Eliphalet, c/o Mr. R. H. Cory, Dana Place, Englewood, N. J.

Wochele, H. J., 11909 Saywell, Cleveland, Ohio.

Wolff, William A., 230 East 26th St., New York City.

Woodward, Gladys E., 194 Warrenton Ave., Hartford, Conn.

Yung, Chi Chao, 1110 Wertland St., Charlottesville, Va. Zergiebel, C. P., 417 Waldron St., W. Lafayette, Indiana.

#### CORPORATION MEMBER

Joseph H. Wallace & Co., Temple Court Building, New York City.

## MEETINGS OF THE SECTIONS

(Full reports of all meetings should be sent to Secretary Charles I., Parsons, 1709 G St., N. W., Washington, D. C.)

#### AMES SECTION

At the business meeting of the Section, held on June 6, the following officers were elected for the coming year: Anson Hayes, chairman; V. E. Nelson, vice chairman; R. B. Waite, secretary-treasurer; and Henry Hilman, councilor.

R. B. WAITE, Secretary

## ARKANSAS SECTION

The spring meeting of the Section was held on June 12, when Edgar F. Smith, provost emeritus, University of Pennsylvania, addressed the members.

The following officers for 1923-1924, have been elected by the Section: J. W. Johnson, chairman; G. W. Roark, Jr., vice chairman; J. W. Read, secretary; H. G. Lewis, treasurer; and Harrison Hale, councilor.

J. W. Read, Secretary

## CHICAGO SECTION

On June 14, Frank C. Whitmore, of Northwestern University, addressed the Section, his subject being "The Human Side of Mercury." The usual group meetings were held after the address of the evening.

Lee F. Supple, Secretary

## CINCINNATI SECTION

The following officers have been elected by the Section: A. P. Matthews, chairman; Thos. R. Midgely, first vice chairman; Julius Greyer, second vice chairman; Geo. K. Elliott, trustee; A. O. Snoddy, secretary-treasurer; and A. B. Davis, Martin Fischer and C. P. Long, councilors.

A. O. Snoddy, Secretary

## CLEVELAND SECTION

The second annual spring meeting of the Section was held in Cleveland on May 23, in conjunction with adjacent Sections. Various excursions to industrial plants were conducted during the day. The chief speaker at the evening meeting was H. H. Dow, president of the Dow Chemical Co., Midland, Mich., whose subject was "Business Opportunities in Japan."

H. S. Booth, Secretary

## CORNELL SECTION

The following officers for 1923-1924 have been elected by the Section: M. L. Nichols, chairman; F. R. Georgia, vice chairman; C. W. Mason, secretary-treasurer; F. H. Rhodes and G. R. Gillette, executive committee.

C. W. Mason, Secretary

### DETROIT SECTION

The Section held a joint meeting, on May 24, with the chemical and bacteriological section of the American Water Works Association, at Detroit, when the following program was presented: "The Hardness of American Municipal Water Supplies," by W. D. Collins, of the U. S. Geological Survey, Washington, D. C.; "The Physiological Effect of the Mineral Content of Drinking Water," by E. S. Chase, of Metcalf & Eddy, Boston, Mass., and H. C. Hamilton, of Parke-Davis Company; "Corrosion in Hot Water Systems," by C. R. Texter, Mellon Institute, Pittsburgh, Pa.; "The Removal of Dissolved Gases from Water," by J. R. McDermet, of the Elliot Company, Jeannette, Pa.; and "Zeolite Softening of Boiler Feed Water," by S. T. Powell, of Baltimore County Water & Electric Co., Baltimore, Md.

#### ERIE SECTION

The regular monthly meeting of the Section occurred on June 11, when H. T. Clarke, of the Eastman Kodak Company, addressed the members on the subject of "Research Organic Chemicals."

M. A. Krimmel, Secretary

#### LEHIGH VALLEY SECTION

The annual picnic of the section was held on June 2, at Saylor's Lake, Saylorsburg, Pa.

R. H. Bogue, Secretary

## LOUISIANA SECTION

On June 1, Edgar F. Smith, of the University of Pennsylvania, addressed the meeting of the Section, his subject being "Early Organic Chemistry in the United States."

At the meeting of the Section, held on June 15, Robert Glenk, curator of the State Museum, spoke on "Some Unfamiliar Resources of Louisiana."

H. R. STEVENS, Secretary

## MARYLAND SECTION

A joint meeting by the local Section with the Baltimore Section of the American Society of Mechanical Engineers was held on May 25, when E. B. Miller, of the Davison Chemical Company, spoke on "Refining and Recovery of Petroleum Oils by Silica Gel."

ADOLPH HARVITT, Secretary

#### MIDLAND SECTION

The 17th meeting of the Section occurred on March 29. H. H. Dow spoke on "Chemical Industries of the Pacific Coast and Japan," and C. H. Wagner, of the General Ceramics Company, gave an illustrated talk on "The Manufacture of Chemical Stoneware."

The 18th meeting was held on April 27, when E. C. Franklin, president of the American Chemical Society, gave his address on "The Ammonia System of Compounds."

The following officers for 1923-1924 have been elected: Ivan F. Harlow, chairman; Ross T. Sanford, vice chairman; John A. Gann, secretary-treasurer; William J. Hale, councilor; Thomas Griswold, Chester Kennedy and Paul Cottringer, directors.

JOHN A. GANN, Secretary

## NASHVILLE SECTION

At the meeting of the Section, held on May 25, Herman Schlundt, of the University of Missouri, spoke on "Energy of the Atom."

H. A. Webb, Secretary

## NEW YORK SECTION

The following program upon the general subject of "Chemistry in the Serivce of Railroading," was presented on May 4: "Some Problems Confronting the Railroad Chemist," by M. E. McDonnell, chief chemist of the Pennsylvania Railroad System; "Fire Hazards in Freight Transportation," by C. P. Beistle, chief chemist of the Bureau of Safe Transportation of Explosives; and a discussion of these papers by H. E. Smith, engineer of tests of the New York Central Lines.

At the meeting held on June 8, the program was upon the general subject of "Hafnium and Other Rare or Suspected Elements. The following papers were given: "Hafnium, its Discovery, Occurrence and Mineralogical Relations," by G. F. Kunz, president of the New York Mineralogical Club; "Undiscovered Elements," by R. B. Moore, of the Dorr Company; and "Zirconium and Some of its Complex Salts," by F. C. Nonamaker, of the Welsbach Co.

B. T. Brooks, Secretary

#### NORTHEASTERN SECTION

The 186th regular meeting of the Section occurred on June 1, at Worcester, Mass. There was an inspection of the Norton Company plant at Worcester in the afternoon, and in the evening the following papers were presented: "Characteristics of Artificial Abrasives," by L. E. Saunders; "Technical Control in the Manufacture of Grinding Wheels," by M. F. Beecher; "The Art of Grinding," by J. C. Spence; and "Electric Furnace Products as Refractory Materials," by M. R. Kirkpatrick.

E. B. MILLARD, Secretary

## OMAHA SECTION

The regular meeting of the Section was held on June 5. The subject of the evening was "The Function of the Chemist in Railroad Operation," discussed by Wm. G. Haynes and R. W. Savidge, of the Union Pacific Railroad Company.

R. N. PERKINS, Secretary

#### OREGON SECTION

On May 25, E. C. Franklin, president of the American Chemical Society, addressed the members of the Section, his subject being "The Ammonia System of Compounds."

F. L. SHINN, Secretary

### PHILADELPHIA SECTION

The annual outing of the Section occurred on June 14, at the Woodbury Country Club, Woodbury, N. J.

J. Howard Graham, Secretary

## PITTSBURGH SECTION

The annual picnic of the Section was held on June 16 at "The Pines," near Pittsburgh, Pa. Various kinds of outdoor entertainment were given.

E. S. STATELER, Secretary

#### PUGET SOUND SECTION

At the meeting of the Section, on May 24, E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Compounds."

R. W. Ellison, Secretary

#### RHODE ISLAND SECTION

On May 25, Charles James spoke to the members of the Section, his subject being "Rarer Metals, Their Preparation and Commercial Application."

The annual outing of the Section was held on June 9, at Fairbanks Farm, Greene, R. I.

NELSON BARLOW, Secretary

#### ROCHESTER SECTION

The 156th meeting of the Section occurred on May 21, when John R. Murlin, head of the department of vital economics, University of Rochester, spoke on "Recent Progress in the Extraction and Purification of Insulin."

EARLE R. BILLINGS, Secretary

## SACRAMENTO SECTION

On May 19, the members of the Section joined in an inspection of Sacremento's water filtration plant.

J. H. Norton, Secretary

#### SAINT LOUIS SECTION

At the regular monthly meeting of the Section, held on June 4, Norman C. Hill, of the Monsanto Chemical Works, gave a paper on "The manufacture of Sulfuric Acid."

H. A. CARLTON, Secretary

## SAVANNAH SECTION

On the night of March 30, George P. Shingler addressed the Section, his subject being "A New and Safe Fumigant for Fumigating Ships."

HERBERT P. STRACK, Secretary

## SOUTHERN CALIFORNIA SECTION

The regular meeting of the Section was held on May 24, with the following program: "Some Fundamental Problems in Biological Chemistry," by I. Grageroff; "The Chemical Nature of Some Physiological Products," by H. L. White; and "The Relation of Chemistry to Medicine from the Standpoint of the Bacteriologist," by M. C. Terry.

At this meeting, the following officers for the Section were elected: Walter A. Schmidt, president; W. C. Morgan, vice president; Mark Walker, secretary; C. J. Marvin, treasurer; and S. J. Bates, H. L. Payne and E. R. Miller, councilors.

MARK WALKER, Secretary

#### TOLEDO SECTION

The Section held a meeting on June 7, when G. E. Harter, of The Ransom & Randolph Company discussed the subject, "Foods that Feed and Foods that Kill."

GUY E. VAN SICKLE, Secretary

## UNIVERSITY OF MICHIGAN SECTION

On May 24, G. G. Brown addressed the members of the Section, his subject being "The Chemistry of an Automobile Engine."

C. C. Meloche, Secretary

## WESTERN NEW YORK SECTION

The last meeting of the season was held on May 29. There was a talk by W. H. Watkins, and a scientific film on the "Einstein Theory of Relativity" was shown.

R. W. HESS, Secretary

## WISCONSIN SECTION

At the 126th meeting of the Section, held on June 6, L. V. Redman, of Chicago, Ill., spoke on "The Story of Redmanol." FARRINGTON DANIELS, Secretary

DECEASED

Carl Bache-Wiig, Portland, Maine. Died, August 17, 1922. Emil Homburg, 104 West Clifton Ave., Cincinnati, Ohio. Ralph S. Potter, 29 East 21st St., New York City.

## Proceedings

## COUNCIL

President E. C. Franklin has appointed Mr. H. E. Howe the representative of the American Chemical Society on the Alcohol Trade Advisory Committee.

Past President Edgar F. Smith has been appointed to represent the American Chemical Society at the Joseph Leidy Commemorative Meeting to be held in Philadelphia on December 6, 1923.

## MEMBERS ELECTED BETWEEN JUNE 15 AND JULY 15, 1923

Arrhenius, Olaf Wilhelm, Gamla Haga, Stockholm, Sweden.

Brice, Paul B., 1431 Chesapeak Road, Camden, N. J.

Butler, George Herbert, 2 Forest Road, Bulwer Park, Durban Natal, South Africa.

Choquette, Paul J., 89 Butterfield St., Lowell, Mass.

Ehret, William F., 1732 Norman St., Evergreen, L. I., N. Y.

Erickson, Ernst, 659 Madison Ave., York, Pa.

Fujita, Eitaro, Kamichoja-Machi Senbon Nishi-iru, Kyoto, Japan.

Hall, Charles B., 2194 Ambleside Drive, Cleveland, Ohio.

Hashi, K., College of Technological Chem., Kyoto Imperial University, Kyoto, Japan.

Kao, C. H., 1324 W. Dayton St., Madison, Wis.

Kwan, Pao-Chun, Herrn Direcktor Langen Maschinenfabrick Grevenbroich, Grevenbroich, Bei Coln Niederrhein, Germany.

Lines, George O., 735 Cass St., Milwaukee, Wis.

Marzano, Rev. C., 1101 Bay St., Rosebank, S. I., N. Y.

Munning, August P., Matawan, N. J.

Newell, I. Laird, 12 Crescent St., Middletown, Conn.

Nierenstein, Maximilian, Chemistry Department, University of Bristol, Bristol, England.

Peck, Theodore A., Box 1542, St. Louis, Mo.

Potter, Truman Squire, 5515 Woodlawn Ave., Chicago, Ill.

Rager, Carroll A., 1617 Race St., Philadelphia, Pa.

Silhavy, George F., 226 Ward St., Saginaw, Michigan.

Stewart, Francis S., 418 Florence St., Palo Alto, Cal.

Stewart, James Kirby, Martinez, California.

Trossman, Henry, 606 Roosevelt Blvd., Philadelphia, Pa.

## MEETINGS OF THE SECTIONS

(Full reports of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

## INDIANA SECTION

At the regular monthly meeting of the Section, held on May 11, the following members were elected to office for the current year: H. E. Jordan, chairman; C. B. Edward, vice-chairman; H. A. Shonle, secretary-treasurer; E. W. McCullough, John R. Kuebler and Neil M. Waterbury, executive committee.

HORACE A. SHONLE, Secretary

#### PHILADELPHIA SECTION

The newly elected officers of the Section are as follows: J. Howard Graham, chairman; Elmer C. Bertolet, secretary-treasurer.

ELMER C. BERTOLET, Secretary

## RHODE ISLAND SECTION

At the annual meeting of the Section, the following officers for 1923-1924 were elected: Samuel T. Arnold, chairman; Nelson Barlow, vice-chairman; Lucius A. Bigelow, secretary-treasurer.

Lucius A. Biorlow, Secretary

#### TOLEDO SECTION

On June 7, the following officers for 1923 were elected: T. E. Moore, chairman; G. H. Anderson, vice-chairman; W. B. Holmes, councilor; and W. E. Ruth, secretary-treasurer.

W. E. Ruth, Secretary

#### WESTERN NEW YORK SECTION

At the annual meeting of the Section, the following officers for 1923 were elected: G. P. Fuller, chairman; J. A. Handy, first vice-chairman; F. L. Koethen, second vice-chairman; R. W. Hess, secretary; R. A. Nelson, treasurer; M. J. Ahern, H. N. Gilbert and J. R. MacMillan, executive committee; C. G. Derick, Walter Wallace and A. M. Williamson, councilors.

R. W. Hess, Secretary

#### DECEASED

Bowers, O. C., 2 East Reno Ave., Oklahoma City, Okla. Died, August, 1922. Bush, Donald M., 1135 Russell Ave., Bethlehem, Pa. Died, May 31, 1923. Clam, C. E., California Club, Los Angeles, Cal. Died, May 22, 1923. Cook, Frank C., Bureau of Chemistry, Washington, D. C. Died, June 11, 1923. Judge, Thos. F., Grand Falls, Newfoundland. Died, May, 1922. Katzenstein, Sidney W., Antrim Iron Co., Mancelona, Mich. Died, Dec. 29, 1922.

## NOTICE TO CANDIDATES INTENDING TO APPLY FOR A GRANT FROM THE "VAN'T HOFF FUND" FOR THE AID OF INVESTIGATORS IN THE FIELD OF PURE AND APPLIED CHEMISTRY

According to the regulations of the "Van't Hoff Fund" founded June 28, 1913, persons interested are notified that the foundation located in Amsterdam under the supervision of the Royal Academy of Sciences appropriates, from the income of the fund, annually, before March 1st, allotments to investigators in the field of pure and applied chemistry, who shall have applied for such a grant to the Committee charged with considering the applications and awarding the funds allotted.

At present this Committee is constituted as follows: A. F. Holleman, President; S. Hoogewerff, A. Smits, J. P. Wibaut, Secretary. If desirable the Committee may appoint still other members for one year only, to cooperate in judging the applications.

The names of persons to whom a grant is allowed, will be published. The grantees are requested to send to the Committee copies of papers giving the results of their work; but otherwise they are at liberty to choose the manner of publication, as well as the journal, in which to publish their results, only mentioning the fact, that the research was made with an appropriation from the "Van't Hoff Fund."

The amount available for 1924 is about fourteen hundred Dutch florins. Applications should be mailed registered to: Het bestuur der Koninklyke Akademie van Wetenschappen; bestemd voor de Commissie van het "Van't Hoff-fonds," Trippenhuis, Kloveniersburgwal, te Amsterdam, with a detailed account of the proposed use of the grant, the amount required, and the reasons upon which the candidates ground their claim. They must be received before November 1, 1923.

A. F. HOLLEMAN, President, J. P. Wibaut, Secretary

Amsterdam, the month of June, 1923

# Proceedings

## GENERAL MEETING MINUTES

The Sixty-Sixth General Meeting of the American Chemical Society was held in the Auditorium, Milwaukee, Wisconsin, Monday, September 10, to Friday, September 14, 1923.

Opening addresses were given by Clare H. Hall, Chairman of the Milwaukee Section of the American Chemical Society; Hon. Daniel W. Hoan, Mayor of Milwaukee; Hon. Emmanuel Philipp, President Milwaukee Association of Commerce; and Rev. Albert C. Fox, President Marquette University. Dr. E. C. Franklin responded on behalf of the Society.

Two general addresses were the feature of the Tuesday morning session as follows: Charles F. Burgess, Director, Burgess Laboratories. "Marketing Chemical Discoveries."

Arthur I. Kendall, Dean of the Medical School, Northwestern University. "Bacteria and the Chemist."

The previous custom of having general addresses in the afternoon session was abandoned and instead thereof three special meetings of the more fundamental divisions of Physical and Inorganic Chemistry, Organic Chemistry, and Chemical Education were held with papers especially selected to meet the needs of all chemists present.

On Tuesday evening a complimentary dinner and entertainment was given to the members and guests by the Milwaukee Section. Approximately one thousand sat down to this dinner. The program consisted of songs, dancing, and instrumental music.

On Wednesday at 8 P. M., a reception was held at the Marquette University gymnasium followed by public addresses by Mrs. Thomas G. Winter, President General Federation of Women's Clubs, and the annual address of the President of the Society. President Franklin took as his subject, "Systems of Acids, Bases and Salts." Past President Edgar F. Smith presented the Priestley Medal in absentia to Professor Ira Remsen.

On Thursday evening group dinners and college reunions were held and the members also attended a very interesting and lively amateur boxing contest at the Milwaukee Athletic Club.

A special program consisting of dinners, automobile drives, etc., was arranged for the ladies and a complimentary dinner was given to the wives of the Councilors on Monday evening.

Wednesday and Thursday were otherwise given up wholly to divisional meetings.

The following Divisions and Sections met: Divisions of Agricultural and Food Chemistry, Biological Chemistry, Cellulose Chemistry, Dye Chemistry, Fertilizer Chemistry, Industrial and Engineering Chemistry, Leather Chemistry, Chemistry of Medicinal Products, Organic Chemistry, Petroleum Chemistry, Physical and Inorganic Chemistry, Rubber Chemistry, Sugar Chemistry, Water, Sewage and Sanitation; Sections of Chemical Education, Gas and Fuel Chemistry, and History of Chemistry.

The divisions elected officers as follows:

Division of Agricultural and Food Chemistry: Chairman, C. H. Bailey; Vice-Chairman, E. F. Kohman; Secretary, C. S. Brinton; Executive Committee, G. E. Holm, J. W. Read, R. H. Carr.

Division of Biological Chemistry: Chairman, W. T. Bovie; Secretary, R. A. Dutcher.

DIVISION OF CELLULOSE CHEMISTRY: Chairman, G. J. Esselen, Jr.; Vice-Chairman,

- Louis E. Wise; Secretary-Treasurer, L. F. Hawley; Executive Committee, The Officers ex-officio and Harold Hibbert, A. W. Schorger.
- Division of Due Chemistry: Chairman, W. J. Hale; Vice-Chairman, R. E. Rose; Secretary, R. Norris Shreve; Executive Committee, L. A. Olney, L. F. Johnson.
- Division of Fertilizer Chemistry: Chairman, F. B. Carpenter; Vice-Chairman, R. N. Brackett; Secretary, H. C. Moore; Executive Committee, H. J. Wheeler, C. H. Jones, E. W. Magruder, and A. J. Patten.
- Division of Industrial and Engineering Chemistry: Chairman, D. R. Sperry; Vice-Chairman, W. A. Peters; Secretary, E. M. Billings; Executive Committee, W. K. Lewis, C. E. Davis, E. R. Weidlein, C. S. Miner, C. E. Coates.
- Division of Leather and Gelatin Chemistry: Chairman, John Arthur Wilson; Vice-Chairman, F. P. Veitch; Secretary, Arthur W. Thomas; Executive Committee, I. D. Clarke, L. M. Tolman.
- Division of Chemistry of Medicinal Products: Chairman, E. H. Volwiler; Secretary, H. A. Shonle; Executive Committee, E. B. Carter, Frank O. Taylor.
- DIVISION OF ORGANIC CHEMISTRY: Chairman, R. R. Renshaw; Secretary, J. A. Nieuwland.
- DIVISION OF PETROLEUM CHEMISTRY: Chairman, R. R. Matthews; Vice-Chairman, R. E. Wilson; Secretary, W. A. Gruse; Executive Committee, E. W. Dean, W. F. Faragher.
- Division of Physical and Inorganic Chemistry: Chairman, Graham Edgar; Vice-Chairman, Arthur Hill; Secretary, H. B. Weiser; Executive Committee, R. E. Wilson, G. S. Forbes, A. W. Browne, C. E. Coates, H. Schmidt.
- DIVISION OF RUBBER CHEMISTRY: Chairman, E. B. Spear; Vice-Chairman, C. R. Boggs; Secretary, A. H. Smith; Executive Committee, Winfield Scott, W. B. Wiegand, Ira Williams, L. B. Sebrell, H. B. Pushee.
- DIVISION OF SUGAR CHEMISTRY: Chairman, F. W. Zerban; Vice-Chairman, H. W. Dahlberg; Secretary-Treasurer, Frederick Bates; Executive Committee, C. E. Coates, W. B. Newkirk, J. S. Osborne, H. Z. E. Perkins, M. J. Proffitt, J. R. Withrow.
- Division of Water, Sewage & Sanitation Chemistry: Chairman, W. W. Skinner; Vice-Chairman, F. W. Mohlman; Secretary, F. R. Georgia; Executive Committee, A. L. Fales, A. M. Buswell.

## DIRECTORS' MINUTES

The Directors of the American Chemical Society met in the President's Room at the Hotel Pfister, Milwaukee, Wisconsin, on the evening of September 10, 1923, at 10:30 p. m., following the Council Meeting, with President Franklin in the Chair and Directors W. D. Bancroft, George D. Rosengarten, H. P. Talbot, John E. Teeple, W. R. Whitney, and Charles L. Parsons present.

The rebate to local sections recommended by the Council and appearing in the Council Minutes was approved by the Directors, with the additional proviso that the payments be made to local sections, on rebates received from the dues of New members obtained through them, on a quarterly basis; *i. e.*, on March 1, June 1, September 1, and December 1.

It was moved to approve the rate of \$6.41 per page for composition, make-up, lock-up, and make-ready arrangement by the editor of Chemical Abstracts with the Eschenbach Printing Company for the use of six point type on a seven-point base in the index.

It was voted to make an appropriation to the editor of Chemical Abstracts not exceeding \$975.00 covering the purchase of a safe cabinet for protecting his collective index from fire and for the purchase of a new typewriter for his office.

The Treasurer reported the following transactions since the last Directors' Meeting:

April 23, 1923	Sold \$1000 Brooklyn Rapid Transit 7% Unstamped certifi-	
	cates at 92°/4, General Investments	\$ 926.00
April 23, 1923	Sold \$5000 Brooklyn Rapid Transit 7% Unstamped certifi-	
	cates at 925/8, Morris Loeb Fund	\$4623.75
May 20, 1923	Sold (at maturity) \$20,000 Victory Liberty Loan Bonds, ac-	
	count Temporary Investments.	
May 20, 1923	Sold (at maturity) \$100 Victory Liberty Loan Bond, Priest-	
	ley Memorial Fund.	
June 26, 1923	Called and paid to-day, \$200.00 Federal Land Bank of Hous-	
	ton, 5% 1938 Bonds. Priestley Memorial Fund.	
*,		

It was voted that the Treasurer be authorized to pay from the Priestley Memorial Fund for procuring the Priestley Gold Medal of 1923.

The meeting then adjourned.

CHARLES L. PARSONS, Secretary

## ADVISORY COMMITTEE MINUTES

The Advisory Committee of the American Chemical Society met in the President's room at the Hotel Pfister, Milwaukee, Wisconsin, at 10:00 a. m., Monday, September 10, with President Franklin in the chair and Messrs. Edgar F. Smith, A. M. Comey, H. E. Howe, A. B. Lamb, and C. L. Parsons present.

The Secretary was instructed to proceed along the lines already under way to obtain a coöperative committee between the American Chemical Society, the American Medical Association, and the Society of Bacteriologists and Pathologists with reference to joint action covering the interests of physicians, chemists, bacteriologists, and pathologists in legislation now being presented in certain states. The President was authorized to appoint members from the American Chemical Society to sit on such joint committee, provided the other societies agreed.

It was voted to recommend a rebate to local sections on new members obtained through local sections as outlined in the Council Minutes.

A request having been received from H. W. Gillett for the approval of the Advisory Committee looking toward the use of oxygen in metallurgical processes, the Advisory Committee, after considering the report offered, gave its approval thereto.

It was voted that owing to the inability of the Society to take part actively in the final determination of the candidate for the Perkin Medal, it was inadvisable to make nominations therefor.

A request having been received from the Chairman of the International Critical Tables for the appointment of a successor to Dr. C. E. K. Mees, who had resigned from the editorial board, the President, with the approval of the Advisory Committee, appointed S. C. Lind thereto.

The committee then adjourned.

CHARLES L. PARSONS, Secretary

## EXECUTIVE COMMITTEE MINUTES

The Executive Committee met in the Directors Room of the Auditorium at Milwaukee, Wisconsin, at 2:30 p.m., Tuesday, September 11, 1923, with the following members present: E. C. Franklin, E. J. Crane, J. E. Teeple, George D. Rosengarten, H. E. Howe, and C. L. Parsons.

The rules presented by the Supervisory Committee on Methods of Analysis and referred by the Council to the Executive Committee with power were unanimously approved. The rules can be found printed in the Council Proceedings.

Dr. Wilder D. Bancroft having reported that the Chemical Society has voted in England that papers submitted at any meeting can be published either in the Transactions of the Chemical Society or the Journal of Physical Chemistry, as the author prefers, the Secretary was instructed to modify the announcement sent out on the preliminary and final program regarding Society ownership of papers to read as follows:

All papers presented before the General Meeting, Divisional Meetings, or meetings of local sections are the property of the American Chemical Society unless released by the Society's Editors or by the Editor of the Journal of Physical Chemistry. No paper already offered for publication in another journal should be read. If release is desired, address the editor of the appropriate journal; i. e., H. E. Howe, A. B. Lamb, or W. D. Bancroft.

The committee then adjourned.

CHARLES L. PARSONS, Secretary

## COUNCIL MINUTES

The Council of the American Chemical Society met in the Red Room of the Hotel Pfister, Milwaukee, at 2:30 p. m., Monday, September 10, the meeting continuing, with a short intermission for dinner, until 10:30 p. m. President Franklin was in the Chair and the following Councilors were present:

Ex-Officio.—Wilder D. Bancroft, A. M. Buswell, F. B. Carpenter, Edgar B. Carter, E. J. Crane, G. J. Esselen, Jr., Charles H. Herty, W. F. Hillebrand, J. S. Hughes, Arthur B. Lamb, Ralph R. Matthews, H. A. Noyes, Charles L. Parsons, George D. Rosengarten, Edgar F. Smith, D. R. Sperry, H. P. Talbot, John E. Teeple, W. R. Whitney, John Arthur Wilson, Robert E. Wilson.

Councilors-at-Large.—Roger Adams, A. M. Comey, W. D. Harkins, H. E. Howe, W. Lee Lewis, R. H. McKee.

Local Sections .- Akron, C. W. Bedford (subs. for H. E. Simmons), R. P. Dinsmore. Ames, F. E. Brown (subs. for Henry Gilman). Arkansas, Harrison Hale. Chicago, Herbert N. McCoy, L. V. Redman, W. R. H. E. Howe, Chairman of the Committee on Garvan Chemical Prizes for secondary schools, outlined the gift of Mr. and Mrs. Francis P. Garvan and the preliminary work and future plans of the Committee as follows:

Shortly after the spring meeting President Franklin appointed a committee consisting of W. D. Bancroft, Charles H. Herty, H. E. Howe, Chairman, and A. H. Williams, Secretary, to organize the work incident to a prize essay contest, made possible by a gift from Mr. and Mrs. F. P. Garvan, as announced in the following letter.

June 1, 1923

"Council of the American Chemical Society Gentlemen:

In order that the youth of our country may have an intelligent appreciation of the vital relation of the development of chemistry to our national defense, to the intensification and purification of industry and agriculture and to the progress of medicine through the "Age of Chemistry" upon which we have entered, and in memory of our daughter, Patricia, Mrs. Garvan and myself tender to you the sum of ten thousand dollars. Six thousand dollars is to be expended by you in awarding in each State six prizes of twenty dollars in gold to the students in all secondary schools, public and private, for the six best essays evidencing an understanding of the importance of chemistry in our national life. The remaining four thousand dollars is to defray the expenses of the contest.

In addition, we have provided for six four-year scholarships in chemistry, or chemical engineering at Yale University or Vassar College, to be awarded by you among the successful contestants in each of the several States. These scholarships will carry five hundred dollars a year and tuition. The choice of subjects, all rules and regulations governing the contests, the awarding of the prizes, and scholarships, et cetera, are to be under your absolute control and direction.

Sincerely yours, Francis P. Garvan"

Upon vote of the Council this gift has been accepted and the following letter of acceptance forwarded by President Franklin.

"August 21, 1923

Mr. Francis P. Garvan 67 Wall Street New York City Dear Mr. Garvan:

On behalf of the American Chemical Society and upon the authorization of its Council it gives me great pleasure to accept the gift of Mrs. Garvan and yourself in memory of your daughter Patricia.

Your plan by which a more extensive interest in chemistry will be engendered has the enthusiastic approval of the Society. I have, therefore, appointed a committee composed of H. E. Howe, Chairman, W. D. Bancroft, Charles H. Herty and Alexander Williams, Jr. (Secretary) to organize and carry forward this work.

Believe me, Sir,

Very sincerely yours, E. C. Franklin, President"

In carrying out the details of the contest the committee has approved and is about to issue a poster announcing the prize contest, this poster to be sent to all secondary schools, both public and private, libraries and other places where its posting will forward the contest. Means have also been provided whereby 10,000 sets of books of five volumes each will be sent gratis to the accredited secondary schools of the country and a large number of sets deposited in libraries, selected with the cooperation of the American Library Association.

Preliminary steps have been taken toward the formation of state committees which will award the prizes in the individual states and a national committee will be formed to award the Scholarships at Yale and Vassar.

A publicity campaign has been formulated and it will soon be time to call upon the various members and local sections of the American Chemical Society to carry forward the very considerable amount of detailed work incident to the successful completion of the project. The committee has reason to believe that a demonstration that this contest can be highly successful and the interest of a large number of boys and girls secured may lead to still greater things for chemistry in this country. It wishes to emphasize that the task in hand is one for which the Society as a whole has a large measure of responsibility and that the committee cannot hope to properly discharge its duties without a large amount of effort being given to the contest by all members of the Society.

A booklet has been prepared which, with the posters, will shortly be sent to high and secondary school principals and professors of chemistry giving details of the contest and the committee urges everyone to be prepared to render such assistance as may be required by perspective contestants.

It was voted to adopt the report and to instruct the Secretary to express the Society's hearty thanks and appreciation to Mr. and Mrs. Garvan for their splendid gift.

Edgar F. Smith presented a report of his conference with the officials of the Allied Chemical and Dye Corporation regarding the \$25,000 prize announced in Proceedings for 1922, page 88.

The following vote was prepared and spread on the minutes and the Secretary was instructed to forward a copy of the same to the Allied Chemical and Dye Corporation:

The American Chemical Society received at its last annual meeting the announcement of a monumental gift for the promotion of chemistry in America—an annual prize of \$25,000, founded by the Allied Chemical and Dye Corporation. The Council reaffirms its acceptance of this gift with deep appreciation of its importance.

The committee to whom this matter was referred having agreed that the name of the prize shall be

## The American Chemical Prize (Founded by the Allied Chemical and Dye Corporation)

the Council heartily concurs in this recommendation. The committee also recommends that the jury of award be a self-perpetuating body consisting of seven members, five of whom shall represent the American Chemical Society and two shall be named by the Allied Chemical and Dye Corporation. This the Council also approves and empowers its committee composed of Edgar F. Smith, Charles F. Chandler, Ira Remsen, Frank P. Venable, and Theodore W. Richards to select the initial five members representing the American Chemical Society.

The Council further approves the following supplemental recommendations of the committee:

The prize shall be awarded annually to that chemist, man or woman, a citizen or a resident of the United States of America at the time, who in a certain year or through a period of years has made a contribution of high merit or in some marked way has promoted the betterment of society through the science of chemistry.

Chemists engaged in any division of their science including the teaching of chemistry shall be cligible for the prize.

The jury of award shall select the recipient of the prize. It shall formulate the rules and regulations governing the award of a prize.

The prize shall be presented at an annual meeting of the American Chemical Society. The recipient of the prize will be expected to receive the prize in person and shall be invited to deliver an address before the Society, his expenses in attendance at the meeting to be defrayed by the Allied Chemical and Dye Corporation.

It was voted to authorize the Section of Chemical Education to form a Division of Chemical Education.

The following new fellowships and continuation of annually awarded fellowships were announced:

The Hammermill Paper Company has given a fellowship of \$1200 to the New York State College of Forestry, to be known as the "Hammermill Fellowship in Pulp and Paper Manufacturing."

The Grasselli Chemical Company has renewed its fellowship for \$750 and scholarship for \$500 in the Massachusetts Institute of Technology.

The du Pont Company has also renewed its fellowship in the Massachusetts Institute of Technology.

The Public Health Institute of Chicago has renewed its twelve \$500 research fellowships in chemistry at Northwestern University, and in order to preserve the time of the fellows for research, the same Institute has made an additional annual appropriation of \$3000 for the support of a special laboratory for the preparation of research intermediates not available on the market.

The National Lime Association has awarded a \$1000 fellowship at the Massachusetts Institute of Technology.

The du Ponts, the National Lime Association, and the Grasselli Chemical Company have renewed their fellowships at the Ohio State University.

A. F. Gallun and Sons have renewed their annual grant of \$5000 for leather chemistry research to Arthur W. Thomas at Columbia University.

The du Pont Company has provided a research fund of \$3600 for research in plasticity at Lafayette College for 1923-24.

The Palm Olive fellowship of \$2000 on the detergent action of soap has been awarded to Paul H. Fall, who will work under Dr. Bancroft at Cornell University.

The Fleischmann Company has renewed its fellowship at the University of Minnesota.

The Stretmann Biscuit Company, of Cincinnati, Ohio, has given a fellowship of

\$1000 to the University of Minnesota for the study of the chemistry involved in the cracker manufacture.

The following resolution presented by Professor E. C. Bingham, Chairman of the Metric System Committee, was adopted:

All articles relating to laboratory tests of procedure published in any of the journals of the American Chemical Society shall contain dimensions expressed metrically. Other equivalents may be added where the author so desires.

The following report of the Editor of Technologic Monographs was read and accepted:

To the President of the American Chemical Society:

During the present year we have been more successful in arranging for the preparation of new monographs than for the delivery of manuscripts, some of which are long overdue.

Three monographs of this series have been published during the year—Glue and Gelatin by Alexander, The Chemistry of Leather Manufacture by Wilson, and Wood Distillation by Hawley. These volumes have been widely and for the most part favorably reviewed.

The manuscript on Coal Carbonization by Porter is expected the last of the year. Corrosion of Alloys by Fink is not yet ready for our reviewers, and the necessity of Braham's going to Europe has delayed work upon his monograph on Cyanamide. Shale Oil by McKee is being revised by the author. Saklatwalla expects to finish his work on Aluminothermic Reduction of Metals at an early date. Waggaman's monograph being prepared without contract, on Phosphoric Acid, Phosphates, and Phosphatic Fertilizers, will be in our hands October 15. G. A. Burrell's manuscript on Extraction of Gasoline from Natural Gas will be ready late this autumn.

During the year contracts have been made for the following monographs: Physical and Chemical Properties of Glass by George W. Morey, due October 1, 1924; Chemistry of the Treatment of Water and Sewage by A. M. Buswell, due September 1, 1924; Chemistry of Wheat Flour by C. H. Bailey, due July 1, 1924; Rare Gases of the Atmosphere by R. B. Moore, due August 1, 1924; Manufacture of Sulfuric Acid by Andrew M. Fairlie, due January 1, 1925; Soluble Silicates by J. G. Vail, due April 1, 1925; Equilibrium between Soluble Salts and their Aqueous Solutions by W. C. Blasdale; Protective Metallic Coatings by H. S. Rawdon, due January 1, 1926. There will be prepared by J. E. Teeple a monograph dealing with the Searles Lake project from a research and chemical engineering viewpoint, but the excitate and title have not yet been chosen. C. R. Hoover will also prepare a monograph on the Materials of Laboratory Construction.

This year the terms of Messrs. C. P. Townsend and C. G. Derick as members of the Board expire and the editor desires to nominate F. C. Zeisberg and W. A. Schmidt as their successors.

Respectfully submitted, H. E. Howe, Editor

The Council elected F. C. Zeisberg and W. A. Schmidt as members of the Board, as recommended.

The following ad interim report of the Finance Committee was accepted:

## INTERIM REPORT OF THE FINANCE COMMITTEE

The budget for 1923 as approved by the Directors anticipated receipts of \$308,400 and expenses of \$311,800. As no one can probably foresee the receipts or expenditures of the Society to an accuracy closer than 1%, this was considered a balanced budget.

At the present time it looks as though the receipts from advertising will be about \$16,000 less than our estimate, and receipts from other sources will be approximately \$9000 more than our estimate giving net receipts for the year of probably \$302,000.

It looks as though expenses for the year will be about \$302,000 or \$303,000, due to various savings in a number of different departments. If these savings all materialize, then, we should expect to have the receipts and expenditures balance within at least \$2000 or \$3000.

The net advertising receipts will be very nearly the same as they were last year. The plans for this year, however, called for a very considerable increase in advertising receipts, and these did not materialize due to changed business conditions.

F. J. METZGER
F. G. ZINSSER
JOHN E. TEEPLE, Chairman

The invitation to hold the Spring Meeting of 1924 in Washington, D. C., was accepted.

The invitation to hold the Fall Meeting of 1924 in Ithaca, N. Y., was accepted.

It was voted that the Council recommend to the Directors that local sections be allowed a rebate of \$5.00 on each new member of the Society and \$2.50 on any former member reinstated in membership, obtained by them and transmitted to the Secretary of the Society by the Secretary of the local section or chairman of their membership committee. It was further recommended that if this vote was approved by the Directors the following rules shall govern:

- 1. Rebates shall apply only on the first payment of new members paying full \$15.00 dues.
- 2. Rebates shall be claimed at time of transmittal of application and shall apply only to applications transmitted to or by the secretary of the local section or the chairman of their membership committee.
- 3. Rebates shall not apply to members resigning in good standing who are reinstated until after a period of two years has elapsed following their resignation.

This motion was approved by the Directors on the following day with the addition of a fourth requirement, namely:

4. Payments of these rebates to local sections shall be made quarterly, on March 1st, June 1st, September 1st, and December 1st.

The Committee on Intersectional Meetings reported progress and was continued until the next meeting.

The Committee on Classified Membership reported progress and was continued until the next meeting.

It was voted to establish a local section with headquarters at State College, Pennsylvania, comprising the counties of Center, Clearfield, Clinton, Union, Mifflin, Huntingdon, Lycoming, and Blair, as soon as the requirements have been met by the chemists petitioning.

On request of the Section of Chemical Education, its committee on Chemical Education, consisting of Neil E. Gordon, B. S. Hopkins, J. R. Kuebler, L. W. Mattern, L. C. Newell, W. D. Richardson, R. E. Rose, Walter Schmidt, W. Segerbloom, and R. E. Swain was made a committee of the Society.

The following rules suggested by the Supervisory Committee on Standard Methods of Analysis were read to the Council, and by the Council referred to the Executive Committee for study and approval. The Executive Committee on the following day took up these rules and unanimously adopted them as the rules of the Society:

RULES RELATING TO COMMITTEES OF THE SOCIETY AND OF ITS DIVISIONS AND SECTIONS HAVING TO DO WITH THE STANDARDIZATION OF METHODS OF ANALYSIS

For earlier rules see Proc. 1910, p. 106, and 1917, p. 97.

- 1. The Supervisory Committee on Standard Methods of Chemical Analysis shall remain as heretofore under the control of the Council but with power to approve or reject reports presented to it, without submitting its decisions to the Council for final action.
- 2. The Supervisory Committee shall consist of a nucleus of five (5) members no one of whom shall be a member of one of the subordinate committees hereinafter referred to unless he be already a member of the nucleus of the Supervisory Committee or become so by appointment. In the latter event he shall cease to be a member of the subordinate committee unless he happens to be its chairman.

In addition, the chairmen of committees in any way subject to its control and not members of the nucleus shall have the right to deliberate and vote with it concerning the work of their respective committees and shall be to such extent members of the Supervisory Committee.

- 3. The nucleus of five members may exercise the right to appoint, subject to its sole jurisdiction sub-committees to deal with methods of analysis that do not fall within the province of existing committees of the Society or of its Divisions or Sections.
- 4. All committees of the Society and of its Divisions and Sections, as well as sub-committees of the Supervisory Committee that are charged with recommending standard methods of analysis, shall submit their final reports to the Supervisory Committee for consideration.
  - 5. The Supervisory Committee shall:
    - (a) Exercise control of the work of all subordinate committees to the extent of preventing duplication of work and insuring consistency in the form of publication of reports.
    - (b) Examine all reports submitted to it that are final in the sense of definitely recommending methods or parts of methods for general use. This involves the right to reject entirely

such reports or to return them to the committee from which they emanate for such revision as may seem called for. It is assumed that no unduly arbitrary action will be taken in either of these directions, but that any decision rendered will be with a view to uphold the reputation of American chemists and the dignity of the Society. Any member of the Supervisory Committee may seek advice from experts of his own choice, regarding a report submitted to the committee.

- 6. Divisional or Sectional committees charged with recommending methods of analysis shall have full power, under the control of their respective Divisions or Sections, to initiate and prosecute work, and to publish, without referring to the Supervisory Committee, reports of progress and methods that are offered as tentative only. Final reports, however, or such as definitely recommend methods or parts of methods for general use shall be submitted by the chairman of the recommending committee to the Supervisory Committee for special consideration. Only on approval by that committee, except as hereinafter provided for, may such reports be published, subject to the usual submission to the editor of one or another of the Society's publications.
- 7. If the Supervisory Committee fails within three months to approve or reject a report submitted to it, the President of the Society (acting with the advice of the editors-in-chief of the Society's publications and of the chairman of the Division or Section concerned) shall be the final judge of its disposition. Similar disposition shall be made of reports that receive a tie vote in the Supervisory Committee. Acceptance or rejection within the time limit by the Supervisory Committee shall be final.
- 8. Final reports, if published, shall appear as emanating from the particular Division, Section, or sub-committee concerned, with the approval attached of the Supervisory Committee (or of the President of the Society in lieu of approval by the Supervisory Committee as called for in the foregoing rule 7) and they shall be signed by or appear under the names of a majority of the committee which prepared them, accompanied by a statement of the vote by which adopted.
- 9. Divisions or Sections of the Society may in their judgment appoint other general committees vested with power to appoint and control sub-committees within the Division or Section (referred to hereinafter as committees of first rank) or separate coördinate committees for different kinds of analytical work, but in the former case only the chairman of the committee of first rank shall have the restricted membership in the Supervisory Committee set forth in rule 2, paragraph 2.
- 10. The chairmen of all divisional or sectional committees of first rank shall, before a given line of work is undertaken, notify the chairman of the Supervisory Committee of the character and scope of the contemplated work, in order that duplication by different Divisions and Sections may be avoided. In case of impending duplication and subsequent inability of the Divisions or Sections interested to come to an agreement, the matter shall be decided by the Supervisory Committee.
- 11. In order to aid the chairman of the Supervisory Committee in the preparation of his annual report to the Council, the chairman of all divisional, sectional, and special committees shall each year submit to the Supervisory Committee a brief report of work in progress or about to be undertaken in their respective committees.

Said chairmen shall further report to the chairman of the Supervisory Committee at the earliest possible moment the correct names of their committees and sub-committees with a list of their members, and shall notify him of all changes made.

- 12. Joint committees of the Society with other societies shall report to the Supervisory Committee in the same way as prescribed in rules 6, 10, and 11, and the senior member by appointment from the American Chemical Society shall have the same rights and privileges in the Supervisory Committee as a chairman of a divisional or sectional committee.
- 13. The Supervisory Committee shall not approve any method of analysis which has been approved or adopted by another organization unless the method has been given a thorough and independent trial by a duly constituted committee within the American Chemical Society.
- 14. In order that Rules 1–13 may be brought promptly to the attention of all committees whose reports are subject to approval by the Supervisory Committee, the Secretary of the Society shall send copies of them to all newly elected Secretaries of Divisions and Sections accompanied by a request that they be transmitted to the chairmen of all committees on methods of analysis of their respective Divisions or Sections. The Secretary of the Society shall also send copies of the rules to the chairmen of newly appointed general committees of the Society that are charged with the formulation of standard methods of analysis.

All previous resolutions conflicting in part or wholly with the foregoing rules are hereby repealed. In promulgating the foregoing rules the Council wishes it understood that the Society does not contemplate making the use of such methods as may be recommended by its committees obligatory on any one, and, further, that no method is to be considered as final but simply as representing the best that can be done at the stated time. It is expected as a matter of course that revision will be exercised as knowledge and experience grow.

It was voted that new student memberships may begin on September 1st instead of on January 1st, in which case the dues will be \$3.50 for the last third of the year. Jour-

nals will be sent from September 1st, provided that back journals from that date are available.

A. B. Lamb was reëlected Editor of the Journal of the American Chemical Society, H. E. Howe, Editor of Industrial and Engineering Chemistry, W. A. Noyes, Editor of Scientific Monographs, and H. E. Howe, Editor of Technologic Monographs.

The following by-laws were passed:

Add to By-Law 3 the following two paragraphs:

There shall be an Executive Committee of the Council consisting of the immediate Past-President, the President, the Secretary, the Treasurer, the Editor of the Journal of the American Chemical Society, the Editor of Industrial and Engineering Chemistry, the Editor of Chemical Abstracts, and three Councilors, one to be elected each year for a term of three years, by ballot, at the annual meeting. A Councilor so elected shall remain a Councilor during his term of office on the committee.

The Executive Committee so constituted shall have full authority to act ad interim for and on behalf of the Council in all matters of national policy or import, shall serve in an advisory capacity in connection with matters coming before the Council, and shall exercise in addition the usual functions of an Executive Committee,

#### BY-LAW 22

The Directors shall be elected from districts arranged as nearly as possible to obtain equitable representation. At the time of election the Director shall reside or be a member of a section within the geographical limits of his district but shall not lose office by removal therefrom. Each local section, or any group of twenty-five members in good standing, within the district shall have the privilege of nominating one Director every three years, or whenever a vacancy occurs in their representation. For this purpose six districts are created as follows:

1st District. Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut and Canada.

2nd District. New York and New Jersey.

3rd District. Pennsylvania, Delaware, and Ohio.

4th District, Ålabama, Arkansas, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

5th District. Illinois, Indiana, Michigan, and Wisconsin.

6th District. Alaska, Arizona, California, Colorado, Hawaii, Idaho, Iowa, Kansas, Minnesota, Missouri, Montana, Nebraska, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming.

Necessary traveling and hotel expenses of Directors incurred in attending meetings of the board, other than those held at the time of general meetings, shall be paid by the Society.

The following changes in the Constitution being duly signed by five members of the Council, were recommended to the membership for passage:

Change Article IV, Section 4, Paragraph 8, of the Constitution now reading as follows:

In like manner, on or before November I, the Secretary shall mail to each member of the Council a blank upon which the Councilor shall be entitled to express his choice for two directors. From the nominations so received, the Secretary shall mail to the Council the names of the four persons who shall have been certified as having received the greatest number of nominating ballots for the office of director, and the Council shall elect two directors from these candidates, by mail ballot, at least one week before the end of the year.

to read:

On or before October 1 of each year the Secretary shall request each local section (entitled as provided in By-Law 22) to nominate a candidate for director, which nomination shall reach him on or before November 20 to be valid. The Secretary shall mail to the Council the names of the nominees so received and the Council shall elect one Director from each of two districts from among these candidates, by mail ballot, at least one week before the end of the year.

Add to Article IV, Section 5 (c) of the Constitution the provision:

If reflected, an Editor shall be elected by the Council to serve a term of three years, beginning with the first day of January, or until his successor shall have been duly chosen.

It was voted that the names of the two Councilors already on the Advisory Committee be continued on the Executive Committee. George D. Rosengarten was then elected the third member of this Committee.

It was voted that the Advisory Committee be given a vote of thanks in recognition of their excellent work in connection with changes in the by-laws brought about through the recommendation of the Committee on Society Procedure.

It was voted that it is the sense of the Council that the Council is not too large as at present organized.

It was voted that the name of the Leather Division be changed to "Division of Leather and Gelatin Chemistry."

It was voted to lay upon the table the motion of the Chairman and Secretary of the Leather Division permitting the presentation of papers by non-members at the option of the chairmen and secretaries of Divisions, with the suggestion that this matter be considered by the group of divisional officers. It was later voted to amend the vote passed at Pittsburgh regarding papers by non-members, so that it shall read as follows:

Papers by non-members may be placed on the program only when of unusual importance, and then only with the joint approval of the Secretary of the Division and the Secretary of the Society, except papers invited by chairmen and secretaries of Divisions, and such papers shall be so designated on the program.

It was voted that the Council approve the action of the Secretary so far taken in limiting papers of non-members and instruct him to continue the present policy of the Council, except as provided in the preceding motion.

The following resolution was presented by Professor E. C. Bingham, Chairman of the Metric System Committee, and was adopted:

In view of the earnest effort of the scientific, medical, pharmaceutical, and engineering societies of America in favor of the gradual adoption of the metric system, the Council of the American Chemical Society regrets the action of the U. S. Public Health Service and the War Department in making specifications for reagent chemicals hereafter in avoirdupois and apothecary units.

It was voted that the officers of the Society be complimented upon having accomplished so wide a distribution of our conferences.

It was voted that the Council encourage the holding of intersectional meetings with Section C of the American Association for the Advancement of Science.

The Council then discussed for some two hours the question of intersectional meetings and classified membership without action.

A vote of thanks was passed to those in Milwaukee who had made the meeting so successful.

The Council then adjourned.

CHARLES L. PARSONS, Secretary

Y. Wood, Frank J., 153 Joralemon St., Brooklyn, N. Y.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

#### ALABAMA SECTION

The regular monthly meeting of the Section occurred on October 6, at the Hillman Hotel, Birmingham, Alabama. The following program was presented: "Purification of Benzol," by S. S. Heide; "Quality of Coke in Reference to Blast Furnace," by W. H. Oldham; and "Electrolytic Manufacture of Phosphorus Products," by Theo. Swann.

HARRY BURN, Secretary

#### AMES SECTION

On June 12, W. Lash Miller, of the University of Toronto, gave a short illustrated talk before the members of the Section, his subject being "The Development of Alchemy."

R. B. WAITE, Secretary

#### CALIFORNIA SECTION

The 141st regular meeting of the Section was held on September 7, at the Engineers' Club, San Francisco, Cal. The following program was presented: "The Synthesis of Ammonia from Its Elements," by A. R. Olson; and "Peculiarities in Reactions of Unsaturated Carbon Compounds," by T. D. Stewart, both of the University of California.

L. H. Duschak, Secretary

#### CHICAGO SECTION

The regular meeting of the Section was held on September 21, at the City Club, Chicago. The address of the evening was by Carl S. Miner, of The Miner Laboratories, Chicago, Ill., his subject being "Furfural—The Story of an Industrial Research." The usual group meetings were held.

On October 19, A. M. Buswell, chief of the Illinois State Water Survey, addressed the members of the Section, his subject being "Sewage Purification: A Chemical Manufacturing Process."

Lee F. Supple, Secretary

#### DETROIT SECTION

At a joint meeting of the Associated Technical Societies of Detroit, held on October 26 under the auspices of the Local Section of the American Chemical Society, Edwin E. Slosson, of Washington, D. C., spoke on "Economic Independence of the United States."

J. D. PATERSON, Secretary

#### INDIANA SECTION

On October 12, W. D. Harkins, of the University of Chicago, addressed the meeting of the Section, his subject being "The Reality of the Atom. Photograph of Atom Tracks and Atomic Collisions."

H. A. Showle, Secretary

#### IOWA SECTION

The first meeting of the season was held on October 17, when the following program was presented: "A Report on the Milwaukee Meeting," by Edward Bartow; "The Influence of Gum Arabic upon the Catalysis of Methyl Acetate," by J. N. Pearce; and "A Report on Progress in the Determination of Solubilities," by P. A. Bond.

G. H. COLEMAN, Secretary

# KANSAS CITY SECTION

On September 21, the local Section joined with the University of Kansas and the Kansas Academy of Science in a celebration in honor of Edgar Henry Summerfield Bailey upon the completion of his fortieth year of service as professor of chemistry at the University of Kansas.

L. E. Clark, Secretary

# LEHIGH VALLEY SECTION

On September 28, the Section was addressed by Newton Perrins, of the Eastman Kodak Co., who spoke on "Curious Patents."

On October 26, James Kendall, of Columbia University, spoke to the members of the Section, his subject being "Isotopes." R. H. Bogub, Secretary

# LEXINGTON SECTION

The 89th meeting of the Section was held on October 4, at the University of Kentucky, Lexington, Ky. A report on the annual meeting of the Society at Milwaukee was made by J. S. McHargue.

O. M. Shedd, Secretary

#### LOUISVILLE SECTION

On September 19, the local Section held a meeting to discuss plans for the year's meetings and interesting new members in the Society.

C. E. Geiger, Secretary

#### NEBRASKA SECTION

At the 110th meeting of the Section held on September 18, E. C. Franklin, president of the American Chemical Society, spoke on "The Ammonia System of Acids, Bases and Salts."

S. B. Arenson, Secretary

#### NEW HAVEN SECTION

The first fall meeting of the Section occurred on October 17, when James W. Mc-Bain, of the University of Bristol, spoke on "A Study of Soap Solutions and its Bearing Upon Colloid Chemistry."

BLAIR SAXTON, Secretary

#### NEW YORK SECTION

At the meeting of the Section, held on October 5, the following program was presented: "Vitamins as Factors in Food Values," by Henry C. Sherman, of Columbia University; "The Manufacture and Uses of Invert Sugar," by Stroud Jordan, of the Henry Heide Company; "Some Salient Points in Sugar Manufacture and Economics," by David L. Davoll, of Arbuckle Brothers; and "Bread and its Relation to our Diet," by F. C. Weber, of the Fleischmann Laboratory.

Benjamin T. Brooks, Secretary

#### NORTHEASTERN SECTION

The 187th meeting of the Section occurred on October 15, when James W. McBain, of the University of Bristol, spoke upon "A Study of Soap Solutions and its bearing Upon Colloid Chemistry."

E. B. Millard, Secretary

#### OMAHA SECTION

The regular meeting of the Section was held on September 4, at Creighton University, Omaha, Nebraska. The following papers were given: "A Biography of Dalton," by Rev. Father Hickey, and "Milk Born Infection (Illustrated)," by R. N. Perkins.

The meeting of the Section, held on October 5, was addressed by A. H. Sabin, on the subject of "Paints."

R. N. Perkins, Secretary

# PITTSBURGH SECTION

The regular meeting of the Section occurred on September 20. A written report by James O. Handy, on the Milwaukee meeting, was read. It was voted that the Pittsburgh Section grant waivers on Blair County to the newly formed central Pennsylvania Section. Several business matters were considered by the meeting.

On October 18, Richard Bishop Moore, of the Dorr Company, New York City, addressed the members of the Section, his subject being "Newly Discovered and Undiscovered Elements."

E. S. Stateler, Secretary

#### ROCHESTER SECTION

On September 29, the Rochester and Syracuse Sections held a joint outing at the Geneva Experiment Station. In addition to the various amusements presented, an illustrated lecture was given by D. D. Van Slyke, of the Rockefeller Institute, his subject being "Factors Controlling the Distribution of Water and Electrolytes in the Blood."

ERLE M. BILLINGS, Secretary

# SAINT LOUIS SECTION

At the meeting of the Section, held on October 1, O. S. Ledman, of the Luyties Pharmacy Company, gave a paper on "The Homeopathic Laboratory." Reports on the Milwaukee meeting by the local councilors were made.

H. A. Carlton, Secretary

#### SOUTHERN CALIFORNIA SECTION

On July 26, W. Lash Miller, of Toronto, Canada, spoke before the meeting of the Section, his subject being "The Method of Willard Gibbs in Chemical Thermo-Dynamics."

At a joint session by the Southern California and California Sections, held on September 19, the following program was presented: "New Studies in Nitrogen Fixation," by C. B. Lipman; "Present Status of Chemical Criteria in Soil Fertility Investigations," by John Burd; "The Determination of Calcium," by Wm. Conger Morgan; "Critical Solution Temperatures," by G. Ross Robertson; "A Study of Pressure and Temperature Effects on Petroleum Emulsions," by Laird J. Stabler; "Butyrin," by Leroy S. Weatherby; "The Vapor Pressure of Monatomic Elements," by Russell H. Miller; "A System of Qualitative Analysis Including the Rare Elements," by A. A. Noyes and W. C. Bray; "Dissociation of Hydrogen Cyanide at High Temperatures," by R. M. Badger; "The Rate of Dissociation of Sulphuryl Chloride," by D. F. Smith; "Studies on the Chemical Behaviour and the Physical Properties of Insulin," by G. A. Alles and A. L. Raymond; "Some New Experiments on the Oxidation Reduction Theory of Contact Catalysis," by A. F. Benton and P. H. Emmett.

On October 12, Gustave Egloff, of the Universal Oil Products Co., of Chicago, spoke on "The Refining of Petroleum Oil."

MARK WALKER, Secretary

#### UNIVERSITY OF ILLINOIS SECTION

At the regular monthly meeting of the Section, held on October 16, R. E. Greenfield, of the Illinois State Water Survey, spoke on "Investigation of Pollution of the Illinois River."

D. T. ENGLIS, Secretary

#### UNIVERSITY OF MISSOURI SECTION

The 117th meeting of the Section was held on September 20, when P. A. Shaffer, of Washington University, St. Louis, Mo., spoke on "The Preparation and Properties of Insulin."

H. E. French. Secretary

#### VIRGINIA SECTION

On October 12, E. R. Weidlein, director of the Mellon Institute, Pittsburgh, Pa., addressed the Section on "Science and Industry."

On October 18, 19 and 20, Edwin E. Slosson, at the invitation of the Section and the University of Virginia, spoke on the following subjects, respectively: "Creative Chemistry," "The Changing Mind of Man," and "Science Remaking Everyday Life."

LLOYD C. BIRD, Secretary

#### WISCONSIN SECTION

The 127th regular meeting of the Section occurred on October 10, when H. B. Wahlin, of the University of Wisconsin, spoke on "The Nature of Gaseous Ionization."

FARRINGTON DANIELS, Secretary

#### WASHINGTON, D. C., SECTION

The 344th regular meeting of the Section was held on October 11. The address of the evening was by E. W. Washburn, of the National Research Council, who spoke on "Physical Chemistry and Ceramics."

J. B. Reed, Secretary

# WESTERN NEW YORK SECTION

At the meeting of the Section, held on October 16, a general discussion of the following subjects was carried on: "Were You Properly Educated?" "Are Future Chemists Being Properly Educated?" and "Why is Chemistry Being Taught as It Is?"

R. W. HESS, Secretary

#### DECEASED

Pierre Mali, 25 Madison Ave., New York, N. Y. Died, October 4, 1923.

Benjamin S. Neuhausen, 2213 Madison Ave., Baltimore, Md. Died, August 20, 1923.

Frank D. Simons, U. S. Appraiser's Public Store Building, Baltimore, Md. Died, October 5, 1923.

# Proceedings

# COUNCIL

Dr. E. C. Franklin, President of the American Chemical Society, appointed Edward Mallinkrodt to represent the Society at the inauguration of Herbert Spencer Hadley as chancellor of Washington University, St. Louis, Mo. Dr. Franklin also appointed W. F. Hillebrand to represent the Society at the inauguration of William Mather Lewis as president of George Washington University, Washington, D. C.

# MEMBERS ELECTED BETWEEN OCTOBER 15 AND NOVEMBER 15, 1923

Baker, Thaddeus H., 7212 Ridgeland Ave., Chicago, Ill.

Bakken, A. C. Aluminum Club, New Kensington, Pa.

Baril, Olier L., 1 Cottage St., Spencer, Mass.

Barrell, Edward Park, 430 East Rich Ave., De Land, Fla.

Beebe, Ralph A., Gateway Club, Princeton, N. J.

Binswanger, L. Clarence, 829 North 3rd St., Philadelphia, Pa.

Blatchford, Rev. John A., Holy Cross College, Worcester, Mass.

Bloomsburg, Harry E., 1004 Furnald Hall, Columbia University, New York City,

Bodman, J. W., Room 701, 360 N. Michigan Blvd., Chicago, Ill.

Bosonitz, John J., 211 University St., W. Lafayette, Ind.

Branham, Joseph Russell, Cobb Chem. Lab., University of Virginia, University, Va.

Brubaker, Merlin, 1104 West Clark St., Urbana, Ill.

Bull, H. Marie, Albion College, Library, Albion, Mich.

Burns, A. L., 225 Custom House, New Orleans, La.

Burroughs, A. M., 12 Whitten Hall, University of Missouri, Columbia, Mo.

Caeser, David, 1501 Eastern Parkway, Brooklyn, N. Y.

Case, Jarvis Dixon, 23 Harvard St., Hartford, Conn.

Chittum, John W., 5517 Dorchester Ave., Chicago, III.

Coe, Dana G., Soils Department, Iowa State College, Ames, Iowa.

Davidson, Glen M., 515 W. 111th St., New York City.

de Ganahl, Carl, Medway Oil Storage & Refg. Co., Grain Halt, Isle of Grain, Kent, England.

de Goey, Cornelius, American Wringer Co., Woonsocket, R. I.

Donaldson, David, 60 Polwarth Terrace, Edinburgh, Scotland.

Drake, Richard C., 602 E. Stoughton, Champaign, Ill.

# MEETINGS OF THE SECTIONS

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

#### AMES SECTION

On the evening of October 25, A. M. Buswell, chief of the Illinois State Water Survey, addressed the Section. His subject was "Sewage Purification, a Chemical Manufacturing Process."

R. B. Waite, Secretary

#### ARKANSAS SECTION

The fall meeting of the Section was held at Little Rock, Arkansas, on November 8, 1923. The following program was presented: "Diamonds Set in Platinum," by Frank W. Gibb; "Recent Advances in our Understanding of Insecticides," by George Becker; "Industrial Alcohol," by Ruel J. Manning; "Origin of Arkansas Bauxite," by George Banner; and "Insulin and the Diabetic," by J. W. Read.

The following officers for 1923-1924 were elected by the Section: J. W. Johnson, chairman; G. W. Roark, Jr., vice chairman; Harrison Hale, councilor; H. G. Lewis, treasurer; and J. W. Read, secretary.

J. W. Read, Secretary

#### CALIFORNIA SECTION

The 142nd regular meeting of the Section occurred on October 12, when Jerome Alexander, of the National Research Council, Washington, D. C., spoke on "Bridging the Gap between Masses and Molecules."

The 143rd regular meeting of the Section was held on November 2, when the following addresses were given: "The Electrolytic Separation of Amino Acids," by C. L. A. Schmidt; and "The Chemistry of Humins," by G. O. Burr—both of the University of California.

L. H. Duschar, Secretary

#### CHICAGO SECTION

On November 23, Raymond F. Bacon, of the Standard Oil Company of Indiana, addressed the meeting of the Section, his subject being "Sulfur." The usual group meetings occurred after the lecture.

Lee F. Supple, Secretary

#### CINCINNATI SECTION

The first fall meeting of the Section was held on October 23, when James W. McBain, of the University of Bristol, Bristol, England, spoke on "A Study of Soap Solutions and Its Bearing Upon Colloid Chemistry."

The 261st regular meeting occurred on November 14, with the following program: "The Liberation of Hydrogen from Carbon Compounds," by H. S. Fry; and "The Composition of Marine Animal Oils," by C. L. Milligan—both of the University of Cincinnati.

A. O. SNODDY, Secretary

#### CLEVELAND SECTION

The first fall meeting of the Section was held on October 23, when Elbert L. Hyde addressed the members on the subject of "Patents."

H. S. BOOTH, Secretary

#### COLORADO SECTION

At the regular meeting of the Section, held on September 26, the following officers were elected: S. J. Osborn, chairman; L. D. Roberts, vice chairman; D. K. Proffitt, secretary; R. G. Gustavson, treasurer; and W. D. Engle, councilor.

D. K. PROFFITT, Secretary

#### COLUMBUS SECTION

On October 31, C. W. Foulk addressed the members of the Section, his subject being "Some Problems in the Industrial Use of Water."

Jesse E. Day, Secretary

## CONNECTICUT VALLEY SECTION

At the meeting of the Section, held on October 6, at Westfield, Mass., Dennis, Calhune, of the Worcester Polytechnic Institute, spoke on "Recent Developments in Electro-Chemistry."

On November 3, Arthur J. Hopkins, of Amherst College, addressed the members of the Section, at Hartford, Conn., his subject being "Traces of Alchemy." At this meeting, the following officers were elected for the Section: G. Albert Hill, chairman; George B. Hogaboom, vice chairman; E. W. Lovering, secretary; Henry McDonald, Jr., treasurer; C. R. Hoover and J. S. Chamberlain, councilors; H. Edward Wells, V. K. Krieble and J. A. Newlands, executive committee.

E. W. Lovering, Secretary

#### DELAWARE SECTION

The fall season of the Section was inaugurated on September 26, with an informal get-together dinner followed by an address by Graham Edgar of the University of Virginia. His subject was "Atomic Weights and Isotopes."

On October 18, W. M. Corse, of the National Research Council, Washington, D. C., addressed the members of the Section, his subject being "Nickel, Its Metallurgy and Uses."

At a meeting of the Section, held on November 21, Fred E. Wright, of the Geophysical Laboratory, Washington, D. C., addressed the members, his subject being "The Purpose and Scope of the Experiment in Geology."

J. W. Stillman, Secretary

#### EASTERN NEW YORK SECTION

At the regular meeting of the Section, held on November 2, Paul E. Howe, of the Rockefeller Institute of Medical Research, delivered a lecture on the subject, "Some Observations on the Globulins of the Blood."

On November 23, Karl T. Compton, of Princeton University, spoke on the subject, "The Distribution of Electric Charge and Mass in Molecules." H. A. Jones, Secretary

#### HAWAIIAN SECTION

The following officers for the Section were elected at its annual meeting held on October 24: Guy R. Stewart, chairman; William Weinrich, vice chairman; R. Q. Smith, secretary; D. Kirschman, treasurer; and Will T. McGeorge, councilor. At this meeting, F. F. Jewett, of Oberlin College, gave a short address on his experiences as a student and teacher.

Ronald Q. Smith, Secretary

#### INDIANA SECTION

The regular monthly meeting of the Section occurred on November 9, when A. B. Davis, of Cincinnati, Ohio, spoke to the members, his subject being "Advances in the Manufacture of Dry Colors and Their Application."

HORACE A. SHONLE, Secretary

# LEHIGH VALLEY SECTION

On November 22, Duff Abrams, of the Lewis Institute, Chicago, addressed the members of the Section, his subject being "Cements." ROBERT H. BOGUE, Secretary

# LEXINGTON SECTION

The 90th meeting of the Section was held on November 14. On that occasion, G. D. Buckner, of the Experiment Station, Lexington, Ky., spoke on the subject, "Scientific Meetings in France."

O. M. Shedd, Secretary

#### LOUISIANA SECTION

The first meeting of the season occurred on October 19, when S. A. Mahood, of of Tulane University, addressed the Section, his subject being "The Preparation of a New Dye—The Furfural Analog of Benzoflavine or Dimethyl-Furyl Acridine Hydrochloride."

On November 7, a dinner was given by members of the Section in honor of visiting members of the chemical fraternity—C. A. Browne, chief of U. S. Bureau of Chemistry, Washington, D. C., and R. E. Doolittle, chief of the central district, Bureau of Chemistry, U. S. Department of Agriculture.

H. R. Struens, Secretary

#### MAINE SECTION

A meeting of the Section was held on November 16, when H. E. Thompson spoke on "Application of Chemistry to Medicine."

L. G. Jenness, Secretary

#### MARYLAND SECTION

At the meeting of the Section, held on October 26, the following officers were elected for the ensuing year: Carl Haner, chairman; Neil E. Gordon, vice chairman; Adolph Harvitt, secretary-treasurer; A. A. Backhaus, A. E. Marshall and M. D. Scott, councilors; S. T. Powell, W. B. D. Penniman, J. C. W. Frazer, F. M. Boyles, W. A. Taylor and A. H. Warth, executive committee.

The Section held a joint meeting with the Baltimore Gas and Electric Association on November 21, when F. W. Speer, Jr., of the Koppers Company, spoke on "Liquid Purification of Illuminating Gas."

ADDLEH HARVITT, Secretary

#### MIDLAND SECTION

The 19th regular meeting of the Section occurred on October 19, when R. B. Moore, of the Dorr Engineering Company, New York City, gave an address on "Helium: Its History, Production, and Commercial Uses."

John A. Gann, Secretary

# MINNESOTA SECTION

On October 3, the Section heard reports on the Council meeting held at Milwaukee in September. Nominations for offices of the national society were made.

L. M. HENDERSON, Secretary

## NASHVILLE SECTION

The first fall meeting of the Section was held on October 26, and was addressed by J. W. Sample, state chemist of Tennessee, on the subject, "The Chemist in Regulatory Work."

H. A. Webb, Secretary

# NEBRASKA SECTION

The 111th meeting of the Section occurred on October 24, at the University of Nebraska, and was addressed by Charles W. Rodewald on "Synthetic Drugs: Some Theories of Physiological Action."

S. B. Arenson, Secretary

# NEW HAVEN SECTION

At the regular meeting of the Section, held on November 21, C. H. Davis, of the American Brass Co., spoke on "Spectroscope Analysis."

BLAIR SAXTON, Secretary

#### NEW YORK SECTION

Taking as his subject, "Bonds Between Atoms in Molecules," Lauder W. Jones, of Princeton University, addressed the meeting of the Section, November 9.

BENJAMIN T. BROOKS, Secretary

#### NORTHEASTERN SECTION

The 188th meeting of the Section was held on November 9, when the following addresses were given: "The Manufacture of Sodium Hydrosulfite," by L. A. Pratt, director of research, Merrimac Chemical Company; and "A Recent Improvement in Sulfuric Acid Manufacture," by F. G. Stantial, vice president of the Merrimac Chemical Co.

12. B. MILLARD, Secretary

#### NORTHERN INDIANA SECTION

The local Section held a joint meeting with the American Society for Steel Treating on October 24. The following addresses were made: "The Investigation of the Patigue of Metals," by Prof. Moore of the University of Illinois; and "The Relation Between the Experienced Employer and the Young Apprentice," by Walter F. Newhouse, of the Saranac Machinery Co.

At the regular meeting of the Section, held on November 14, W. D. Harkins, of the University of Chicago, spoke on "The Structure of the Atom."

V. C. BIDLACK, Steretury

#### NORTHERN WEST VIRGINIA SECTION

The first fall meeting of the Section occurred on October 19, when E. L. Rogers, of the Fairmont Normal School, Fairmont, W. Va., addressed the members on the subject, "Research and Chemical Education."

E. P. DEATRICK, Secretary

# OMAHA SECTION

At a meeting of the Section, held on November 6, M. V. Robins spoke on "The Weather Bureau and its Worth."

R. N. PERKINS, Secretary

## OREGON SECTION

The regular meeting of the Section was held on October 27, at Reed College, Portland, Oregon. The speaker of the evening was Arthur F. Scott, of Reed College, whose subject was "Fajans, of Munich, and Some of his Recent Contributions to Chemical Theory."

At this meeting the following officers were elected: Harry G. Miller, president; E. C. Gilbert, vice president; F. A. Gilfillan, secretary-treasurer; and R. K. Strong, councilor.

F. A. GILFILLAN, Secretary

#### PHILADELPHIA SECTION

At the first fall meeting of the Section, S. Earle Hoover, of the Hoover Construction Co., Philadelphia, Pa., addressed the members at an informal after-dinner talk urging support of the eighteenth amendment. In the evening, Henry Arnstein addressed the meeting on the subject, "The History and Practical Achievements of the Fermentation Sciences."

On November 15, Arthur Wright, of Filtration Engineers, Inc., New York City, spoke before the meeting of the Section, his subject being "Progress in Filtration and Impediments Thereto."

ELMER C. BERTOLET, Secretary

# PITTSBURGH SECTION

On November 15, R. E. Hall, of the U. S. Bureau of Mines, addressed the meeting of the Section, his subject being "Some Phases of Boiler-Water Chemistry."

E. S. STATELER, Secretary

#### PUGET SOUND SECTION

The first fall meeting of the Section was held on November 1. The speaker was Waldo Seman, of the University of Washington, his subject being "Why is an Oxime?"

W. L. Beuschlein, Secretary

# PURDUE SECTION

The second regular meeting of the Purdue Section for the year was addressed by G. H. A. Clowes, of the Eli Lilly Company of Indianapolis, Ind., his subject being "The Preparation and Properties of Insulin."

The first fall meeting of the Section occurred on October 11, when W. D. Harkins, of the University of Chicago, spoke on "The Building and Disintegration of Atoms, and the Photography of Atomic Collisions."

M. G. Mellon, Secretary

#### ROCHESTER SECTION

On October 15, Gustave W. Thompson, of the National Lead Co., spoke to the members of the Section on the subject, "Lead and Lead Compounds—A Retrospect."

The 189th meeting of the Section occurred on November 5, when Frank C. Whitmore spoke on "The Human Side of Mercury."

On November 20, the following addresses were presented before the meeting of the Section: "Science Education in the University," by Rush Rhees, president of the University of Rochester; "Science Teaching in the Public Schools," by Herbert S. Weet, superintendent of public instruction; and "Training Personnel for Chemical Control in Industry," by John A. Randall, president of Mechanics Institute.

ERLE M. BILLINGS, Secretary

#### SAINT LOUIS SECTION

A paper, with demonstrations, entitled "The Physiological Assay of Drugs," was presented before the meeting of the Section held on November 5, by E. A. Ruddiman of the John T. Milliken Co.

H. A. Carlton, Secretary

#### SAVANNAH SECTION

The Section held its first fall meeting on October 11, when the following papers were read: "The Fertilizer Industry," by Benjamin F. Taylor; and "Nitrogen Content in Chamber Acid and its Relation to the Chamber Process," by Eli H. Armstrong. Twenty-two members and visitors were present.

On November 9, R. T. Stull gave an illustrated lecture before the meeting of the Section, his subject being "Kaolin and Bauxite Deposits of Georgia and their Uses in the Arts." The annual election of officers elected at this meeting resulted as follows: John W. Everson, chairman; J. C. Howard, vice chairman; Herbert S. Bailey, councilor; Herbert P. Strack, secretary-treasurer.

Herbert P. Strack, Secretary

#### SOUTHEAST TEXAS SECTION

The 22nd regular meeting of the Section occurred on October 20. A paper entitled, "Contact Sulfuric Acid Manufacture," was read by Thomas J. Sullivan.

P. S. TILSON, Secretary

#### SOUTHERN CALIFORNIA SECTION

On November 9, William Conger Morgan, of the University of California, Southern Branch, delivered a paper before the members of the Section. His subject was "Photo Synthesis."

MARK WALKE, Secretary

# SOUTH JERSEY SECTION

Taking as his subject, "Canning," W. D. Bigelow, of the National Canners' Association Research Laboratories, Washington, D. C., addressed the meeting of the Section, held on October 18.

W. Fletcher Twombly, Secretary

#### TOLEDO SECTION

At the 56th meeting of the Section, held on October 23, Arthur Fowle, of the Libbey-Owens Glass Co., Toledo, Ohio, gave a talk on "The Manufacture of Sheet Glass."

A regular meeting of the Section occurred on November 20, when W. B. Holmes, of the Ames Laboratories, Fremont, Ohio, spoke on "The Properties of Dental Cement."

W. E. RUTH, Secretary

# UNIVERSITY OF MICHIGAN SECTION

The first meeting of the year was held on October 25, when F. G. Novy spoke on "The Pasteur Centenary."

On November 9, Frank C. Whitmore, of Northwestern University, gave an address before the members of the Section, his subject being "Recent Developments in the Organic Chemistry of Mercury."

C. C. Meloche, Secretary

#### UNIVERSITY OF MISSOURI SECTION

The regular meeting of the Section, held on October 4, was addressed by R. T. Dufford, his subject being "Luminescence of Organic Magnesium Compounds."

H. E. FRENCH, Secretary

#### VERMONT SECTION

On October 26, Marston Taylor Bogert, of Columbia University, delivered a lecture, entitled "Perfumes and Perfumery," before the members of the Section. At this meeting, the following officers were elected: Elbridge C. Jacobs, chairman; Otto Weinstock, vice chairman; Ralph R. Read, secretary-treasurer; and S. Francis Howard, councilor.

RALPH R. READ, Secretary

#### VIRGINIA SECTION

At the meeting of the Section, held on November 9, W. D. Collins, of the United States Geological Survey, gave an address, his subject being "The Industrial Value of the Soft Waters of the South."

L. C. Bird, Secretary

# WASHINGTON, D. C. SECTION

On November 8, the Section elected the following officers for 1924: R. S. McBride, president; J. B. Reed, secretary; H. W. Houghton, treasurer; Wm. M. Clark, A. Seidell, R. B. Sosman and W. W. Skinner, councilors; V. K. Chestnut, Wm. Blum, S. C. Lind, L. H. Adams, E. T. Wherry and F. W. Smither, executive committee.

J. B. Rund, Secretary

# WESTERN NEW YORK SECTION

The second meeting of the Section occurred on November 20. The speaker of the evening was W. M. Corse, of the National Research Council, whose subject was "Nickel: Its Metallurgy, Properties and Uses."

R. W. Hess, Secretary

#### DECEASED

George H. Beaumont, 2865 Fairfax Road, Cleveland, O. Died, May 12, 1923. A. R. Ledoux, 99 John St., New York City. Died, October 25, 1923. W. C. Marckworth, c/o Pure Oil Co., Columbus, O. Jacob Rosenbloom, Jenkins Arcade, Pittsburgh, Pa. Died, September 25, 1923. Arthur L. Stark, 232 East Ave., Elyriu, O.
